to which ore must be crushed which is assumed to be the same in both classes of machines. (2) Amalgamation by thorough mixture, running the pulp over plates. (3) Amalgamation by running crushed ore over plates. (4) Concentration of tailing from No. 2. (5) Concentration of tailing from No. 3. (6) Cyanide extraction and concentration of tailing from No. 2, 3, 4, and 5.

For the sake of argument we will assume the saving of test No. 2 to be 85% representing the action of a 5-stamp unit. The question is, what percentage of saving must the single-unit battery maintain to be equally efficient, or, a cyanide annex being necessary, will this addition prove economical? The cyanide recovery in both cases may be assumed to be 90%. If the two types of mill made the same percentage of recovery by amalgamation, the preference would be for that crushing at the least expense, but it is doubtful if the single-unit will give as high recovery by amalgamation or cyanidation as the 5-stamp unit. Not having a chance to try the crushing capacity of the two types of mills it may be assumed that experience has shown the ratio to be about three to four; in other words the 5-stamp unit will crush three tons per day per stamp, while the single unit will crush four tons at the same expense. The expense and extraction sheet is as follows:

	Milling and Amalgamating.		Cyaniding.		Concentrating.	
Unit.	Milling.	Extraction.	Cost.	Extraction.	Cost.	Extraction.
5	...$1.35	85%	$1.15	90%	$0.30	90%
1	... 1.45	....	1.10	90%	0.30	90%

Table No. 1 shows the application of this cost-sheet to a free-milling or oxidized ore. To obtain the same profit per ton as the 5-stamp unit the single-unit need only amalgamate 60% of a $500 ore providing as stated above, the extraction by cyanide in both cases is 90%. As the ore increases in value so does the necessary extraction by the single unit. If the cyanide extraction is 80% in both cases we have Table 2, showing that the lower the cyanide extraction the higher must be the amalgamating efficiency of the single unit. For low-grade ores that will not pay for cyaniding the single unit will pay as well with a much less extraction by amalgamation. Table 3 shows the results when there is a wide difference in the cyanide extraction that is hardly to the credit of the single unit. For a concentrating ore the greater the amount saved as a concentrate, the more favorable the single unit will appear. A few actual examples may be profitably considered.

1. A quartz ore which by test 2 shows an extraction of 42% and by test 3, 25%. The extraction in the concentrate averages 91% of the tailing in both cases. The cyanide extraction is so low that it is out of the question. The ore averages $6. The cost of milling with the single unit is estimated at $1.10, with the 5-stamp unit $1.45. A profit of 25c. per ton in favor of the single unit is shown as below.

Single unit:	Extraction.	Cost.	Profit.
Amalgamation	$1.50	....	....
Concentration	4.10	....	....
Total	$5.60	$1.10	$4.50
Five unit:			
Amalgamation	$2.50	....	....
Concentration	3.20	....	....
Total	$5.70	$1.45	$4.25

2. An ore amalgamating 5% and yielding by concentration 1% in both cases, the cyanide extraction being 81% when the ore is reduced to 150 mesh and only 30% when ground to 20 mesh. The ore averages $18 per ton. Cost of milling $1.45 and $1.95 plus in each case 30c. for re-grinding. Cyanide treatment $1.55. The profit in favor of the single unit is equal to the difference in cost of crushing the ore.

Single unit:	Extraction.	Cost.	Profit.
Amalgamation	$0.90	....	....
Cyanidation	13.85	....	....
Total	$14.75	$3.30	$11.45
Five unit:			
Amalgamation	$0.90	....	....
Cyanidation	13.85	....	....
Total	$14.75	$3.80	$10.95

3. An ore amalgamating 83% by test 2, and 68% by test 3. The extraction by concentration is 61 and 58%; the cyanide extraction 78% in both cases. The ore averages $12 per ton. Cyanide cost $1.35 per ton. Milling cost $1.40 and $1.05, including concentrating. In this case the tailing will not pay to cyanide and the balance of profit is in favor of the 5-stamp unit.

Single unit:	Extraction.	Cost.	Profit.
Amalgamation	$8.15	....	....
Concentration	2.25	....	....
Total	$10.40	$1.05	$9.35
Five unit:			
Amalgamation	$9.95	....	....
Concentration	1.25	....	....
Total	$11.20	$1.40	$9.80

I have made out a pretty good case for the single-unit stamps but the point I wish to make is that before a final decision is made the ore must be thoroughly tested in such a way as will most nearly represent the actual conditions existing in practice, and the result worked out mathematically. If there appears to be little difference adopt the 5-stamp unit as being less cumbersome and needing less floor space and fewer working parts.

McKITTRICK-SUNSET OIL REGION, CALIFORNIA

California now stands first among the States in production of petroleum, which is its most valuable mineral product, gold now ranking second. In 1909 the State produced between 50,000,000 and 60,000,000 bbl. of oil, valued at about $30,000,000. This enormous production has naturally attracted general attention to the oilfields of the State, which are now being actively explored and exploited. A report on the McKittrick-Sunset oil region, in western Kern and eastern San Luis Obispo counties, prepared by Ralph Arnold and H. R. Johnson, has just been published by the United States Geological Survey as Bulletin 406. The region covered embraces about 1800 sq. mi., and includes the most productive territory of the McKittrick, Midway, and Sunset fields and the undeveloped or less developed Devils Den, Temblor, and Carrizo Plain districts. Large areas of public lands in this region have been withdrawn from entry pending legislation or re-classification. The recent report gives an account of the geography, topography, and general features of the region.

Geologic Bases of Mining Law

By Courtenay De Kalb

*The intricate and complex adjustments of right and equity necessitated as a condition for the peaceable utilization of the material of the earth, as distinguished from mere possession and occupancy of the surface, is the work of the mining lawyer. The concrete substance of the earth is the basis which underlies the whole body of the mining law. It is therefore evident that the facts of economic geology determine the essential validity of reasoning within this department of the law, and the ends of justice are subserved in proportion as the mining law proceeds from a correct conception of the phenomena and processes recognized in connection with the valuable materials found in the earth's superficial envelope. Primarily the legislator, and the judiciary which interprets the law in the face of specific facts, are concerned with phenomena, that is, with things as they are found to exist. The repetition of certain phenomena, such as the occurrence of metals in conjunction with other minerals in lodes, veins, and other deposits, presenting similar characteristics, leads to generalizations, and to anticipation of the recurrence of like phenomena as the exploration of the earth proceeds, and upon such probability of finding a continually increasing number of examples of already familiar geologic conditions laws are framed to dispose of and to safeguard human rights in the extraction of valuable mineral substances. It is well to keep in mind that we are nevertheless dealing with an aggregate of isolated facts of experience, from which natural laws may to some extent be deduced, and that the function of the lawyer is to elucidate concrete fact, while that of the judge is to determine what is the fact in each individual case. It is not natural law, nor the supposed results of natural law, that constitutes the concern of the body of man-made law, but the ascertainment and proper interpretation of phenomena. I believe it may be safely affirmed that the errors in mining law proceed largely from the human tendency to generalize too freely upon an insufficient accumulation of evidence. It is pleasing to the human mind to systematize, to trace out origins and the logical sequence of events. But as soon as we have set in order our knowledge of a set of conditions, and have declared in favor of a natural law apparently competent to explain them, we have closed our case, so to speak, and the decision thus reached acquires a hold upon the intellect which blinds it to the reception of new and discordant fact. The shackles of dogma limit the freedom of observation. I do not mean to imply that we should regard the geologic conditions we confront as erratic occurrences in a chaotic world, but it is necessary to disabuse oneself of the notion that finality has been reached in explaining the relations of rocks, ores, and other substances in the earth. The mining lawyer must preserve his pragmatic adaptability of thought.

On the other hand, a function of the geologist is to gather knowledge and correlate it for the deduction of laws and general principles. How far these may be accepted in the interpretation of phenomena for the meting out of justice is a problem of great difficulty. The preponderance of testimony is not a safe guide in such matters, and the weight of authority is hard to measure. The more important service of the economic geologist as an expert witness lies in pointing out facts which only a trained observer can recognize, and in demonstrating relationships which the non-technical man could not discover. The more of fact and the less of theory in his testimony, the more valuable it is for the purposes of the courts. Having frankly acknowledged that inferences from general principles are likely to lead to injustice in determination of right and equity, I may presume to venture with greater freedom into a consideration of certain large geologic conceptions which are fundamental.

We know the outer envelope of the earth to an exceedingly shallow depth. The deepest mine in the world has penetrated only 5300 ft. This is the Calumet & Hecla in Michigan. The mines which exceed 4000 ft. in depth are few. By the processes of erosion by winds and waters, aided by frosts and the sun's heat, rocks that were once deep-seated are now exposed to view. In a few places it is estimated that the rocks at present visible had certainly been buried to a depth of about eight miles. Accordingly it will be seen how limited has been our opportunity to gain a knowledge of the deeper portions of the earth. All we know is the mere upper shell, a small fraction of the rocky exterior, which is called the lithosphere. Concerning the rest all is speculation. The interior of the earth may be a homogeneous mass; or it may consist of materials segregated by reason of superior specific gravity. Some geologists maintain that the heavier metals must be concentrated toward the centre of the earth, which is therefore denominated the barysphere. The mean density of the earth is about five times as great as water; the density of the exterior part with which we are familiar is 2.6. That involves a specific gravity at the centre of 15 if the density were to progressively increase from the surface inward. It is conceivable that simple pressure acting upon a homogeneous mixture of materials of the same average chemical composition as the lithosphere could produce this result. It is absolutely certain, however it be accomplished, that the mass of the earth becomes progressively more dense toward the centre. It is not necessarily true, however, that the deeper interior of the earth is the source of the metals which we find concentrated into veins and other deposits. Even when the economic geologist speaks of the material found in veins as having a deep-seated origin he is still referring to relatively shallow depths. It is capable of mathematical demonstration that the pressure is so great as to close absolutely the spaces which we call capillary openings in the rocks at a depth of certainly no more than nine miles, and it is inconceivable that contributions of solution carrying mineral matter, or of volatile compounds of metals or other substances, can be derived from greater depths. The only exception to this statement is involved in the manifest

*Address delivered before the San Francisco Bar Association.

invasion of deeper-seated material during periods of mountain-making. An uplift of a great range of mountains, like the Andes, for example, giving an average elevation of as much as two miles, and in places reaching even four and five miles, shows that a vast amount of material below the non-porous lithosphere has flowed upward, and this, of course, has brought with it entrained gases, and water. Such solutions are called magmatic water, and they are active solvents for metals, and for metallic and earthy salts. In this way, through volcanic action, fresh material, capable of depositing minerals in fissures and open spaces in the rocks, is brought up from considerable depths, but it is important to note that there can be no continuous flow of such gases or solutions from the deeper masses of the earth's material that have closed in behind the portion which has thus invaded the upper shell of the earth.

Before proceeding farther with the argument for the probable source of the minerals in veins, it is well to point out that from the earliest periods in the history of the earth inequalities in pressure over various areas have resulted in uplifts and local eruptions of the deeper-seated material, forming continents and mountains. The erosion of the continental masses and mountain ranges has brought about a distribution of this material covering great areas with sands and gravels and silt deposits, and carrying dissolved matter into seas and oceans. The sands and gravels, technically called clastic material, have consolidated into sandstones and conglomerates, while by simple precipitation, and by the secretions of organic life, the dissolved matter has been thrown down in the form of limestones, deposits of chert, of salt, and of gypsum. The net result has been to cover the earth with such secondary deposits, the accumulation of ages having spread a great mantle of sedimentary rocks, aggregating in places many tens of thousands of feet. The average thickness of this mantle would be difficult to estimate, but it amounts to several miles. It varies extremely, and over large areas has either been removed by erosion, or never existed because of the high elevation. It must be noted also, that deeply buried sediments, under the influence of high temperature, and in the presence of the contained moisture, may become plastic and alter into crystalline rocks, resembling some of those which have consolidated from the interior magmas that have intruded from below. The whole mass of the superficial rocks of the earth, has, therefore, been derived from the upper portion of that original material which is loosely called volcanic, and in the aggregate it represents the average chemical composition of this primary matter. It contains the metals that were in that primary matter—no more and no less. But there has been a segregation of these constituents, so that some of the sedimentary rocks are lean and others relatively rich in minerals. None contain commercial quantities, but the significant fact is that the metals are there, and if solvents of sufficient power circulate through them these metals can be dissolved, and they will ultimately be precipitated under favorable conditions. In this way concentrations of metals can take place independently of any immediate volcanic agencies. The continual flow through rock pores of waters, containing carbonic acid gas, can thus dissolve metals and reprecipitate them in fissures, or in porous strata, and thus produce veins, masses, or beds of such a grade of valuable content as to admit of their economic exploitation. It is also true that a similar leaching of crystalline rocks of distinctly volcanic origin is constantly taking place. Thus it is seen that the filling of veins may occur through the agency of solutions circulating in the upper rocks, as well as from solutions derived from the deeper-seated volcanic magmas.

Much has been written concerning deposits due to a segregation of the metalliferous constituents of volcanic magmas. That such concentrations occur can not be doubted. In a few cases the segregation has been carried on to such an extent as to produce valuable masses of ore. Usually, however, such concentrations have been so feeble that subsequent additional concentration by solutions has been necessary to yield workable deposits. The recent development in America of immense low-grade deposits of copper minerals, known as disseminations in porphyry, has brought this class of ore into prominence. In a certain sense such deposits represent segregations, that is, they consist of magmas into which were originally concentrated considerable quantities of copper minerals. Subsequently the copper was leached downward from the surface enriching a zone at no great depth, so that it contains a workable amount of the metal.

From the foregoing it is clear that ore deposits are of many kinds, and that the simple conception of a vein traversing other rocks, and filled with valuable minerals, is by no means the universal form. Indeed the number of such simple veins of sufficiently high grade to be economically worked is limited, and the tendency of modern mining is to take increasing account of the possibilities of exploiting larger masses of low-grade ores which possess few of the characteristics of the type commonly known as lodes and veins. It is necessary, however, to consider this type, since it has always been the most conspicuous, and has constituted the fundamental form out of which the basal mining law of America has grown. I limit this to American law for the reason that it proceeded from geological assumptions which did not trouble the lawmakers in other countries where the rights of the miner were confined within vertical planes extended downward through the superficial boundaries of the property. The American law proceeded from the relatively simple conception of a vein as a recognizable deposit in a fissure or narrow zone, which the miner owning the apex was entitled to follow wherever it might lead, though it should extend beyond the limits of the claim. Such veins were the predominant type that attracted the attention of the early miners in the West. They are characteristic of the Mother Lode in California, and the experience of the Californian and Nevadan miners was largely responsible for the adoption of the principle of the extralateral right. In order to explain this type it is necessary to consider the origin and characteristics of lodes and veins. It must be understood in the

beginning that, so far as we know, such phenomena are confined to the upper shell of the earth. This is because the upper portion of the earth, being free from the high pressures existing at greater depths, is more susceptible to fracture, and the fractures formed remain as lines of weakness. At considerable depths fractures would heal under compression, and be no longer distinguishable, and at very great depths fracturing is inconceivable. The material of the earth would there behave precisely as a plastic mass, and could be squeezed, but not broken, like lead under pressure. But the movements of the earth cause dislocations and fissures near the surface. The rigidity of the outer shell of the earth is not great. In fact the rigidity of the highly compressed mass at the centre is six times less than steel. The earth is constantly subject to varying stresses tending to deform it. These are partly induced by astronomical bodies, and are partly due to contraction resulting from the loss of heat. The contraction has taken place through distortion of the outer envelope, great segments becoming depressed, forming the basins occupied by oceans, while the continents represent minor segments thrown up in an effort to relieve the strain. In addition to these movements on a grand scale there has been a localizing of the movements at certain places where the deformation has become excessive, producing mountain ranges, where the inner mass of the earth has invaded the upper layers. Here the movements have become exceedingly complex, and relatively violent, so that fracturing has been almost universal. Not only have there been elevations and foldings of the superincumbent strata, but lateral pressure, producing a most complicated network of fissures. Great fissures have been formed, but these are invariably accompanied by infinite minor breaks, traversing the rocks in many directions.

To what extent fissures thus formed may remain open until filled by deposits from mineral-bearing solutions depends upon depth below the surface. The pressure increases with such rapidity that it is doubtful whether fissures which can remain open are possible as deep as 5000 ft., and except for vugs, which are open spaces of such shape that arch action may come into play to support the pressures, and prevent collapse, open rents have not been found in mining operations except within a few hundred feet of the surface. The method by which veins are formed along fissures is, accordingly, not the simple one of crystallization of mineral salts out of solution. The deposition is generally a result of chemical interchange between the substances conveyed in solution or in gaseous emanations, and the material composing the permeable zone, which, by a continuation of this process, becomes a vein, a lode, or a metalliferous mass. Such chemical interchange is known in geology as metasomatosis.

If two rocks are rubbed together abrasion occurs; if the pressure is great enough while this movement is taking place, portions of the rock near to the two opposing surfaces become crushed, and the original structure is destroyed. The rock may become disintegrated and partly broken into fragments, called breccia. This is what frequently follows from those movements of the earth which produce fracturing and faulting of the rocks. After such a process of disintegration the crushed portion of the rock is usually more permeable, and it is also in a state admitting more readily of chemical interchange. If you wish to dissolve a lump of salt it can be more promptly done by first reducing the salt to a powder. If a lump of salt be pulverized and a solution of silver nitrate be poured upon it the salt rapidly passes into solution, and as it does so it reacts with the silver nitrate. The result is that the silver unites with the chlorine of the salt, forming silver chloride which deposits as a solid precipitate, while the sodium of the salt unites with the nitric acid of the silver nitrate and passes into the solution as sodium nitrate. This will illustrate the process of chemical interchange, which in a much more complex manner leads to a solution of rock with a corresponding deposition of other chemical compounds which crystallize and fill the permeable zone with a new set of substances, thus forming a lode or vein. It is now plain why deposits of minerals tend to follow the zones of faulting, crushing, and brecciation, and why such phenomena are more frequent in regions which have been subjected to volcanic action. In volcanic action are found the forces that produce the dislocations of the rocks preparing favorable receptacles for veins, and it is accompanied with the emission of mineral-bearing solutions and gaseous emanations which bring in the substances that yield valuable deposits for the miner.

It is also to be noted that the invasion of magmas from below commonly starts with an uplifting of the superincumbent rocks, so that extensive fissuring precedes the actual eruption, and the final outflow of lavas occurs along some of these lines of weakness. Hence the lava is quite likely to open a fissure where crushing had taken place, and it will cool in contact with the walls of rock which are in a favorable condition for chemical interchange. As the lava cools it contracts, and shrinks away from the walls, thus admitting of greater permeability along the line of contact between the two. This reveals why so many deposits are found in contact with, or closely associated with volcanic rocks.

It must be further explained that when such chemical interchange is effected the result will be one of three kinds; either no change of volume follows, in which case the line of weakness is healed and rendered dense, and further flow of solutions practically ceases; or the change is accompanied by a loss of volume; it produces expansion. Where loss of volume occurs the permeability of the zone is maintained, and prolonged mineralizing action may go on; where there is increase of volume pressure is exerted by the altered mass against its enclosing rocks, and this usually causes extensive fracturing and crushing of the new mass which may lead to its further alteration and to successive periods of deposition of minerals. Furthermore, a vein is frequently less resistant to pressure than the unaltered bounding rocks, and hence later volcanic action is likely to re-open such fissures, so that a lode once formed is quite likely to be faulted and brecciated subsequently, when a new cycle of mineralization will be

inaugurated. After volcanic disturbances have ceased a set of complicated movements generally follows, due in part to re-adjustment of the dislocated rocks until equilibrium has become re-established, and also the shrinkage of the crystalline volcanics on cooling induces a settling and re-adjustment of the superincumbent and surrounding rocks. A region once disturbed is subject to a prolonged series of movements, favorable to the formation of suitable zones for the mineralizing action of solutions and gases, and these zones are more abundant and more complicated near the surface than at greater depths. Simplification and narrowing of fissures in depth is a matter of common observation in almost every mining district. It is particularly in evidence in the desert regions, and is characteristic of the famous deposits at Goldfield, Nevada. There the mineralized zones are extremely irregular in shape and width, but become less complex farther down. Moreover their erratic shape renders inapplicable the term lode, so that the United States Geological Survey has adopted the name of reef for these occurrences.

A distinction must be drawn between a lode and a vein. A lode is a mineralized zone of a somewhat tabular form. It possesses a longitudinal extension which is large compared with its width, and its lateral boundaries are approximately parallel. It may or may not have clearly defined walls. The mineralized zone may grade into unaltered rock on either side, but the body of the lode is an altered mass readily distinguishable by its mineralogic differentiation from the bounding country rock. An economic distinction between a lode and a vein can not be made in these days when the tendency is to exploit low-grade ores. Usually a lode is a mineralized zone of relatively low concentration of valuable minerals.

A vein is properly a mineralized zone with sharply defined walls. It need not be economically valuable, but its differentiation from the enclosing rocks is essentially more clear and unmistakable. A vein may exist within a lode, or it may be held between walls of rock which have undergone little or no alteration. A great many veins are associated with relatively wide zones of altered rocks. The whole mass then becomes a lode, within which is included the vein. The two are in reality only different phases of the same geological phenomenon. They grade into each other, and often no discrimination between them is possible. It would be as well perhaps to frankly accept the lawyer's propensity to classify as veins those deposits which have well defined walls. The reason why some sort of distinction seems necessitated is that a lode may contain many veins, the apexes of which may constitute valid bases for the location of independent mining claims. Lodes are often of such great width that it would be quite impossible to establish legal rights within the narrow limits of a claim. An essential feature of a United States mining claim is the grant of the extralateral right. This permits an owner of such a claim to invade the property of another in following his deposit. In order to validate this extraordinary right he must be able to clearly distinguish the lateral limits of his deposit. The importance of the walls then becomes paramount. Whether we choose to call the deposit which he follows a lode or a vein, it must be set off from the enclosing rocks by recognizable boundaries, the ideal form of which would be plane surfaces. Actually the plane surface is the exception, but a clear change in mineralogic character between the deposit and the adjacent rocks is an essential legal requirement. This was reiterated in unmistakable language in a recent decision (Golden v. Murphy (Nev.) 103 Pac. 394, July, 1909) where the court held, "where one claims extralateral rights under the Acts of Congress, because of a vein existing and appearing in his ground but which has no well defined boundaries, and when his claim is controverted, he must, in order to exercise such rights, show a ledge or body of mineral-bearing rock of such value as will distinguish it from the country rock or from the general mass of the mountain. The material must in texture and value be such as to show the existence of a vein, and proof of the fact that the rock is broken, shattered, and fissured, and mixed with calcareous substance, though it may show a conglomerate mass, does not establish within the meaning of the statute a vein. But when the walls or boundaries are well defined, the vein differentiated from the adjacent country, and the kind of materials mentioned constitute the filling, then evidence of slight value in mineral will be sufficient. What constitutes a discovery that will validate a location is a very different thing from what constitutes an apex to which attaches the statutory right to invade the possession of and appropriate the property which is presumed to belong to an adjoining owner. The question of a sufficient discovery of a vein, or the validity of a notice of location, is substantially different from one relating to the continuity of a vein on its dip from the apex, and which tests the rights of the undisputed owner of the surface to what lies underneath and within his own boundaries."

The foregoing clearly states the need of having recognizable bounding walls, and it also affirms the economic requirement of value. The latter is fundamental in the eye of the law, and yet it is uncertain and evasive. A vein may contain valuable substances, but because of its leanness, or its narrowness, it may not be possible to operate it commercially at a profit. The geologist recognizes no economic limitations. He depends upon composition and structure only. He defines a vein by its characteristics as a natural phenomenon. As geologic knowledge enlarges the significance of what may commercially be an unimportant vein so far as exposed may become important as an indication of probabilities which can be verified only by exploratory work. Reasoning from geologic premises a man may conform to the legal requirements of ordinary prudence in undertaking operations for the development of a vein which at the apex may have no value in a commercial sense.

In the end all things in which man can obtain property right, and which may become the subject of litigation, are what the courts define them to be. The geologist is thus forced to employ terms in such a sense as will not be in conflict with their legal in-

terpretation. On the other hand the jurist must depend upon those whose business it is to study the special facts adjudicated, for guidance in making correct distinctions. As at present employed there is lack of agreement concerning the use of the word 'lode'. We speak of lode-claims when in fact we should call them vein-claims, for the reason that a lode may be so immense in size as to be wholly incapable of inclusion within the lateral boundaries of one or many mining claims. To give an example, let us assume that a crushed zone is 900 ft. wide, which is by no means exceptional. If it have fairly well defined lateral boundaries which are approximately parallel, and if the material within these boundaries is mineralized, this mass would conform to the definition of a lode, but it is clear that on such a lode as many as three parallel mining claims could be located, none of which would have more than one wall, and one could show none at all. If the material of the lode were homogeneous it is manifest that the middle claim would lack the essentials for validating an extralateral right. I am not here to argue against the so-called 'law of the apex', but it is worth while in passing to point out the difficulties in according justice under the terms of the statute which has established this principle. It fails even in the case of the very natural phenomenon which has given the name of lode-claim to these possessory rights. In the cases of large irregular masses, and of the broad extensions of disseminated copper ores to which reference was previously made, the application of the law of the apex is manifestly absurd, and yet such deposits are in no sense capable of being held under placer locations. The geologic conception upon which the law was framed was a narrow and imperfect one, which does not square with the facts.

The law states that an owner of a claim may follow the vein on all its dips, angles, and spurs. No difficulty arises in relation to dips and angles. A vein following fracture lines may reverse its dip without losing continuity. It may vary in its course or strike, by making sharp angles, but these vagaries are easily harmonized with rights conceded by a mining claim. A difficulty is introduced, however, by spurs. These may be of two kinds. A spur is a branch. It may lead off from the vein, vertically, horizontally, or at any angle between these extremes. From the explanation given of fracturing, fissuring, and faulting, it will be understood how complicated the associated fracture-lines may become. The peculiar form of the veins at Leadville compelled the adoption of a local rule whereby in that district extralateral rights are by common consent discarded, and compromise has become the resort in many other camps. The essential inadequacy of the apex law is thus brought into prominence. In limestone regions the difficulty is also great. Limestone is readily soluble, and hence ore deposits form with special facility along the contacts of limestone with other rocks, and along the joint-planes, bedding planes, and other fissures. Furthermore the tendency of limestone is to dissolve more readily at some places than at others, so that the deposits widen into masses of extremely irregular shape, and all semblance of well defined walls is lost. Here the law of the apex breaks down utterly. The zinc-lead deposits of the Joplin district, in Missouri, are an example of the erratic type to which I have called attention. Fortunately these occur in a region originally occupied for agricultural purposes, so that the common law principle is there in force, which reduces the rights of owners to a simple determination by surveys. Another instance of orebodies which have occurred without regard to the principle of lodes or veins is afforded by the copper deposits at the Copper Queen mines, at Bisbee, Arizona. Here great masses of rich ore are found in blocks disseminated through a large area. These blocks are often entirely separate from each other, with no connecting veinlets or other leaders. In order to find them the whole mass of rock has to be cross-cut at such frequent intervals as to avoid the possibility of missing them. Deposits of this character are in absolute defiance of the simple conception of a vein which can be followed on its dip downward into the earth.

The mineral deposits which we have been considering have been formed in one of three ways, or by a combination of them, namely, (1) By deposition from solution as a result of crystallization from such solutions or by chemical replacement of the original rocks by matter brought in dissolved in the solution. (2) By chemical interchange in the presence of gaseous emanations bringing metallic compounds in a volatile state, a characteristic of nearly all tin deposits. (3) By actual intrusion of mineral-bearing volcanic rocks, which may or may not require further concentration by solution and re-deposition within the intruded mass. It has been seen that these deposits may possess any shape, and be of extremely variable magnitude. Also it is noteworthy that the enrichment may not be uniform—in fact it rarely is—and the enriched mass may become progressively leaner away from some central zone of higher metallic concentration, forming what are known as stockwerks.

It is now needful to consider an entirely different class of deposit, known as placers. It is evident that the law does in this case proceed from a consideration of origins, confused again by narrow geologic conceptions. The world waits for a definition of 'placer' that will hold in law. In view of the divergent opinions and rulings I might be justified in calling a placer deposit one that can be located under the mining law with the consent of the Department of the Interior as a claim carrying with it no extralateral rights. The original intention was to give mining rights in a deposit laid down superficially, as a gold-bearing gravel bed, to which the Spanish word 'placer' was applied. From deposits formed by sub-aerial agencies, through the wearing away of rocks and veins, and the concentration by streams of the heavy metallic or metalliferous substances, the extension of the idea to deposits thrown down by precipitation from the waters of lakes and oceans was natural. Thus salt, gypsum, soda, and borax, conform to the notion of superficial accumulations of valuable minerals. Such deposits may be buried subsequently by the formation of sedimentary rocks above them, or by lava flows. The rich gold

gravels of certain Miocene rivers in California were deeply covered by great deposits of volcanic tuffs, followed by lava-capping, but because of their origin they remain placers none the less. A buried placer may be included in foldings and dislocations of the rocks during later mountain-making epochs, and may be left standing in tiled positions bearing a resemblance to lodes and veins, without alteration of its character. It still remains a placer, because of its geologic origin. It is indubitable that the intent of the law was to grant claims to deposits of such origin lying horizontally, but horizontally is never more than approximate, and as between an inclination of five degrees, or forty-five, or even ninety, a distinction would be merely arbitrary, and without real justification. The law has, however, made a point of position. A lode-claim will not be given patent unless it goes downward into the earth. This would, apparently, leave a so-called 'blanket' vein, when found in a horizontal position, subject to valid location as a placer. Evidently the only way to reach some of these cases is by special legislation, as has been done in regard to coal beds which, on the ground of origin, would clearly fall under the head of placers, being formed by superficial accumulations of vegetable matter. By what stretch of imagination petroleum deposits were ever classified as placers is hard to see. They certainly do not represent original deposits laid down on the surface or precipitated from surface waters. They are mainly due to complicated chemical reactions altering organic matter in sandstones, shales, and some limestones, into a substance having not the remotest resemblance to the original material acted upon. To some extent petroleum may in a few cases have been derived from reactions occurring in volcanic magmas. In any case it has not been formed directly in the exact spot where found, but has been concentrated into pools and porous layers of rocks by seepage, and it may often have been gathered from beds of great thickness. Moreover, the exact amount so concentrated in any area can not be known, nor can the owner of any portion of the earth's surface be limited to the extraction of that which lies under his claim, since he may drain neighboring ground, or lose what might have laid under it by drainage to adjacent wells. These peculiarities have been met in States where the land was already owned in fee, by the introduction of a leasing system, paying royalty on the amount actually extracted. The adoption of a similar procedure by the Government as applicable to oil on the public lands would seem almost necessitated as a matter of equity.

An interesting case under the placer laws has arisen in connection with the phosphate deposits of Idaho and Utah. These occur in rocks of pelagic origin, and the phosphate was formed by the secretions of animal life. The deposits accordingly conform, on the basis of origins, to the geologic conception of placers. But as originally laid down they were of such feeble concentration as to be of no commercial importance. Subsequently, however, the percolating solutions dissolved and reprecipitated the phosphate of lime in enriched layers. This action is precisely similar to that which has produced many metalliferous deposits where the disseminated metals have been gathered into veins by leaching and subsequent precipitation in favorable channels. In this view there is no sharp distinction possible between these phosphate beds and some veins of gold, lead, or zinc, and they should consequently be capable of valid location as lode-claims. It happens, however, that these beds, lying conformably with other sedimentary rocks, folded into gentle flexures, would enable a lode-claimant to control miles of the deposit by virtue of the extralateral right, thus favoring monopoly on a large scale. The Department of the Interior has in consequence withdrawn these deposits from location pending Congressional action, which is clearly needed in order to deal justly with the situation.

The brief discussion given of the salient features of mineral deposits indicates that the mining law as it now stands was based upon ideas of geologic characteristics that were too simple to cover the facts as they are found in nature. Great deposits of ores of iron, gold, lead, copper, and other metals vary so widely from the form of a lode as conceived for the purposes of a lode-claim as to render the law inapplicable to them except by distorting it from the original intent of its framers. The extralateral right demands, as a condition precedent to its equitable concession, a form and limitation in width of deposit which does not exist in a vast number of cases. The placer claim is made to include deposits which are not placers in the true sense of the word. The multiplication of special acts of Congress only leads to complexity, which to a large extent would have for its sole purpose the rectification of difficulties brought about by the injection of the principle of the extralateral right into our legal system. While admitting the essential reasonableness of the law of the apex in many cases, it is an inevitable conclusion that the ends of justice would be subserved by a return to the ancient usage of the common law in real property as applied to mines of all classes.

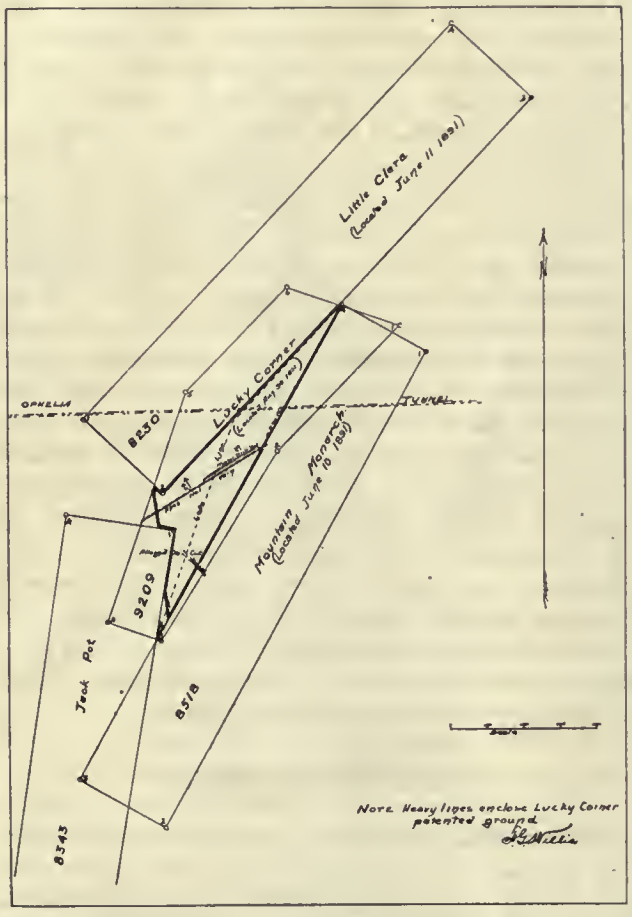
ANALYSIS OF ROCKS

The chemical work of the United States Geological Survey has long commanded the general attention, and many of the reports of the Survey's chemists have become reference works in colleges and universities. One of the Survey's chemical bulletins (Bulletin 305), on the analysis of silicate and carbonate rocks, by W. F. Hillebrand, has been translated and re-published in Germany, and the home and foreign demand for it has completely exhausted the edition printed. A new and revised edition of this manual, numbered Bulletin 422, has, therefore, just been published. Mr. Hillebrand, the author, was for 28 years one of the Survey's chemists and is now chief chemist of the Bureau of Standards of the Department of Commerce and Labor. The two classes of rocks considered form the bulk of the earth's crust, and although the bulletin was not prepared primarily for economic purposes, the methods and principles described may be applied directly to economic work. The rocks of these two classes contain many valuable metals and minerals.

Extralateral Rights Again

Written for the MINING AND SCIENTIFIC PRESS
By HORACE V. WINCHELL

Some new phases of our national mining law were developed in an interesting lawsuit in the Federal Court at Denver recently. The plaintiff company is the Doctor-Jack Pot; owner of the Lucky Corner, a fractional lode-claim patented more than five years ago. The defendant corporation is the Work Mining & Milling Co., owning the Little Clara lode-claim, patented and contiguous to the Lucky Corner on the west. The claims are at Cripple Creek, Colorado. The Lucky Corner is junior in date of location and patent to the claims lying both east and west and as patented is approximately diamond-shaped. Its located end-lines are parallel by virtue



of location corners upon patented ground. Its side-lines are not parallel either as located or as patented. If the discovery vein therefore crosses both side-lines, the claim has no extralateral rights. The relation of the claims is shown in the accompanying figure, furnished by the courtesy of Hills & Willis, of Cripple Creek.

The suit was brought by the owners of the Lucky Corner claim for the purpose of establishing extralateral rights upon two veins alleged to be not the discovery vein, and hence secondary veins apexing in the Lucky Corner and dipping into the Little Clara. Judgment was also sought in large amount for ore extracted beneath the surface of the Little Clara by the defendant company, where, as a matter of fact, the ore was first discovered. Up to this point the case is not out of the ordinary. The novelty arises from the fact that the plaintiff made no attempt to prove a discovery vein in the Lucky Corner, nor to prove that the said discovery vein crosses either end-line of the claim as located. Relying solely upon the presumption in law that a patented claim has a valid discovery, the plaintiff asked the court to rule that it is also to be presumed that the course of the apex of the presumed discovery vein is parallel to the longer lines of the claim, so that if followed it would cross one end-line; and therefore in the absence of conclusive affirmative proof to the contrary the claim has extralateral rights upon all secondary veins within the planes of the located end-lines. Such a ruling would throw the burden of proof as to the course of the primary or discovery vein in the plaintiff's ground upon the defendant instead of making it part of the plaintiff's case to show clearly by what right he seeks to recover damages for ore extracted from beneath the surface of adjoining property.

In the case at hand the situation was still further complicated by the fact brought out in the testimony that the Lucky Corner claim never had a valid discovery; that it lies almost wholly in a gulch and that the discovery workings are in loose gravel. How then could anyone prove that a discovery vein which does not and never did exist crosses the side-lines of the claim? In what direction then are the extralateral rights of a claim which has no discovery vein? Shall such a claim, entered and acquired by fraudulent misrepresentation, be given actually greater rights beneath the surface of adjacent locators than the same claim legally and properly provided with a discovery vein crossing both side-lines? If such be the case the field is open for a vast amount of mining litigation and the dishonest locator will be aided by the law in despoiling his more conscientious neighbor. Moreover, the innocent man will be placed in a position where he cannot possibly protect himself. He has no way of adversing or protesting in the Land Office prior to patent; and subsequent to patent he is bound by a presumption to overthrow which he must trespass upon his neighbor's premises and then only to discover that he is seeking to develop the position of a vein which does not exist.

We shall look with much interest for decisions of the higher courts from which it may be possible to determine: (1) Is a patent conclusive proof not only of a valid discovery vein, but also as to the relation of its apex to the location boundaries of the claim? (2) Is it incumbent upon the party asserting extralateral rights to prove them clearly, or must the defendant do more than exhibit his own patent (senior in this case) or lose through no fault of his own?

Whichever way the matter is finally decided we have another beautiful example of the absurdities and inconsistencies of our mining law as it works out in actual practice. This situation is almost as involved as the Drum Lummon case in Montana, where there have already been decisions of the higher courts so learned and luminous that about a week's time was consumed in the hearing upon the third amended and supplemental complaint as to what these opinions actually do mean.

Cement v. Bone-Ash Cupels

Written for the MINING AND SCIENTIFIC PRESS
By J. W. MERRITT

The relatively high price of bone-ash and the fragility of bone-ash cupels used in assaying has led to the substitution in some places of portland cement. In a description of laboratory equipment and methods of the Provincial Assay Office printed in the twelfth report of the Bureau of Mines, Ontario, 1903, is to be found the following statement: "Cupels made of portland cement have been found by practice to be as satisfactory as bone-ash for the elimination of zinc, lead, copper, arsenic, etc., from gold and silver. The cement cupels have the advantage of hardness and durability and cost practically nothing, as cement is $2 per barrel." This led me to experiment with bone-ash and cement cupels under the same conditions in order to ascertain their relative merits.

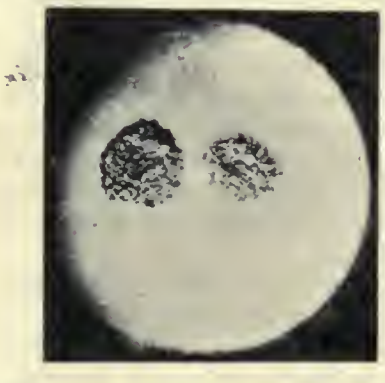
Bone-ash cupels were made in hand-molds in the usual way and allowed to dry for three weeks. Cement cupels were made in five grades, varying in wetness from a shade less than that of bone-ash to a consistence which made the cupel stick to the plunger of the mold. These cupels were allowed to dry for five weeks, when they were found to be in the following condition: The driest were slightly harder than the bone-ash cupels. Those made the same as the bone-ash were found to be so hard that they would just break when allowed to fall five or six feet on a hardwood floor. Those made up wetter than the bone-ash were found to be too impervious and were undesirable. Two tests were made with these cupels, as follows:

First test: Ten cupels, five bone-ash and five cement, were arranged alternately in two rows across the muffle. When hot, the lead buttons were placed in them for cupellation. In each button was a weighed amount of silver (averaging a little over 10 mg.) plus the silver in the test lead. These buttons were obtained by scorifying test lead with a known amount of silver, and weighed about 15 grams. The muffle was kept at an orange heat. Cupellation progressed uniformly and all the cupels were withdrawn at the same time. The average loss of silver in the bone-ash cupel was 6.38%. For the cement cupel it was 6.64%.

Second test: The cupels were arranged as in test No. 1. The furnace was run with the muffle at light cherry heat. The silver was this time wrapped in sheet lead. Weights of silver were same as in test No. 1. The cupels were all ready to be withdrawn at the same time. The average loss for the bone-ash cupel was 4.62% and for the cement cupel was 4.91 per cent.

Two essential points of difference between the bead from the bone-ash cupel and that from the cement may be noted. First, the bead from the bone-ash cupel stood up good and round, on a small base, while that from the cement was flat and stood on a base which was as wide as the broadest diameter of the bead. Suspecting lead in the latter, it was tested, but no lead was found. Second, considerable cement clung to the bead after brushing, while very little bone-ash clung to the bead from the bone-ash cupel. The accompanying photomicrograph shows the bottoms of the two beads, magnified about 12 diameters. The larger, darker one is the bead taken from a cement cupel, and shows a large amount of cement clinging to the bead. These beads appear to be of different size, but this seeming difference is due to the fact that the bottom of one of the beads is smaller than that of the other, and only the bottom of each is in focus. The upper surface of the bead from the cement cupel appeared to be slightly rougher than that of the bead from the bone-ash, and of a duller color, but little sign of sprouting was apparent on either.

The advantages of the cement cupels are hardness



Photomicrograph of Bottom of Assay Buttons.

and durability, convenience—in that the cement can be more easily obtained in the field than can bone-ash—and cheapness. Cement can be bought by the barrel at from 35c. to 40c. per 100 lb. Bone-ash can be bought at about $5 per 100 lb. If an assayer should use say 140 cupels per day, estimating that these cupels would run 14 to the pound with bone-ash at about the same weight as cement, he would use 50c. worth of bone-ash, or 4c. worth of cement per day. On the other hand, the difficulty of the cement clinging to the bead when weighing, and the fact that silica remains insoluble in gelatinous form while parting, which would vitiate the results on gold, balanced against the fact that little bone-ash clings to the bead and that only a very small percentage of the bone-ash is insoluble, makes the use of cement cupels unsafe in work where accuracy is desirable. For specimen assays, cement cupels might be used with profit. Cupels of cement, with a top coating of bone-ash, have been suggested, and experiments along this line would be interesting. The above tests were made in the Metallurgical Laboratory of Northwestern University, under the direction of W. H. Coghill.

An investigation of the Estancia valley, in the central part of New Mexico, was made last summer by O. E. Meinzer, of the United States Geological Survey, for the purpose of ascertaining the possibility of utilizing its ground water for irrigation. This broad valley, which contains extensive tracts of tillable land, is bordered by mountains, hills, and mesas and lies at the centre of an inclosed drainage basin that covers about 2000 square miles.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Engineer and His Report

The Editor:

Sir—Often the reputation of the engineer who signs a report is more valuable to the promoter who has mining stock to sell or the original mine owner who has a mine to sell, than the actual work performed in examining a mine or making a metallurgical test. In fact, the mining engineer who has spent perhaps 15 to 30 years in the business and has built up a reputation for honesty and ability, considers his reputation as so much capital which he naturally wants to protect. Anyone in business would want to protect his business and can do so, but not always the engineer his reputation. To illustrate, I will give some of my own personal experiences, and there may be similar cases which have never been brought to my attention.

About nine years ago I took an interest in the Val Verde smelter, near Prescott, Arizona. This plant was afterward sold to the Bradshaw Mountain Copper Mining & Smelting Co., and destroyed by fire. In addition to a salary under contract, our company had made a contract with the Standard Smelting & Refining Co. to smelt their ore and concentrate. There was nothing objectionable in this, if they had any ore to smelt, but a few months later a friend of mine in New York wrote me inquiring about the Standard Smelting & Refining Co. (one of the side companies of the Douglas-Lacy Co.), asking what I knew about it, as I was considered to be with the company. This I denied, when, in reply, one of Douglas Lacy's circular letters was sent to me, headed, 'Second Edition, September 16'. In it my name was used in such a way as to lead stockholders to believe that I would be one of the company, and partly responsible for its success. In addition to this letter, I understand there were others which I never saw. I immediately took the matter up with one of the best lawyers in Prescott, Arizona, who informed me that it would be useless to fight such a combination of people.

Later, since I came to California, a sample of oxidized ore was once sent me, low in silica, rich in bismuth and gold, and containing considerable lead and silver. The man sending this sample asked me to have it assayed, and stated that the owners were having a concentrating plant put in. He asked me what I thought about it. I sent him the assays and stated that I sincerely hoped, if the owners were friends of his, that they would not attempt wet-concentration of the ore. I did not charge a cent for the assays or my comments. This correspondence took place about three years ago. Last November, when I was in Sinaloa, Mexico, on other business, I found this property, the Amazon, shut down, and sold for taxes. There was a very nice little concentrating plant, and a few tons of concentrate on the ground. This was not much of a surprise to me, but the contents of a circular letter which was handed me was. I herewith quote that portion which refers to me, and which would lead people to believe that I was responsible for the process the Amazon company had adopted: "During the first visit of Mr. Craibs to the mine, he made a change in the management, employed an expert, Mr. Edwards, for consultation regarding the bismuth, and has also placed this problem before the Hendley people, the Allis-Chalmers people, and finally before Mr. S. E. Bretherton, one of the greatest smelter men in the world, now the general superintendent of the Great Western Gold Co., and together they have arrived at a method of treatment which all of these men pronounce successful."

My name may have helped to sell stock but using it in such a connection was certainly a great injury to me. Such language as the above may please boys, but not men of experience whom it injures and yet, what recourse have we?

S. E. BRETHERTON.

San Francisco, April 23.

Coal-land Prices

The Editor:

Sir—Your editorial defense of the new valuation of coal-lands by the United States Geological Survey, under date of April 2, 1910, has been read with interest, yet fails to convince me that there is anything in its favor except that the new price will ultimately net the Federal Government about $700,000,000 more for the coal lands yet in Federal control in the public lands States than the price heretofore charged for these lands. In defending this increase you have undertaken to weave in other and entirely extraneous matters by citing that under the new rates the Federal Government will not sell the land until there is a real demand for the coal, which has nothing to do with the new prices but is rather a matter of terms which will be decided by Congress and not by the Geological Survey. The confusing and wholly unwarranted statement that because the purchase is made long prior to the date of production the ultimate price for coal would be higher under the present prices than if the higher price prevails, is not a matter of fact when we consider that the higher first cost of the land will prevent small operators from engaging in the business, that if all the land is re-appraised at the same rate as that already gone over the purchase price will be 200% above what it is now, competition is destroyed by elimination of the small operator, title to a greater proportion of the land remains in the Federal Government, non-taxable, and the rate will be higher on the privately owned coal in consequence. The greatest danger to the consumer and the most certain result if the Government "holds the coal lands, parting with them only as the coal is actually needed," would be that mining companies would put a higher price on the coal. The safeguard against exorbitant prices in the East is the sharp competition between producers. The whole fabric of your argument favoring higher prices for the coal lands fails when the price of the land is considered independently, and all other features are as applicable to the lower as to

the higher per acre price. The proposed higher price is in the interest of monopoly, is the opposite of conservation, and has for its only excuse a desire to get better prices for the land. The members of the Spokane branch of the American Mining Congress are not opposed to State control, title to remain in the State, to the end that all revenues from leases may return indirectly to the people in the localities where the coal is, and the selling price can be controlled by the State.

Under the Constitution, the Federal Government is not empowered to rent or lease anything, and under section 8 of article 1 of the Constitution are these words: "The Congress shall have power to lay and collect taxes, duties, imposts and excises, to pay debts and provide for the common defense and general welfare of the United States; but all duties, imposts and excises shall be uniform throughout the United States." To which the United States court adds (157, U. S. 557). "Thus in the matter of taxation the Constitution recognizes the two great classes of direct and indirect taxes, and lays down two rules by which their imposition must be governed, namely, the rule of apportionment as to direct taxes and the rule of uniformity as to duties, imposts and excises." And the same court in another case (157 U. S. 429, 557) states: "Although there have been from time to time intimations that there might be some tax which was not a direct tax, nor included in the words 'duties, imposts and excises', such tax for more than 100 years of national existence has yet remained undiscovered, notwithstanding the stress of particular circumstances has invited thorough investigation into sources of revenue."

There seems in your article to be a confusion of law and suggestion as there is in many articles favoring changes in the method of disposal or non-disposal of our resources and utilities. In fact prices of coal lands have not yet been raised but it is suggested to raise them. Even much of the proposed legislation as to Federal control would not bear the analytical scrutiny of competent courts of law. The Spokane branch favors conservation which shall reduce the cost to the consumer, make waste places produce something, the power from our water ways take the load off the coal mines, where electric power can be used. This is not encouraged by Federal interference but by wise use under State regulation.

L. K. Armstrong.

Spokane, Washington, April 15.

Cyanide Notes

The Editor:

Sir—In your issue of January 15, Bertram Hunt writes on 'Researches Upon Cripple Creek Telluride Ores', remarking that, "the use of cyanogen bromide ('bromo-cyanide') was strongly advocated at one time, but with the exception of a single mill in Western Australia one does not hear of its being in use." Evidently Mr. Hunt does not follow treatment in this State, or he would not write so. The original mill at Kalgoorlie using bromo, was the Hannans Star, but this is now shut down, as the company is about to consolidate with the Lake View Consols, which has 75 stamps and one No. 5 Krupp ball-mill wet-crushing, concentrating, tube-milling, agitation with BrCy, and filter-pressing at the vats of 11,200 tons per month, with about 90% extraction at a cost of $2.46 per ton. The Oroya Links company has 50 stamps, Wilfley tables, tube-mills, agitation of slime with BrCy, and filter-pressing at the rate of 11,500 tons monthly, with 92% costing $2.44 per ton. In connection with the milling results of these two mines, the former mine is dealing with a hard ore, and the ball-mill has just started, so it must not be taken into account; while in case of the latter mine, the ore is fairly soft. Another mill using BrCy is that of the Golden Horseshoe. Here 150 stamps—soon to be 200—are at work, with Wilfley tables, tube-mills, and grinding pans in series, agitation with BrCy, and filter-pressing. An average of 24,500 tons is treated monthly, and of this quantity about 17,000 tons are treated by this chemical for 90% extraction, costing $2.80 per ton. Finally, we have the Ivanhoe mill with 100 stamps, tables, grinding-pans, sand, and slime treatment. Of the latter product, some 10,000 tons is treated by BrCy, the monthly output being over 19,000 tons. A little under 90% is extracted at a cost of $1.90 per ton. I am not by any means holding forth on the merits of the BrCy process, being firmly wedded to the dry-crushing, roasting, and plain cyaniding for the sulpho-telluride ores of this field; but I simply wish to point out that Mr. Hunt is slightly in error on this point. There is one thing certain about the wet-crushing process here, that, if BrCy were not used, the extraction would be very low. Certain minerals in our ores are soluble in BrCy, but not in plain KCy, that is, in raw treatment. Is not the BrCy process being used on some arsenical ores, with a high percentage of arsenic, at Deloro, in Canada?

In an editorial, in your issue of January 15, you had much to say about the Goldfield Consolidated of Nevada, which must be a wonderful mine. You said: "America can now boast of possessing the premier gold mine of the world, thus wresting first place from the Transvaal." Do you mean as regards the monthly or annual yields, or as to the value of the mine. Mr. Rickard once said that "The value of a mine depends on its present profits and its future development," or words to that effect. Now, a comparison between the Goldfield Consolidated, Homestake, Robinson, and Waihi mines present yield and future prospects, would be highly interesting. Which is the premier mine (gold) of the world? There is one laudable point about your Nevada mine, and that is its detailed monthly tonnage, costs, and mine development. Why don't all your American mines, whether working for precious or base metals, do likewise? We are compelled to in Australia.

M. W. von Bernewitz.

Kalgoorlie, Western Australia, March 12.

[Our note about the Goldfield Consolidated had reference to present annual production. There are of course many bases for such comparisons, and each is, to some extent, unfair to some mine. The Goldfield Con. is setting an excellent example, as Mr. von Bernewitz notes, in the matter of fullness of monthly reports.—Editor.]

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Baguío is a term used in the Philippine Islands for the severe hurricanes which occasionally devastate the region. It is pronounced bah-geé-o.

Tropical wood is not generally good fuel and it requires large fireboxes in boilers to accomplish proper combustion and to keep up a steady steam pressure. It has been observed that it requires unusually large boiler capacity to do a given amount of work. This is in part explained by the great radiation that occurs in the humid atmosphere. For this and other reasons, it is wise to provide ample boiler capacity.

Concrete piles were first made in France by Hennebique in 1896, and were made of the east and driven type. During the following decade this general type was developed by different engineers, and is now more generally used in Europe than any other. In the United States the Gilbreth (patented in 1908), Chenoweth (patented in 1904), and Raymond (patented in 1896), are the best known varieties of cast and driven piles.

Cast and driven piles require careful handling if made in long lengths, as cracks cannot be readily detected, and the piles should preferably be allowed to set several weeks before using. If made on the job this delays the work, while if made in distant yards, the exact lengths are hard to gauge, and the piles may be either too short or too long. As the operations of lengthening or shortening cause delay and expense, it is very desirable that the penetration be determined before the piles are brought to the site.

Waste in the woods, the mill, and the factory in the United States is so great that two-thirds of what was in the tree is lost on the way to the consumer. The heaviest part of this loss takes place in the sawmills. Much of this mill waste is unavoidable under present conditions, but the greater the demand for the product and the higher its value, the better will economy pay. Waste in manufacture is small compared with that at the sawmill. Study of the demands of the wood-using industries may be a means of finding out how the mill may profitably market a part of what now goes to the burner in sawdust, slabs, and trimmings.

Germany's greatest achievement in connection with navigation of the air is not the technical perfection of the air-going craft; she has learned how to use the air currents, as the birds do, in traveling. This is a science; the ship is only its instrument. Airships will double and treble their speed by acting in harmony with the forces of nature, the primal speedmaker. There is a working force only lately reckoned with, even by builders of air craft—and that is the wind. Airships will use the tradewind to reach this continent because it always blows one way. That is as simple a proposition as that a low-powered steamer should use the gulf stream. Air traffic, to compete with rail or water, must maintain as sure a schedule of travel. Germany has already mapped her airship routes to and from America.

Helium is a gas given out by radio-active bodies, and since, except in beryls, it is not found in minerals which do not contain radio-active elements, it is probable that all the helium in these minerals has come from these elements. In the case of a mineral containing uranium, the parent of radium in radio-active equilibrium, with radium and its products, helium will be produced at a definite rate. Helium, however, unlike the radio-active elements, is permanent and accumulates in the mineral; hence if the amount of helium in a sample of rock and the amount produced by the sample in one year be measured, the length of time the helium has been accumulating can be found, and hence the age of the rock.

Wild-catting does not mean in the oil business quite the same thing as in mining. In the latter case there is a stigma of which does not attach to the word when applied to the development of new oil territory. Indeed, among oil men the word 'wild cat' is used much as 'prospect' is among miners. A wild-cat well is one drilled in unproved territory. It may be in a region where every geological condition is favorable; indeed the term is even applied to a well sunk in improved territory between productive pools. Sinking wild-cat wells is an entirely legitimate business, and many men of the highest character are engaged in the business. It does not correspond at all to sinking money in a wild-cat company either for the development of oil, minerals, or transportation.

Prevention of corrosion in iron or steel is based on the use of a practically inhibitive pigment to prevent the inception of corrosion and a second coat to protect the first from atmospheric and temperature conditions and to fill thoroughly any voids. To meet these conditions the pigment should be practically inert and its particles extremely small. While red lead is not absolutely inhibitive, it has been demonstrated to be a first-class pigment for use in the preservative treatment of steel in almost any situation and its particles are extremely minute. It is heavy and settles quickly, necessitating the mixing of a new lot if it has stood any length of time. The settling may be retarded by the use of barytes or asbestine, and the use of the latter is to be recommended by reason of its permitting a firm hold on the pores of the steel. The oil should be pure, as the matter of vehicle is of large importance, and the raw oil is better than the boiled. A mixture of red lead, oil, and asbestine, in the proportions of at least 15 lb. of red lead and 2 lb. of asbestine to a gallon of oil, with sufficient japan dryer to work well, may be recommended. The use over this of a first-class graphite paint will serve thoroughly to protect the shop coat and to fill any voids; the particles of well ground graphite being extremely small.

JOHANNESBURG, TRANSVAAL

New System of Mine Returns. — Profits per Square Fathom. — Utopian Ideas. — Flotation of Government Mining Areas. — Ore Reserves and Gold Recovered.

In a recent letter reference was made to the promised introduction of a new system of mine records, based on some unit of square measurement, as opposed to the normal basis of tonnage milled. Full particulars have been issued and have met with a mixed reception. The scheme is to be adopted forthwith upon the Eckstein mines, in connection with a new form of quarterly returns. To appreciate the purport of the innovation and, at the same time, the weight of the opposition, some explanation of old methods must be made. Monthly records of operations have been made in detail and most companies have kept—and will, no doubt, continue to keep, precise data on the following points: (1) Development footages, and value of all new exposures. (2) Tonnage and value of ore developed thereby. (3) Ore stoped, with figures of fathomage, value, and stope width (measure and calculated) from each place. (4) Ore from development faces. (5) Tons packed underground. (6) Tons hoisted and sorted. (7) Tons milled, with all data relative to metallurgical operations and results.

Every item of cost reasonably required to be segregated is worked out, and for general guidance and for such purposes as the annual reports, the mining costs are shown 'per ton mined' and 'per ton milled', and the treatment cost 'per ton milled' and 'per ton treated'. Now, the argument is that (1) managers are forced owing to the publication of monthly reports to make uneconomical efforts to equalize monthly yields and profits, for fear of a drop or rise being given undue importance, and (2) that the close attention paid to costs per ton milled and the conclusions drawn therefrom as to managerial wastefulness or economy lead to the abuses of excessive stoping widths and inadequate sorting. The force of contention No. 1 is reduced by the fact that in the big mines of today the number of stope-faces kept in operation is necessarily so great as to ensure a fairly regular average, variations in which are met by the maintenance of a gold reserve. As for contention No. 2, it is as easy to attach too much importance to the significance of this as it is to overestimate the significance of a showing on the ton-milled basis. Because some Transvaal papers may proclaim with enthusiasm the reduction of costs on a certain mine to 13s. per ton, regardless of the fact that the company drew 30% of its mill ore from a dump of development rock accumulations, or because 3-ft. stoping with 25% sorting has cost 40% in excess of wide-reef mining, doing 10% sorting, and with its development complete, there is no cause for individual managers to receive unmerited censure or commendation from those whose opinions count. Every system is open to abuses, and no doubt the one of basing costs on the tonnage milled has been manipulated in some cases to serve visionary ends and to gain popular applause. But it would be erroneous to conclude that the great reduction in working costs recorded during the past three years has been the result of manipulation of figures in any but a small degree. When we hear the shriek against the 'bogey of low costs per ton milled', we may generally conclude that somebody has yet to learn the art of economical mine administration, of making good miners, and of keeping them. The new quarterly returns call for the following items, the last being considered to be the crux of the whole scheme and unerring criterion of progress:

1. Area developed on plane of reef in square feet, (a) South Reef, (b) Main Reef Leader, and (c) Main Reef.

1a. Total area in square fathoms.

2. Areas stoped out on plane of reef in square feet, (a) South Reef, (b) Main Reef Leader, and (c) Main Reef.

2a. Total area in square fathoms.

3. Resultant average stoping widths by actual measurement, (a) South Reef, (b) Main Reef Leader, (c) Main Reef, and (d) total.

4. Value of total gold content of areas stoped as disclosed by block assay plan of ore reserves in situ.

5. Average gold content per square fathom stoped = 4 ÷ 2a.

6. Value of total gold won.

7. Average amount of gold won per square fathom = 6 ÷ 2a.

8. Percentage of recovery (100 by 6 ÷ 4).

9. Mine working costs per square fathom over areas stoped on all reefs, in pounds sterling.

10. Proportion of accessory costs chargeable against annual profits per square fathom, including maintenance, profits tax, head office, and everything except increase of capacity of plant.

11. Average working costs per square fathom = 9 + 10.

11a. Total working costs = 11 by 2a.

12. Total distributable profit obtained 6 − 11a.

13. Distributable profit per square fathom stoped 12 ÷ 2a.

There are several commendable principles involved in this scheme, provided the return is solely used for internal use and not issued as a Chinese puzzle for the amusement of shareholders. The dominant influence that it is intended to convey is that of checking careless mining and forcing managers to aim for the maximum profit per unit of area. The best way to ascertain whether unnecessary waste is being sent to the mill for the sake of appearances under the head of 'expenditure per ton milled' is not through the medium of such general returns, however ingenious; for no statistics of so meagre a range as those reproduced above will indicate the measure of increasing or decreasing efficiency. The bare total of profit, not per ton, but per month, is as valuable a guide. It must not be imagined that the manager who, for a couple of years, obtains a good showing in profit per fathom is necessarily doing the best for the whole mine—to be measured in hundreds of acres. Gaining the maximum total ultimate profit should be the aim, and not the greatest profit per claim for a given period; the latter perhaps gained by the operation of the high-grade blocks in a number of scattered workings on an excessive number of levels, or by drawing uneconomical proportions of the ore from each reef. These matters, it may be said, can be regulated by supervision, but so can the abuses of the tonnage-milled system that are declared to necessitate its displacement by something more scientific. If managers are working uneconomically to gain credit under an improper system, it is better for the directors and their technical advisers to get at the actual facts and details of bad practice than to seek cognizance of its influence by inferences from a series of belated and unreliable returns.

The issue of 175,000 shares out of a total capital of 1,400,000 shares, at par value of £1, in the newly floated Government Gold Mining Areas (Modderfontein) Consolidated, Ltd., has proved highly attractive. Barnato Brothers, who have been the successful tenderers for the Government ground, were obliged to offer these shares to the residents of the Transvaal. The applications for shares, limited to a maximum of 400, totaled 6000, equivalent to an amount exceeding £600,000. It has been taken as a foregone conclusion that all shares allotted will bring a certain profit, so that this original scheme by which the Government has presented a bonus to the speculating public has earned high favor. Although regarded as a socialistic precedent, this method of compensating the public for depriving it of rights impossible to grant by pegging, lacks many features of popularity. It has been necessary to accompany all applications for shares with cash in full, which immediately gave favor to the rich man in command of several 'dummies'. Work upon the Modder Consols has already been commenced, thus constituting another centre of activity to call for 6000 natives in the course of a few years. In three years' time, these Far East Rand mines will be requiring 20,000 to 30,000 more boys than they employ today. Labor is a factor in calculations of prospective value with which a doubt as to grade, even of 10 to 20%, appears of minor importance.

The meeting of the Aurora West—a small mine of small interest—was remarkable for the confession or explanation

from the chair that the gold called for by ore reserve valuation was not accounted for by actual operations. There is nearly always a discrepancy upon the Rand between the mine grade as calculated from screen value and from face sampling returns, that averages 10%. The Aurora West discrepancy has been much more serious, and although the payable ore reserve valuation at December 31, 1908, was 8.1 dwt., the yield for 1909 was only 26s. per ton after sorting. The payable ore reserve is now shown at 5.7 dwt. The difference cannot be explained without further details, but the gold occurs in this district largely in a stringer of 'reef' (often only an inch wide), whose true value sampling results are liable to exceed. However, it was most satisfactory to find the chairman of the company enunciating the sound principle that an effort was made to "work the mine on the basis of the average yield to be expected from available data as representing the grade of the property." There appear to be many today who, in the happy pursuit of theoretical gains, are apt to forget this honest principle, upon which the credit of the Rand has been so largely based. The practice of straight driving, below the 'reef', in a mine of such a character as to prevent the reliable valuation and location of stoping blocks without much cross-cutting, has been previously criticised. It is being followed by the Rand Collieries gold mine, which claims the following advantages, while admitting the defect of comparatively inadequate reef disclosures. (a) Cheaper developing costs. (b) The underlying or foot-wall 'reef' is more accessible and may even be exposed. (c) Cheaper mining costs for these reasons, (1) after stoping operations have been commenced it will be an easy matter to keep these levels open, but drive pillars will be unnecessary; (2) less labor required and cheaper and quicker shoveling and tramming; (3) greater facilities for using long-wall system of mining. The question is, whether the company will be able to work conveniently without auxiliary driving along the 'reef'.

LONDON

Globe & Phoenix Attracts Attention. — Salt Union Building New Works at Manchester.—Rio Tinto Annual Report.

Globe & Phoenix, a Rhodesian gold mining company, has been much to the fore in London recently owing to the great increase in the reserve and the content of the ore. The ore reserve at the end of December, 1909, is reported to be 171,507 tons, averaging 31¼ dwt. per ton, with a gross value of £1,124,878, as compared with 144,348 tons, with an average of 16 dwt. and gross value of £485,020 a year ago. The profitable ore extends to a greater length on the fifteenth level than on the fourteenth and thirteenth, the actual lengths being 1923, 1315, and 1230 ft., respectively. Work on the sixteenth level, below the dike, disclosed remarkably rich ore; the south drift is 208 ft. long and assays 37.7 dwt. over 31½ in., and the north 212 ft., assaying 157 dwt. over 32 in. The average of the orebody on the sixteenth level is 64.6 dwt. over 31.8 in., as compared with 28.9 dwt. over 37.9 in. on the fifteenth level. The seventeenth level is opening well, for on the south drift which is in 102 ft. so far, the orebody assays 28.6 dwt. over 30 in. The north drift has not yet been commenced. During the latter half of the year 1909 some of the high-grade ore was sent to the mill, so that the output and profit have been substantially increased. The amount of ore crushed in the 40-stamp mill during 1909 was 74,492 tons and the yield was 59,306 oz. The sand-plant treated 44,268 tons and recovered 4357 oz. while 23,861 tons of accumulated and 4950 tons of current slime yielded 2840 oz. The total production was, therefore, 66,503 oz., or 17.85 dwt. per ton. The working cost, including mine development, was 28s. 2d. per ton, which is an increase of 2s. over 1908, chiefly due to the fact that the machinery is old and has required much expenditure to improve its condition. The total revenue was £283,882, and the expenses and allowance for depreciation £133,236 leaving a profit of £150,646. The year commenced with a balance in hand of £47,802 so that the amount available for distribution was £198,448; out of this £160,000 has been distributed as dividend for 1909, being at the rate of 80% on the capital. The £1 shares now stand in the market at £8. I referred in this column some six months ago to the difficulty of treating this ore by cyanidation owing to the presence of antimony. It is now stated that the new plant for the improved treatment designed by H. T. Brett is being erected and should be at work in May. In the above figures relating to the extraction by the sand-plant it will be seen that the yield was only 2.33 dwt. The assay-value of the charge was 7 dwt. so that 4.67 dwt. was left in the residue. The new plant will not only treat current sand and slime but also the old residue and accumulated slime. At the present time some of the rich reserve is being milled in order to provide funds necessary for the thorough overhauling of the plant.

The Salt Union is by far the largest producer of salt in England. It owns extensive tracts of salt land in Cheshire and is managed in Liverpool. It was formed as an amalgamation of many owners in 1889 at a period when German and American production threatened competition not only in the chemical trade but in the export trade to foreign countries for household uses. The first year of its existence the production of salt was approximately 1⅔ million tons and the net profit was £320,400, out of which debenture interest, 7% on the preference shares and 10% on the ordinary shares, was paid, besides £40,000 being placed to reserve. How the production and profits dropped subsequently may be seen by the gradual fall in the ordinary and preference dividend. The ordinary dividend dropped to 1% in 1896, since which time the only distribution in this class of shares was 1¼% in 1907. The preference shares received their full 7% until 1896, but since then 13 years have provided only 35½%. With regard to the capitalization of the company it must be remembered that some years ago an effort was made to bring it more into line with the decreased value of the properties. Originally there were 200,000 ordinary shares of £10 each and 100,000 preference shares of similar denomination, as well as £1,200,000 in 4½% debentures. The preference were cut down to £6 each and the ordinary to £4 each, and the rate of distribution of late years on the preference shares has been on the reduced capital. The report for the year 1909 shows a production of 774,000 tons as compared with 781,000 in 1908. The net profit was £100,438, out of which £54,000 was paid as debenture interest, £25,000 as a dividend on the preference shares at the rate of 4⅙% and £20,000 placed to reserve. It is stated that there has been a further shrinkage in the amount bought by chemical manufactures, and that the bad fishing season has caused a decrease of the demand from this source. Also competition in the Indian markets has tended to reduce the export price. In order to keep pace with competition, the company is erecting a modern plant at Weston Point on the Manchester Ship Canal, near the present works, the money being provided by the recent sale of surplus lands. This plant will be of the multiple-vacuum type and it will be operated electrically. Improvements have been introduced into the system of purifying the brine for the purpose of producing a better quality of salt that will command a higher price. But with the present economics of the world's industry in salt it cannot be expected that even the best business management and the most modern technical skill can place the Salt Union again in the position it occupied in 1889.

The report for 1909 of the Rio Tinto shows that the great Spanish mine produced during the year 1,788,987 tons of ore, with an average content of 2.349% copper. Of the total 604,799 tons was ore suitable for shipment to chemical manufacturers, and 1,184,188 tons was treated locally in the blast-furnaces and by leaching. The amount of cupriferous ore shipped during the year was 600,946 tons. In addition to which 619,814 tons of washed ore was shipped for its sulphur value only. The copper production at the mine was 24,364 tons, and the content in the shipped ore was 11,008 tons, making a total output of copper during the year of 35,372 tons. The actual sales appearing in the accounts were 35,496 tons. The income and expenditure are not published but the gross profit for 1909 was £1,515,623. After deducting £122,999 for taxes, £81,123 for expenses of administration, allowing £85,269 for depreciation and bring-

ing forward the undistributed balance from last year, a sum of £1,233,995 remains. Out of this £81,250 has been distributed as dividend on the 5% preference shares and £1,125,000 as dividend on the ordinary shares, at the rate of 60%. The par value of the ordinary shares is £5 and on the day when this report was issued they stood at £76 in the market, which means that investors are at present content with 4%. The extensive work in connection with the removal of the overburden from the western portion of the San Dionisio orebody has been prosecuted actively during the year and the amount excavated has been over one million cubic metres. During the current year the top of the orebody should be reached and mining by open-cut commenced. In addition 1,200,000 cubic metres of overburden has been removed from the South Lode, and much more work has to be done here before the normal output is once more reached. Thus operations for open-cast work and the necessary equipment have entailed considerable expenditure, and £300,000 has been allocated for the purpose during 1909. The sums employed in this way are charged to a suspense account, which will be liquidated when the ore is mined. The funds required in the meantime are provided out of the reserve fund. The water supply has given no trouble and the reservoirs, including that recently built, are now full.

BRITISH COLUMBIA

Spring Resumption of Work. — Nelson, Rossland, Ainsworth, Slocan Mines Busy. — Granby.

With the return of spring preparations are being made for a resumption of placer mining. John Hopp, the largest hydraulic operator in Cariboo district, who during the winter has constructed additional dams and other works to increase his water supply, will commence hydraulicking in the vicinity of Barkerville as early as local conditions will allow. John B. Hobson purposes leaving Victoria for Quesnel Forks early in May to resume hydraulicking near Bullion. Howard W. Du Bois, of Philadelphia, is pushing on important work in dam and ditch construction preparatory to placer mining on a large scale in the Quesnel Forka district. J. M. Tuffner, manager for the North Columbia Gold Mining Co., after wintering in Cincinnati, Ohio, has returned to Pine creek, Atlin, where his company has extensive placer properties. Lode mining is being carried on chiefly at Hedley, Similkameen district, and near Nelson. The Hedley Gold Mining Co. is adding plant and machinery at both mines and mill, and is steadily developing. This company made a net profit here of $68,813 from August 13 to December 31, 1909. In Nelson division, the Granite-Poorman mines and mill are being regularly operated. Another gold-milling operation in Nelson division that has attracted attention is the Nugget Gold Mines, Ltd. Last year'a profit was $49,698, which brought the credit balance up to $66,349. A large permanent stamp-mill and plant is contemplated. Several other companies in Ymir, Salmo, and Erie camps of Nelson division are also producers, the most important being the Yankee Girl, near Ymir. The Silver King mine, near Nelson, has this year shipped in excess of 1000 tons of silver-copper ore, running about 20 oz. silver per ton and 4% copper, while the Emerald, in Salmo camp, has sent out a similar quantity of ore containing 40 to 50% lead and a little silver. At Rossland the only important recent development is the discovery in the Consolidated M. & S. Co.'s War Eagle of another large shoot of ore containing a much higher average amount of gold than is general. Diamond-drilling is being continued in the Le Roi, but without favorable results. Le Roi No. 2, Ltd., during the four months of the present year has shipped to Trail rather more than 10,000 tons and milled approximately 5000 tons.

Ainsworth and Slocan districts are making good showings The recent suspension at the Blue Bell, in Ainsworth division, is a set-back especially since there is a large quantity of lead-zinc ore available. It is stated that hoisting and pumping machinery must be provided before the large reserves of ore can be utilized. Melting snow will for several weeks interfere with shipment of ores from Ainsworth and Slocan mines, but several are in better condition for the production of ore than for some time past. The return of summer will see the Cork, on south fork of Kaslo creek, and the Whitewater group, also in Ainsworth division, resume production. The Lucky Jim mine is again shipping ore, much of which assays about 52% zinc. Its production during seven months of last year was more than 5000 tons. At no previous time for several years has the outlook for the Slocan been so promising as at present. In addition to the Rambler-Cariboo, Ruth-Hope group, Slocan Star, Richmond-Eureka, Standard, and Van Roy, production may be expected from the Surprise and Sunset, near Cody, the Mollie Hughes, at New Denver, and the Eastmont (Ellis Silver Mines, Ltd.), also near Slocan lake. Large orebodies are being developed at the Hewitt-Lorna Doone group, operated by the Silverton Mines, Ltd., of London, but no arrangements have yet been made to stope and ship. Boundary district mines continue productive, ore shipments for this year aggregating about 630,000 tons. Granby is mining and smelting about 25,000 tons per week. Jay P. Graves, vice-president and general manager, visited the company's mines and smelter during the latter part of April. The matter of reserves of ore is still under discussion. The engineer who reported them to be much smaller than previously stated by the management, 12 years ago was stated to have 'turned down' the Boundary when reporting to a railway company contemplating building into the district. The railway was built, nevertheless, and approximately $46,000,000 worth of ore, reckoning its metal content at New York prices, has been taken from Boundary mines and smelted. An examination by independent engineers would appear to be needed and has been proposed.

Smelter at Trail, British Columbia.

SALT LAKE, UTAH

Utah Con. Mine and Mill. — Utah-Apex. — Bingham & New Haven.—Yampa Smelter.

The Utah Consolidated Copper Co. is still shipping ore from its Highland Boy mine, in Bingham district, to the Garfield plant of the American Smelting & Refining Co., under the terms of an old contract. As is well understood, all Highland Boy ore is to be sent to the International S. & R. Co. as soon as the latter's plant at Tooele is ready for business, and by that time it is anticipated that the Utah Con. will have supplied the Garfield plant with the tonnage of ore specified in the contract. Highland Boy ore, being taken mostly from stopes between the fourth and ninth levels, carries approximately 29% iron, 25 silica, 32 sulphur, 2.8 copper, $1.60 gold, and $0.75 silver per ton. The highest and shortest adit-level is No. 3. The lowest and longest is No. 7, which is in 2600 ft. No. 3 is connected with No. 4 by an incline, No. 4, 5, 6, and 7 being connected by verticals containing ore-chutes and ladder-ways. These adits, which are 100 to 150 ft. apart, vertically, were driven westerly along the limestone which dips north 25 to 45°, and lies between walls of quartzite. The orebodies occur within the limestone, in well defined shoots which have a north dip, an east-west strike, and a northeast pitch. One shoot, as shown by partly stoped-out chambers between No. 6 and No. 7, is 350 ft. long and 250 ft. wide, except that there

are small bodies of waste. The same shoot was opened on the higher levels. Between the sixth and seventh as an example, the worked-out ground, after being timbered with square sets, 7 ft. 4 in. from floor to floor, has been filled with waste derived mostly from outside of the mineral zone. No. 7 adit, which is the main haulage level of the mine, strikes the orebody at a place 300 ft. from the portal and then passes along the quartzite foot-wall. The drifts and cross-cuts from this adit have opened an ore-shoot 600 ft. long, and 200 ft. wide, which shows a decidedly clean chalcopyrite ore in massive bodies. Some of the most interesting work in the mine consists of the workings below No. 7 haulage level. A 250-ft. incline has been sunk on the foot-wall at a point on No. 7 level, 500 ft. in from the portal, attaining a vertical depth of 200 ft. on the ore zone. A skip is operated by an electric hoist in this incline, whereby levels No. 8, 8½, and 9 are established, and from which extensive development has been accomplished and many stopes opened. Development below the haulage level has been further expedited by the sinking of a 200-ft. vertical winze on the hanging wall side, affording two passage ways from levels 8 and 9 to the haulage level. This winze was sunk at a point 400 ft. off No. 7 level, on a short-cut or branch drift. One shoot, as displayed by open stopes between the eighth and ninth levels, appears to be about 350 ft. long and 80 ft. wide. The 18 air-drills employed in the mine permit the breaking of about 800 tons of ore in 24 hours. Present operations in the mine extend through a vertical depth of 500 ft. and on the strike a distance of about 2000 ft. The dimensions of the ore-shoots given are based on fragmentary information, but intended to convey some idea of the orebodies. No. 7 level is equipped with electric haulage facilities by which the ore is taken out in cars and dumped into bins, chutes from which fill the tramway buckets by which the ore is conveyed to the railroad shipping bins. A new track has been built from the portal of No. 7 adit, however, to the new bins at the terminal of the new tramway line over which the ore is to be carried to the smelting plant on the Tooele side of the Oquirrh range.

The mine of the Utah-Apex Mining Co. is entered by a 4000-ft. cross-cut from Car Fork canyon. At the breast of the cross-cut is a 350-ft. vertical 3-compartment raise. Two compartments are for cages. The raise connects with a 600-ft. incline, at 45°, five levels from this go in on the orebody, which lies between limestone and quartzite. Ore from these drifts is dumped into skips which are operated in the incline, and discharge their loads into an ore-pocket at the top of the raise. From this point the ore is lowered to the main cross-cut in cars, and hauled to the portal, where it is dumped into a hopper. The latter discharges into a skip which is drawn up a 200-ft. incline to the mill bin. The ore, which consists mainly of lead and silver in a silicious gangue, undergoes crushing, pulverizing by rolls, sizing by trommels and Callow screens, is passed through jigs and over Wilfley tables. The slime material obtained from these processes is classified in Callow tanks, the coarse from the latter being then re-concentrated over Ishell vanners, a new belt machine put on the market by the Galigher Machinery Co., of Salt Lake. The concentrate produced on the tables and vanners falls into a launder having a conveyor by which it is taken to the foot of an elevator and discharged into a set of tanks where it is de-watered and dropped into cars. The concentration is in the ratio of 3½ tons into 1, and the plant handles 165 tons in 24 hours. A considerable amount of the higher grade ore is shipped without milling it. The superintendency of the mine and mill is in the hands of R. S. Oliver, who has been in that position several years.

At the Bingham and New Haven mine, situated a little farther up Car Fork from the Highland Boy, the main entrance is through No. 3 adit, 3000 ft. long, which receives all the ore from various higher levels. It cuts the first orebody at 500 ft., the second at 900, and the third at 1500 ft. from the portal. No. 3 level is 480 ft. below the old adit that was formerly used. The distance, vertically, between the highest and lowest level is 1800 ft. on the dip of the beds that contain the ore. The workings have opened several shoots of ore. The ore contains copper, gold, and silver. H. J. Turley, superintendent, states that it will assay 4% copper, and contains enough gold and silver to pay treatment charges at the smelting plants. The concentrating mill is undergoing some repairs and it is said the jigs will be discarded. The larger proportion of the ore, according to Mr. Turley, can be shipped. The management of the property devolves upon C. H. Doolittle, of Salt Lake.

The plant of the Yampa Smelting Co., in the lower part of Bingham canyon, is treating 750 tons of ore per day, the major part of which comes from the Yampa mine, about 300 tons per month coming to the plant from custom mines. Frank J. Murphy, superintendent, states that the Yampa ore contains 1.9% copper, 28 iron, 30 silica, 28 sulphur, 3½ lime, 6 alumina. As the ore is received at the plant it is screened, the undersize, which amounts to 425 tons per day, is roasted in nine McDougall roasters, then smelted in two reverberatory furnaces; the oversize from the screens, amounting to 325 tons in 24 hours, is smelted in the blast-furnace. The reverberatory matte contains about 30% copper; that turned out by the blast-furnace about 14. The matte is shipped to another plant for converting into blister copper. The custom ore of the Yampa plant comes principally from the Commercial mine of the Bingham Mines Company.

BUTTE, MONTANA

April Output.—Curtailment Inevitable.—Clark in Merger.

The Butte mines produced 25,087,200 lb. of copper in April. It is likely that the May output will show that the Butte production is again normal, the curtailment agreement apparently being off. The daily output, together with the estimated yield of copper per ton of ore, were as follows:

Company.	Daily Tons.	Lb. per Ton.	Daily Lb.
Boston & Montana	3500	70	245,000
Anaconda	3800	61	231,800
Butte & Boston	500	62	31,000
Washoe	350	60	21,000
Parrot	150	60	9,000
Trenton	400	62	24,500
North Butte	1200	64	76,800
Butte Coalition	1500	65	97,500
East Butte	280	68	19,040
Original	600	63	37,800
Miscellaneous	500	85	42,500
	12,780		836,240

Curtailment is regarded here as highly probable in the near future. The mines in this district at the present time are not running within 25% of their possible output, but the supply is increasing to such an extent as to necessitate further curtailment.

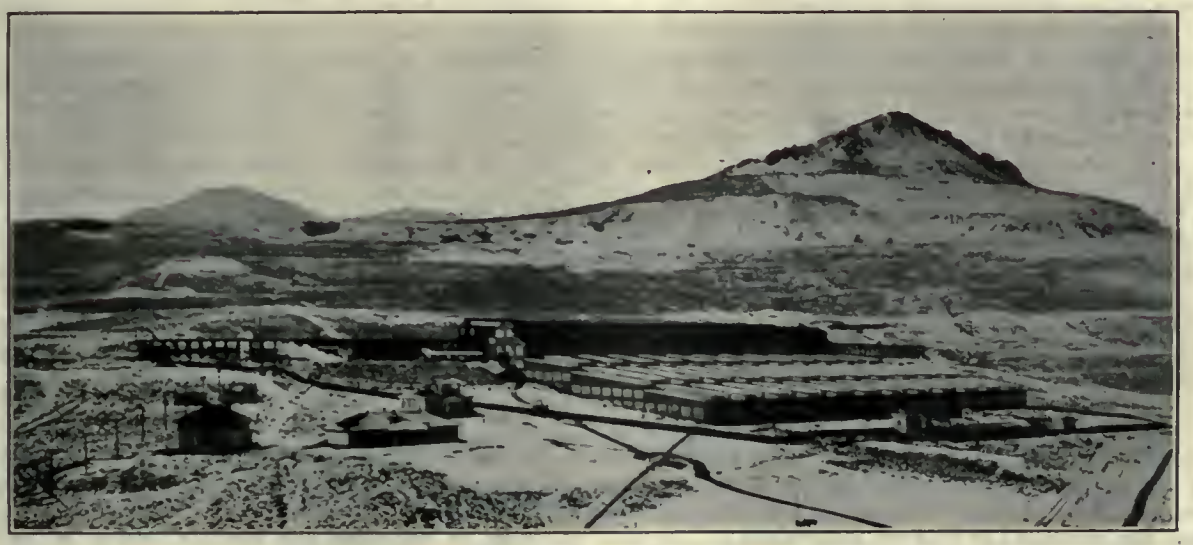
The report persists that the Clark mines are to form part of the merger although nothing can be learned here. It is said that negotiations are proceeding in New York with every prospect of an ultimate agreement. While it is stated that Mr. Clark is willing to accept the terms offered so far as the mines are concerned, he insists that other properties in this city be included, especially the street railway and Columbia gardens. The railway has not made big money and he does not want to sell his paying mines, and still maintain the non-paying properties. A working agreement already exists between Clark and the Amalgamated as to the curtailment of output. When the merger goes into effect the mines of the district will be divided into three operating sections. The Jack O'Neill, who has fought the fire in the Anaconda mine for years, will superintend the mines of the first district, including the Anaconda group and one or two others. William B. Daly, recently named to take charge of the Diamond, Bell, Modoc, Buffalo, Mountain Consolidated, and the Gray Rock, will have charge of the second. The third superintendent has not yet been named. Mr. Daly has been in the employ of the Amalgamated company for several years and is well regarded.

NEW YORK

Copper Producers' Figures May be Abandoned.— Ray Central Bonds.—North Butte Report.— Ray Con. and Gila. — Coeur d'Alene News.—Camp Bird.—Wyoming Copper.

It will take time to heal the sore spots left in the mining market by the shrinkage in some of the copper stocks. There is still much discussion of the threatened abandonment of the work of the Copper Producers' Association. The value of the figures has been demonstrated by the intense interest displayed everywhere in the analysis of the copper situation afforded by the monthly statistics and this ought to be a sufficient reason for their continuance. It has been for many years the custom abroad to publish fortnightly figures covering the visible supply of copper, and, instead of fostering undue speculation the custom has proved a steadying market factor. No small part of the enthusiasm displayed for copper mining during the past eighteen months was builded upon the belief that the leading interests were big enough to warrant good faith. Any withdrawal of confidence now, such as would result from discontinuing the monthly reports, would bring grave results. The sufferers would be not the public but the copper producers. One of the reasons for the present condition is the belief that in order to continue the payment of dividends the low-cost producers will have to take practical command of the copper market. These companies have been paying out practically all of their earnings in dividends and are making preparations for record production. If the copper market should decline another point, to 12c. say, it would mean that the new Anaconda at Butte could not show a safe margin of profit, and while dividends could be continued out of the present large surplus, actual operations might for a time show a deficit. Utah Copper costs are expected to run not more than 7c. per lb., when the enlargements of the Arthur mill of the Boston Consolidated and the Magna mill of the Utah are completed. The two mills will have a capacity of 19,000 tons per day. The Boston has heretofore been worked as an underground mine, but stripping of overburden has already begun and eventually the whole will be operated by the open-cast system. The Ray Central Copper Co. has strengthened its treasury by the issuance of $100,000 of its $2,000,000 bond issue. The balance of the bonds are to be put out only as needed in the course of the development which is progressing under the direction of J. Parke Channing. Attention is being directed to the Tuolumne mine at Butte, owing to the fact that the North Butte M. Co. is just making its annual report. While the report itself has not, at this writing, yet come from the press, it is stated that ownership of the Tuolumne orebody is claimed therein by the North Butte and various dispatches have stated that a compromise agreement has been made between the two concerns. The variety of theories concerning relations of the orebodies illustrate very fairly the absurd complexities of apex litigation. If any contest is to be based on them some fine questions as to primary and secondary mineralization will be raised. A special meeting of the stockholders of the Ray Consolidated has been called to take action on a proposed authorization of an increase in the capital stock of 200,000 shares; the additional stock to be offered to shareholders of the Gila Copper Co. on the basis of one share of Ray for three shares of Gila. It is said that two-thirds of the Gila stock has already been pledged to go into the exchange. At present each company has a capital of 1,000,000 shares, par $10, as Ray Consolidated is selling at $18 and Gila at $6, the exchange is exactly on a parity with the present market. Both companies are controlled by the dominant interests in Utah Copper.

The starting of production by the Stewart Mining Co., the Coeur d'Alene mine controlled by F. Augustus Heinze, and the payment of a dividend by the Caledonia, have brought the Idaho lead-silver camp into renewed public notice. Stewart stock is largely held throughout the East and shareholders have always looked for some real returns from the property. Some two years ago Mr. Heinze had a mill erected for the Stewart upon some adjoining ground upon which he held an option; the mill being erected by a separate company called the Coeur d'Alene Development Co. Later the Stewart failed to make good its agreement to purchase the claims upon which the mill was built and an injunction was obtained preventing its operation with the result that for the past two years a new mill which was built to care for the Stewart ores has stood idle and the company has made no progress whatever. This seems to be a fair sample of Mr. Heinze's way of going into things blindly and winding up in endless snarls of litigation. At the present moment the one time 'Copper King' is on the firing line defending his banking methods and all of the mining properties in which he is interested are suffering from his administration. The settlement of the troubles between the Bunker Hill & Sullivan and the Federal Mining & Smelting Co., together with the recent purchase of control of the Hecla, one of the most spectacular of the recently developed mines of the Coeur d'Alene, has revived discussion of the possible absorption of the Bunker Hill by the Federal. This is a step long desired by the Guggenheim interests in the Federal, but it was strongly opposed by the late D. O. Mills and his interest was large enough to dominate the situation in this regard.



Utah Copper Company's Arthur Mill at Garfield, Utah.

The management of the Camp Bird, Ltd., announces that the last of the payments due to Thomas F. Walsh have been paid. The final payment was made about the time of Mr. Walsh's death, and completed the sum of $2,000,000 which he was to receive in addition to the $3,250,000 cash payment made at the time the mine was sold, the balance being payable as 25% of the net earnings until such payments

aggregated $2,000,000. Camp Bird's earnings are running far above dividend requirements and a nice surplus will soon be available to take care of the development of the recently purchased Santa Gertrúdis or for the purchase of additional property. The long and dizzily crooked path of the Rudefeha-Ferris Haggerty-North American-Penn Wyoming-United Smelters-Railway & Copper Co., has ended in a suit in the Federal court brought by the Penn Wyoming Investors' Association. The name of the protective committee is something of a misnomer, there never were any 'investors' in Penn Wyoming, its predecessors or successors. The shareholders were merely dupes from whom, first and last, a large amount of money was extracted. Some of this was spent on the various properties at Encampment, Wyoming, but, for the most part the promotions and re-organizations of the various companies have been as crooked as Davy Crockett's log—which could not lie still.

WASHINGTON, D. C.

Bureau of Mines Bill Passes Senate. — Land Withdrawal Bill Passes House.—Proposed Seismological Laboratory.

Progress is being made. The Senate has passed the Bureau of Mines bill and it will now go to conference. No serious difficulty is anticipated at this point and the new Bureau, which will mean much to the West, is likely to be promptly organized. In the House after a prolonged and spirited debate, in which much misinformation was bandied about, a bill has been passed authorizing the President to make withdrawals of public lands. This started as one of the nine conservation bills advocated by the administration, but its present appearance would indicate that it were an orphan. The bill as it passed the House is as follows: That the President be, and he hereby is, authorized to withdraw from location, settlement, filing, and entry areas of public land in the United States, including the District of Alaska, for public uses or for examination and classification to determine their character and value; and the President is further authorized when in his judgment public interest requires it, to withdraw from location, settlement, filing, and entry areas of public land in the United States, including the District of Alaska, whether classified or not, and submit to Congress recommendations as to legislation respecting the lands so withdrawn. Section 2. That the Secretary of the Interior shall report all withdrawals made under the provisions of this act to Congress at the beginning of its next regular session after date of the withdrawals, specifying the purpose of each thereof. All withdrawals heretofore made and now existing are hereby ratified and confirmed as originally made under this act. All withdrawals shall remain in force until revoked by the President or by Congress.

The bill as reported by the Public Lands Committee contained amendments which provided that the withdrawals should not affect the legal rights of any settler or entryman initiated prior to such withdrawal, and that upon "restoration of any such lands in the United States the equitable rights shall attach of any bona fide claimant who prior to such withdrawal initiated a claim thereto and made valuable improvements thereon." These were defeated. These amendments precipitated a perfect maze of parliamentary tangles. Speaking upon the amendments proposed by the committee, Scott Ferris, from Lawton, Oklahoma, said that this committee amendment if adopted would undo everything that the bill proposed. It would clear list and pass to patent every claim and entryman's right that has been initiated throughout the United States and Alaska. He charged that the amendment was formulated in the committee by hands unfriendly to conservation. Frank Mondell, of Wyoming, chairman of the committee, retorted that the Democrats were trying to make this bill so objectionable and so drastic that it would turn the tide in their direction, because of the fact that a Republican Congress denies the rights of honest, bona fide entrymen.

William F. Englebright, Nevada City, California, representative, suggested the following amendment: "Provided, however, that all lands withdrawn under the provisions of this act shall be open to exploration, discovery, occupation, and purchase, under the mining laws of the United States, so far as the same apply to metalliferous minerals." He said the object of his amendment was to protect the prospectors engaged in prospecting for the precious and other metals. In spite of similar pleas, the amendment was defeated. Mr. Mondell told the members of the House that there was no fear of the rapid depletion of the coal supply of the country; that but one-half of one per cent of the total supply had been used up to date. He declared that at the present consumption, his State alone, Wyoming, had sufficient coal to supply the country for 3000 years. It is evident that the bill, as it passed the House, will be changed materially before it passes the Senate. Reed Smoot, Senator from Utah, has already introduced a new bill in the Senate, covering the withdrawal of public lands and providing that all lands withdrawn shall be open to exploration, discovery, occupation, and purchase, under the mining laws of the United States, so far as the same apply to minerals other than coal, oil, gas, and phosphates. His bill also contains the provision that such withdrawals shall not affect the legal rights of any settler or entryman initiated prior to such withdrawal.

The indications are that the Federal Government will soon take up a thorough study of seismologic disturbances. The committee on the Geological Survey has recommended that $20,000 be appropriated for a seismological laboratory under the direction of the Smithsonian Institution. This will be added to the Sundry civil appropriation bill as an amendment. The committee in its report states that the Smithsonian Institution is the proper organization to have charge of the laboratory. Before making its recommendations, the committee requested information from Charles D. Walcott, Secretary of the Smithsonian Institution; George Otis Smith, Director of the Geological Survey; and Willis L. Moore, chief of the United States Weather Bureau. The committee called particular attention to the memorandum submitted by Mr. Walcott. His views are as follows: "The immense destruction of life and property by certain large earthquakes emphasizes the importance of investigations which may lead to a reduction of the damage of future earthquakes. The science of seismology is in its infancy, and it is not always evident what lines of investigation will yield the most important results, hence the importance of developing larger knowledge of seismology in all directions. As an example: It was not at all realized that the accurate surveys of the coast and geodetic survey in California would demonstrate that the great earthquake there in 1906 was due to forces set up by slow movements of the lands which have probably been going on for a hundred years. We have learned that slow movements of the land must precede many large earthquakes, and monuments are now being set up in California to enable us to discover future movements of the land and thus to anticipate future earthquakes. This, I think, is the most important step so far taken toward the prediction of earthquakes. Seismological work is too large to be prosecuted successfully by the universities, but requires some central office under Government supervision to encourage theoretical and observational studies and to collect and to study information from all available sources. The various departments of the Government could offer material help. The Weather Bureau could furnish information regarding shocks and could maintain seismographs at some of their stations. Postmasters throughout the country could also report earthquakes. The Coast and Geodetic Survey could maintain instruments and adapt their surveys and tidal observations to the detection of slow earth movements. The army could give information regarding earthquakes felt at their outlying posts: the navy, regarding earthquakes felt at sea. The Geological Survey could furnish information regarding the geological structure of earthquake regions. The seismological laboratory would collect and study all this information. It would serve as a clearing house for the whole country. It would also be the link to connect seismological work in this country with the work done in other parts of the world. Its director should represent the United States in the international seismological association, which this country has joined through the Department of State."

General Mining News

ARIZONA

COCHISE COUNTY

The case of H. F. Gilbane, representing the Copper King Mining Co., against Hoval A. Smith, C. M. Henkle, and R. E. Bretherton, to regain title to mining ground in the Warren district, alleged to have belonged to the former company has been decided in favor of the defendants by Judge Doan of Tombstone. The group comprises 10 claims adjoining the Copper Queen, the C. & A., and Denn Mining companies. There is a 600-ft. shaft and considerable driving has been done on the property opening good ore. The mine has been closed down for the past three years, but it is thought that within the near future steps will be taken to re-open it for further development.

GILA COUNTY

(Special Correspondence).—Sinking continues in the McGaw shaft and Great Eastern winze of the McGaw workings of the Superior & Boston mine, near Globe, and regular shipments of 80 tons of ore per day are made to the Old

Map of Arizona.

Dominion smelter. Two winzes, sunk from the 400-ft. level of the Gardner shaft, are 125 ft. apart and have opened the vein which assays 8% copper to depths of 40 and 55 ft. below the level.——The cross-cut on the 660-ft. level of the Williama shaft of the National Mining Exploration property is now 64 ft. long, and has intersected a small vein of copper ore assaying 39% copper.——At the 420-ft. level of the Miami mine ore-pockets are being cut at the station and the development work started for the second haulage level 150 ft. below the first one.

Globe, April 29.

YAVAPAI COUNTY

Operations have been resumed at the Spar mine of the Pocahontas Mining Co. three miles southwest of Mayer and grading for the new mill completed. There have been two shafts sunk on the property to a depth of 100 and 200 ft. The 100-ft. shaft is near the mill-site and it is here that the company intends to do its most active work.——The Mount Elliott Mines Co. is sinking the two main shafts at the Dividend and Ticonderoga mines and running the mill one shift. As soon as the power line is completed from Poland Junction the company will increase the amount of ore taken from the mine and operate the mill continuously.——The shaft of the Grand Mountain Mining Co. a few miles east of McCabe is down 150 ft. and the company is installing a new hoist. New living quarters, a blacksmith shop, and assay office are also being erected. F. L. Dwight is manager.

YUMA COUNTY

At the Clara Consolidated, at Swansea, operations are being confined to development and at present five shafts are being sunk and drifts from each of these have opened ore. Practically all the machinery for the smelter has been delivered and it is expected that the plant will be ready for operation in a short time.

CALIFORNIA

INYO COUNTY

C. A. Fohrman, manager for the Casa Diablo Gold Mining Co., operating the Casa Diablo mine 20 miles north of Bishop has returned from the East and is now at the property. At present the ore is being mined from the Dry Bone vein and the mill in which a new 40-hp. motor has been installed is kept running night and day. It is the intention of the manager to sink to the 500-ft. level and explore the vein at that depth.

MARIPOSA COUNTY

A tramway, bunkers, and spur connecting with the railroad have been completed at the Baryta mine of F. M. Smith a few miles below El Portal on the Merced river and shipping will be started in a short time. The material, of which there is a large amount opened in the mine, will be shipped to Oakland to be used in the manufacture of paint.

NEVADA COUNTY

Machinery for a new 5-stamp mill at the Montana mine has been hauled from the foundry at Grass Valley to the property in Willow valley and is now being erected. A considerable supply of ore has been blocked out at the mine and it is expected that the ore reserves can be kept well ahead of the stamps.——The Champion Gold Mining Co. has failed to make the payments due on the bond under which it took over the Champion mines, near Nevada City, and the Champion Mines Co. has resumed work in the properties. The men employed by the former company have attached the ore broken in the stopes for back wages.

PLACER COUNTY

Two parties working for W. P. Hammon are testing the ground in Auburn ravine to determine its value for dredging. It is reported that the holes sunk so far have been successful in opening gravel containing enough gold to warrant the installation of a dredge.——The El Dorado & Placer Counties Gold Mining & Power Co. has purchased four miles along the middle fork of the American river embracing some 6,000,000 yd. of gravel, and will install complete equipment to work the claims. Power for steam-shovels will be obtained from Clipper Gap.——At the Dewey the adit is in hard rock and is expected to tap the shaft in a few days.——The Red Sea channel has been opened at Forest and excellent gravel is being taken out.——S. A. Hendren, who has been operating the extension of the Black Oak mine east of Weimar, has opened a 28-in. vein that assays from $25 to $75 per ton.

SHASTA COUNTY

All the electrical appliances and most of the steel for the Balakiala company's smoke-consuming plant have been ordered and work on the foundation started. Construction will be rushed and the company will have the plant ready for operation by July 1, which was the time agreed on by the Farmers' Association.——It is reported that Chicago capitalists are arranging to resume work on the Friday-Lowden copper group, and that arrangements have been made whereby the ore will be treated at the Mammoth and Balakiala smelters.——The U. S. Gold Dredging Co. is arranging for more extensive work on its holdings along Clear creek.——The Consolidated Gold Dredging Co. reports that activity will soon commence on the ground recently secured.

SIERRA COUNTY

Operations have been started at the Lookout property in

the Alleghany district and an adit is being driven to tap the vein. The property is on Kanaka creek and adjoins claims that have been good producers.——The old Joel Bean mine at Scales is being operated with a small crew. The company last year completed a large concrete dam that will be capable of restraining the débris for several years.—— The Poker Flat Mining Co. has resumed work in the shaft of the property on Poker flat.——The machinery at the Gibraltar mine is being overhauled and work will be started as soon as the snow melts.——A shoot of rich sulphides has been opened near the surface of the vein at the High Commission group east of Downieville and an adit started to cut the ore at greater depth.——Camp & Ish have lately obtained a number of good assays from the Tippecanoe and Jumper claims near the head of Slate Castle ravine which they are operating under bond.——The raise which is to be used for an air-shaft at the Bunker Hill mine has been completed. The gravel that was worked on a bench about a month ago paid well, but the bedrock pitched away, and after following it for 20 ft. with a winze bad air made operations difficult, so the raise was started.——F. O. Richardson and Chris Davis of Monterey have obtained a bond on the Black Warrior and Etta G. claims in Sailor ravine. ——The cross-cut in the hanging wall at the Gray Eagle mine opened a new vein, and drifts have been started to develop it.

SISKIYOU COUNTY

Work has been started for the season at the Homestake mine on Taylor creek.——The Siskiyou Syndicate is preparing to resume work on the Bordman group in China gulch.——A 20-in. vein assaying $40 per ton has been cut at the Frietas-Lynn mine by the lower adit.——After a temporary shut-down of three weeks the Golden Indian on Indian creek has resumed operations under different management.——Twenty-five tons of high-grade ore have been taken from the Old Turk mine and will be crushed in an arrastre near the property.——A new bridge has been completed across Punch creek and ore is being hauled from the Red Ant mine to the quartz mill at Yreka. R. M. Brown, the superintendent, reports that a 3-ft. body of good milling ore has been opened recently.

TRINITY COUNTY

George Lewman, in charge of six or eight men, is working on the old Poker Bar hydraulic mine, below Lewiston. Machinery is being removed from the old dredge and an elevator is being put in to prospect the ground. The old Poker Bar dredge was operated several years ago, but not with much success. The company that has now taken hold will erect a modern dredge and develop the property if the prospecting turns out as well as expected.

TUOLUMNE COUNTY

(Special Correspondence.)—The company which has taken the Duffield mine, near Arastraville, is preparing to commence development work. Machinery and a large quantity of pipe are being taken to the property and a 75-hp. motor is expected to arrive soon.——The remodeling of the mill at the Draper mine has been completed and the 10 stamps will be started at once. The property, since passing into the hands of E. J. Cotton and Andrew McCormick, has been extensively developed and the owners are more than pleased with the outlook. The shaft is now 600 ft. deep, and the several drifts show large quantities of high-grade ore. R. A. Nicholls is superintendent.——It is expected that the new shaft being sunk at the Eagle-Shawmut mine will be connected with the old shaft, 400 ft. below the surface, by May 15, when complete operations will be resumed with the usual force of more than 200 men.—— Operations will be resumed immediately at the Keltz mine, of which H. L. Houston is superintendent and part owner. Additional machinery will be installed.——Everything will soon be in readiness for beginning hydraulic operations at the Red Gravel mine.——A well defined vein has been cut 190 ft. from the surface at the Gold Crater mine.

Tuolumne, May 2.

McRae & Baum have cut the vein on the 100-ft. level of the Ida Klein mine in Yorktown gulch and obtained a number of good assays.——At the Yrma the shaft is down 90 ft. on the vein, showing a width of 6 ft. at the bottom. Sinking will be continued to the 150-ft. level before any drifts are started.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—From this time forward it is expected that the Central adit on Believue mountain will be advanced at the rate of 200 ft. per month. For the past year 90 to 100 ft. of ground has been broken monthly.—— The Roberts concentrating plant at the Lamartine mine was put in operation on material from the dumps a few days ago and steady shipments will be maintained.——Work has been put under way in the sinking of a new shaft on the Chicago Belle mine on Chicago mountain. At a depth of 30 ft. an 18-in. streak of $21 ore has been cut.——The switch to connect the railroad tracks with the Malm chemical-electro plant was completed the first of this week. Since then five carloads of machinery have been shipped from Denver. W. E. Malm, in charge of construction work and installation of machinery, states that the plant will be ready to begin operation July 1.——Construction work on the new 100-ton mill building for the Conqueror Mining & Milling Co., operating the Conqueror mine on Covode mountain, was started last week. The grading has all been completed. This mill will be in operation by July 15. J. C. Sturdevant of Empire is manager.——Machinery for the 10-stamp mill in course of construction for the Mint mine being operated by the New System G. M. Co. is arriving and a force of men is being employed in placing the same in position.

Georgetown, April 28.

GILPIN COUNTY

(Special Correspondence).—N. McKay, leasing on the War Dance mine in Russell district, sent out a shipment of three tons of ore last week that milled 26 oz. gold and 28 oz. silver per ton. At the same time three tons of second-class ore was marketed that brought a settlement of 7 oz. gold and 27 oz. silver per ton.——Active development is in progress at the Gold Collar mine in Eureka district. Work is being centered in the east drift from the 350-ft. level of the shaft. The management is considering erecting a new mill. A. Skeels is manager.——The Hubert mine in the Nevada district is the scene of a discovery on the 500-ft. level west. The streak is from 6 to 10 in. wide and will mill better than $35 per ton in gold and silver.

Central City, April 30.

LAKE COUNTY

Work is to be started at once at the Big Four property on Breece hill in the Leadville district by the Crawford Mining Co., a corporation composed of Boston and Chicago capitalists. The company will work the Big Four south shaft and will not extend its workings to the Gold Basin mine, which was formerly a portion of the property.—— The winze in the St. Louis adit has been completed and lateral work started to further open the mine.——The Curan adit has been started from the south side of Big Evans gulch and will be driven to cut under the Highland Mary and adjoining claims.——It is reported that new pumps are to be installed in the Pyrenees property on Carbonate hill and work resumed in the mine. Operations have been suspended three times at the property on account of insufficient pumping capacity.——Arrangements are being made for the resumption of activities at the Anona mine on Long & Derry hill. The property has been idle for the past year, though two years ago the plant was connected to the wires of the Leadville Light & Power Company.

TELLER COUNTY

Sub-lessees from the Western Investment Co. on the Empire State mine of the Isabella Mines Co. in the Cripple Creek district are mining high-grade ore, and recently settled for a 30-ton lot at a rate exceeding 6 oz. gold per ton. The net amount to the lessees, after deducting freight and treatment charges and royalty to the owning company, was approximately $2000. The Western Investment Co. is also mining a good average grade of ore, and during April shipped the largest tonnage since acquiring the lease.——An

immense body of low-grade milling ore has been exposed by cross-cut on the Nellie V., a fractional claim on Gold hill, owned by the Lexington Gold Mining Co., and operated by Iver Weston and associate lessees. The ore assays from $3 to $7 per ton, but the present freight rates prohibit shipping ore of this value, so a small lot is being tested to ascertain if it will be profitable to build a mill at the property.——Shareholders of the Elkton Consolidated Gold Mining Co. are receiving checks to the amount of $37,500, mailed from the home office in Colorado Springs. The Elkton company has paid its shareholders two bi-monthly dividends of this amount this year, a total to date of $2,554,460. The main shaft on the Walter claim in the town of Elkton is producing ore of the gross bullion value of approximately $35,000 per month, and only one shift with about 75 miners is employed.

IDAHO

IDAHO COUNTY

The Elk City Mines Corporation, which recently acquired the South Fork, formerly the Espey mine, in the Elk City district, from the Adams brothers of Atlantic City, New Jersey, has been incorporated under the laws of Washington with a stated capitalization of $1,000,000 by W. H. Stowell, Robert A. Koontz, W. D. Greenough, and J. T. Omo, of Spokane, and William Hare, of Tekoa. The chief development will be the extension of the main adit and the advance of deeper workings. More than $2000 per month in bullion bars has been received by banks in the district from the South Fork mill, and it is expected that the improved machinery and cyanide tanks to be installed will increase the output. The prospective sources of additional profit are ore on the dump valued at $50,000 and $100,000 worth of tailing in the creek.

SHOSHONE COUNTY

M. W. Bacon, secretary and general manager of the Stewart Mining Co., announces that the Mammoth mill at Wallace, owned by the Federal Mining & Smelting Co., has been leased by the Stewart company and will be put to work on the Stewart ores immediately. The Mammoth mill is a 354-ton plant and is in good condition. The Stewart has 10,000 tons of ore on the dump and enough more blocked out to insure the steady running of the mill. The mine is situated near Wardner. It was sold to F. Augustus Heinze by H. F. Samuels and associates for $400,000 in 1905. The Mammoth mill is about 14 miles up the North Fork of the Coeur d'Alene river and within a mile of Wallace.——It is reported that a 12-ft. vein of high-grade concentrating lead-silver ore has been cut on the 300-ft. level of the Alice mine. The mine has been developed extensively and bodies of galena ore have been opened on several levels, but the present find is the richest. The 200-ton concentrator recently installed is working perfectly and is said to be one of the best plants in the district.

KANSAS

CHEROKEE COUNTY

(Special Correspondence).—At Galena camp, as throughout the Joplin field, shallow mining is reviving. Several companies are opening old tracts southwest of town, making in all about 600 acres open to small investors. Two famous producing tracts, the Battlefield 40 and the Luscombe & McElroy 40 have just been opened the last week. Both were extensively mined in the early days and both are filled with old drifts and shallow shafts which have been filled to the surface with water. The present company has installed heavy pumping machinery and will easily drain the ground. It will not be necessary to do a great deal of prospecting before beginning active operations, as the old works show rich deposits. The lower levels have never been touched and these as well as a large amount of shallow ore are available. Part of the ground will be sub-leased, while the deeper ore will be worked by the owners.——The Boston company, too, has taken 400 acres southwest of Galena which is also being developed. Much of the shallow ore will be worked through the open-cut method, while the deeper will be through shafts and drifts. The open-cut work will be done by the company, while the remainder will be leased. A portion of the land never before worked will be drained and made ready for leasing.——The Eureka mill, one of the largest in this camp on the Ping & Robertson land, has at last been started after a long wait for sufficient water to accumulate in the pond. The mill is new and its starting marks an innovation in the way of deep mining, only the Herald company in this district being at work in the deep levels. Hitherto all mining in the Kansas field has been confined to the shallow but rich pockety deposits, which are not generally so extensive or long lived as the deeper levels.——The mill belonging to Stone, Pinson & Hallam on the Black Hills 40 has been started and will be run on custom ore for the present until the ground is sufficiently opened to operate on the company's own ore exclusively. The plant is run by electric power.

Galena, April 22.

MISSOURI

JASPER COUNTY

(Special Correspondence).—In the entire district shallow ore mining is reviving in various camps, reminding one of the early days of the mining industry in this field. At Tuckahoe, northwest of Joplin, the latest discovery has

Mill in Joplin District.

been made by J. M. Short, where the drill penetrated a 14-ft. vein of ore assaying 20% zinc. The ore was struck at 118 ft. and again later at 152 ft. It is thought to be a continuation of the rich old ore deposits worked in the Tuckahoe camp which made that part of the field famous several years ago. The latest find was made on the Brinkerhoff land. Other drill-holes will be sunk and the deposit thoroughly developed.——On the Rex land southwest of Joplin the Elizabeth Mining Co. has six shafts in ore at the 100-ft. level in ore said to run high in both lead and zinc. Much of the ore can be hand-jigged and no mill will be built for the present.——Several shallow mines have been developed on the Anderson farm at Carl Junction as a result of a find made there several months ago. The most favorable is that of McFaren & Co., who have drifts at 37 ft. which is not the bottom of the run. There is a considerable quantity of both lead and zinc in the bins which have been cleaned with hand-jigs. In some of the shafts the ore was found at as shallow depth as five feet, which, though thin, led downward to a much better grade of ore. These developments are on virgin ground far from other operating mines.——Another body of ore has been cut in the vicinity of Toms Station in new drill-holes put down by Wells Brothers. In each hole ore was struck at 142 ft.,

passing through 11 ft. of lead ore when zinc was entered continuing to 184 ft. This made in all an ore face of 42 ft., part of which assays as high as 17%. The new find is near the Katherine and Freeman mines.

Joplin, April 23.

MONTANA

JEFFERSON COUNTY

In the Corbin district the Montana Corbin Copper Co., which is developing the Hidden Treasure property, is making occasional shipments of high-grade ore. The vein is being stoped on the 400-ft. level, where 2 ft. of chalcopyrite ore has been opened.——The Boston & Corbin has opened a good body of bornite on the 700-ft. level and has considerable first-class ore in the bins which it expects to ship at an early date.——A winze is being sunk in the adit level of the Butte & Corbin Consolidated and some good ore opened.——At the London-Corbin Exploration Co.'s property the showing in the adit is improving and the company has started a double compartment shaft that will be sunk to the 200-ft. level before cross-cutting is commenced.——The shaft at the Corbin Metal is down nearly 400 ft. It is the intention of the company to sink to the 700-ft. level before doing any extensive exploratory work.

NEVADA

CLARK COUNTY

The pipe-line from Tule springs to the Capital mine in Eldorado canyon has been completed and the camp is now supplied with a good flow of water. In the mine cross-cutting from the 200-ft. station has been started to open the vein on that level. Two carloads of ore are to be forwarded to the Needles smelter in a few days.——The south cross-cut on the 300-ft. level of the New York Searchlight opened a 20-ft. vein when out 100 ft. from the shaft. The ore is an oxidized quartz considerably copper stained and shows some free gold when panned.——At the Good Hope mine lessees have opened a vein on the 85-ft. level that is about a foot wide and assays $30 per ton. The ore is being stored near the shaft and will be crushed in the Knight mill within the next few days.

ESMERALDA COUNTY

The Goldfield Consolidated Mining Co. will soon erect a new 2000-hp. transformer station near the old Combination mill. At the present time the Consolidated company is using something over 1000 hp.——The Lind lease on the Booth continues to show steady improvemeut since what is believed to be the northeasterly extension of the Red Top vein was cut by the east cross-cut on the 360-ft. level some days ago. Drifts have been started along this vein, which is more than 10 ft. in width, to the north and south from the point of intersection, and each drift is now out some 35 ft. from the cross-cut.——The Florence mill is steadily handling an average of 160 tons of ore per day. In the mine 24 to 26 drills are being steadily used in development work alone. On the seventh level of the main workings extensive driving is in progress, as on this level the downward extensions of orebodies opened in the upper levels are being rapidly picked up and preparations made for extracting the ore when it is needed. Bulkheads and ore-chutes are being put in as rapidly as stoping ground is opened. On this level the Florence vein system will soon be opened from the old Reilly lease workings through to the Little-Florence.——The mines of the State of Nevada produced, during the year 1909, $25,000,000, according to the official report of James F. Haley, State Bullion Tax Agent, which report has just been submitted to Governor Dickerson. The above figures apply to the production as officially reported to the Bullion Tax Agent, and upon which production bullion taxes were paid to the State. The figures show that Esmeralda county, of which Goldfield is the county-seat and centre, led the counties of the State in value of mineral produced, with an output of $9,587,831. White Pine county, of which Ely is the county-seat, was second with a production of $7,114,354, and Nye county, of which Tonopah is the county-seat and mining centre, is third with $5,740,581. Eureka is fourth with a production of $815,088. On the other hand, the copper properties of White Pine county led in the point of tonnage of ore handled, as it shows 1,678,895 tons of ore produced, as against the 509,801 tons produced by Esmeralda county, with its gold, silver, and lead properties. Nye county comes third with 374,827 tons of ore produced during the year.

LANDER COUNTY

(Special Correspondence).—The Austin-Manhattan Co. is arranging to re-timber the Ophir shaft and is sinking from the 380-ft. level an additional 100 ft. The surface plant will be removed to this point from the Frost shaft and the first unit of the mill be installed at once. Walter W. Wishon is general manager.——The Kimberly Mining & Reduction Co. has been formed with a capital stock of $3,000,000 to erect a custom mill at Kimberly. It is stated that the plant will have a capacity of 200 tons per day.——The owners of the Yellow Jacket mine in the Reveille district report the uncovering of 40 ft. of silver ore. A small amount of gold also occurs. About two feet is said to assay over 300 oz. per ton.——The Shoshone Quicksilver Co. is opening a large body of ore containing a high percentage of mercury. The Nevada Central railroad management announces that regular trains will be in operation about the middle of May. The washouts are being repaired as rapidly as material can be delivered. A number of mines in this district are idle because of lack of supplies and working materials, caused by the blocking of the railroad.

Austin, April 28.

NYE COUNTY

The report of the Tonopah Mining Co. for the year ended February 28 has just been issued, showing the total net earnings for the year were $1,639,602, of which $1,400,000 was paid in dividends. The average gross value of the ore was $20.93, the extraction amounting to 91.7%.——The survey from the main spur of the railroad to the new Belmont shaft at the Belmont mine has been completed and the site for the new ore-bins will be 240 ft. northeast of the shaft. A new compressor and steel head-frame have been ordered and will be installed in a short time. At Millers the mill has been overhauled and all the stamps will be dropping by the middle of the month.——The Midway Mining Co. continues work on the big vein intersected by the winze from the 535-ft. level. The vein is inclined to be pockety, with the best value in a streak near the hanging wall.

STOREY COUNTY

At the iron properties being developed 14 miles northeast of Virginia City the shafts are down 100 ft. and cross-cuts have been started to prospect the ground between them. At the present time there are 30 men working at the property. The outcrop has been traced for several miles, showing a width of 2000 ft. in some places.——Two 4-horse teams are now hauling ore from the Dietrich lease on the Best & Belcher surface workings to the Fisher mill in Sixmile canyon.——A drift on the north line of the Gould & Curry claims is being run near the surface and some good ore is being opened.——The Consolidated Virginia is extracting low-grade ore for the mill from the 1750 and 1800-ft. levels, and it is stated that a west cross-cut will soon be under way from the eighth floor of the raise on the 1750-ft. level. The raise is now up over 60 ft. and has passed through favorable formations.——There is greater activity in the Gold Hill mines at present than at any time during the past fourteen years. More men have employment and large areas of new ground are being opened that are giving immediate good results. With the unwatering of Gold Hill to the 1800-ft. level through the Ward shaft still greater activity may be expected from this group.

WHITE PINE COUNTY

A new ore-bin has been erected at the Millard lease north of Lane and another load of ore is ready to be forwarded to the smelter.——McGill & Willoughby have cut the Southern Cross vein at the Chainman property and have started the mill on the ore.——In the Ely district 2 ft. of good lead-silver ore has been struck in the raise from the east drift of the American mine on the Ely Consolidated, which promises to afford much good stoping ground. The Brilliant mine of the Ely Consolidated is looking comparatively

well and the south drift of the Zack mine is all in low-grade ore at the present time.——It is expected that the Nevada Consolidated will commence operating its new steam-shovel pit on the Liberty claim within a week or ten days. The company has three steam-shovels on the road and five donkey engines, all of which will be used in the removal of the overburden. At this point the sulphide zone comes very near the surface.——The winze from the 1100-ft. level of the Boston Ely is now down 86 ft. and is bottomed in sulphide ore, which is just coming in. The ground is much harder than it has been above, hence the winze is going down at about 2½ ft. per day.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The Socorro Mines Co. has made good progress during the week in changing the Burt filter-press operations from the power to the gravity system. Development was advanced 150 ft. and 700 tons of ore milled averaging $18 per ton. Five bars of bullion and 100 sacks of concentrate were produced. The high-grade ore continues in the 300-ft. level west, all of which is being sacked as mined.——The Ernestine Mining Co. produced 6710 oz. of bullion, 61 sacks of concentrate, and milled 715 tons of ore during the week. This company has also opened a good body of sulphide ore on its 300-ft. level west.——Good progress is being made installing the pipe-line by the Helen Mining Co., completion of which is expected within 90 days. Practically all the required material has been delivered at the plant at Graham.——For the past week the drift in the Crescent adit of the Alberta Mining Co. has shown a decided improvement, with the vein measuring about 13 ft., although the andesite in the hanging wall is still full of quartz seams.

Alma, April 28.

OKLAHOMA

L. L. Hutchison, Assistant Director of the Oklahoma Geological Survey, has just sent to press a special State report on the asphalt, oil, and gas deposits of Oklahoma. This report is divided into two parts. In part one, Mr. Hutchison gives a general map which shows that portion of the State in which asphalt occurs and the region where it is likely to be found. It also contains a geological map of the asphalt-bearing district, and one showing the exact location of nearly one hundred known deposits, all of which have been visited by the author or his field assistants. This part of the report is closed with a chapter on asphalt paving that contains suggestions to cities and towns which contemplate paving. Part two is devoted to oil and gas and reviews the history of the industry and discusses the various theories of origin and accumulation of petroleum and natural gas. This section of the report is illustrated by a general map showing the present developed areas, probable territory yet undeveloped, and those parts of the State where it seems possible that oil and gas may be found, and by a geologic map of the oilfields and detailed maps, which give the exact location of every well drilled in the various important fields prior to 1910.

UTAH

BEAVER COUNTY

(Special Correspondence).—The Moscow Mining Co. is shipping two cars of ore per week, and this probably will be increased. The ore consists of a lead-carbonate containing silver. The orebody is said to have been opened a distance of 350 ft. on the vein. A 70-ft. raise and a 90-ft. winze are in ore.

Newhouse, April 30.

SALT LAKE COUNTY

(Special Correspondence).—The Utah Leasing Co., composed of J. C. Dick and associates of Salt Lake, is operating the Old Telegraph mine, in upper Bingham, under a three years' lease from the United States Smelting, Refining & Mining Co. The property had been idle for some time prior to the time this lessee began work last June. At present the ore shipments consist of 600 tons per month of siliceous ore to the Garfield smelting plant for converter lining; 200 tons of copper ore per month to the plant of the Yampa Smelting Co.; and 200 tons per month of lead ore to the U. S. company at Midvale. The siliceous ore carries some gold and silver, and runs 85% silica. The copper ore contains 5 to 6% of that metal, with gold and silver aggregating $5 per ton. The mine is entered through an 800-ft. adit, all ore that is mined being taken from stopes above this adit. The orebody occurs as a deposit overlying a bedding of quartzite, the three kinds of ore being definitely separated from each other. The work is under the superintendency of N. M. Muir, who states that there is a considerable tonnage of the siliceous ore accessible.——The Old Jordan mine, of the U. S. Smelting, Refining & Mining Co., is producing 250 tons of lead ore per day; this is conveyed to the shipping bins at the railroad over the company's four-mile aerial tramway. J. F. Barnard has charge of this property as superintendent.——The North Utah Mining Co., owner of the Butler-Liberal mine and other mineral ground in Markham gulch, Bingham district, has shipped 20,000 tons of lead-silver ore to mills and smelting plants within the last year, this production having been incidental to development. W. D. Bohm, the company's manager, states that a 163-ft. shaft has been sunk from the main adit level on the Butler-Liberal and that 900 ft. of horizontal development has been done from the bottom station of this shaft. The ore-channels sought have been found and further development will doubtless be most interesting.

Salt Lake, April 30.

SUMMIT COUNTY

(Special Correspondence).—The New York Bonanza Mining Co., whose development work is in charge of M. J. McGill, has sunk a 2-compartment shaft to a depth of 1000 ft. in limestone, and driven a number of cross-cuts to a quartz fissure. The property is in Ontario canyon, 3500 ft. south of the Ontario shaft, and three miles from Park City. Since beginning they have shipped ore that sold at $72,000, some of which was taken from stopes between the 600 and 800-ft. levels, and the rest from a winze on the 400. Present work is confined to the 800-ft. level, but the company will resume on the 1000-ft. level as soon as the spring flow of water has had time to drain out of the lower workings. The average of the ore shipped ran 100 oz. silver per ton, and 10% lead; some, however, contained 176 oz. silver, 20% lead, $2.50 per ton gold, and 2% copper. The ore carries 60% silica and all below the 850-ft. level is sulphide. The old Daly dumps, which resulted mainly from operations twelve to twenty years ago, have been leased to A. W. Davidson and Ole Johnson, who are working over portions by hand-jigging.

Park City, April 30.

CANADA

ONTARIO

The annual report of the Nipissing Mines Co. recently issued shows that dividends aggregating $1,500,000 were paid during the year, that ore in transit and at the mine amounted to $400,000, that net earnings for the year had increased $775,000, that the ore reserves were estimated at $3,269,000, and that the company had over $100,000 surplus in the treasury.——The Agaunico, on the shore of Lake Temiskaming, has cut the Huronian slates at a depth of 250 ft. The company is working 30 men and a 5-drill compressor is operating two large machines. At the 200-ft. level a cross-cut opened the big smaltite vein where it showed a width of 30 in. It assayed high in cobalt but low in silver. The shaft at the present time is down 255 ft. and will be sunk to the 300-ft. level where the vein will again be picked up in a cross-cut.——There are now two plants running in the Porcupine camp. One is the Crown Chartered, in the neighborhood of the Bannerman and Davidson claims, in the northern end of the camp, and the other is the Timmins in Tisdale, near Pearl lake. The Wilson has a small stamp-mill. The Timmins are now probably the largest holders of valuable property in Porcupine. They have the Hollinger, the McMahon, the Gillies, the Miller, two Bruce claims, and five Armstrong and Booth claims all in one block. Upon all of these claims valuable discoveries have been made, so that the need for a large equipment such as they have now installed is apparent.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MECHANIC'S LIEN ON MINING PROPERTY.

The mechanic's lien statute of Utah is intended to apply to all persons who shall work or furnish materials for the working, preservation, or development of any mine, lode, mining claim, or deposit yielding metals or minerals of any kind, or for the working, preservation, or development of any such mine, lode, or deposit, in search of such metals or minerals and to all persons who shall do work or furnish materials upon any shaft, tunnel, incline, adit, drift, drain, or other excavation of any such mine, lode, or deposit. The statute also provides that when two or more such lodes or deposits, owned or claimed by the same person or persons or where the owners are different persons, and the same with the consent of all shall be worked through a common shaft, tunnel, incline, adit, drift, or other excavation, then all the mines, lodes, or deposits so worked shall, for the purposes of the statute, be deemed one mine. In an action to enforce a mechanic's lien against mining property, the Supreme Court of Utah held that the proviso was not such in fact, as it did not restrict or modify what was previously said in the section, but was intended to apply to the whole chapter and that for the purpose of arriving at the true intention, the proviso should be considered as a separate section of the statute; and that for the purpose of acquiring a mechanic's lien under this proviso against mining claims which are operated as a mine, the claims constituting the mine and all the property necessarily used and connected with the mine and mining claims, including an easement in adjoining lands, used as dumping grounds as a necessary appurtenance to the mine, must all be regarded as a unit and to all of which the lien would attach. It was also held by the court that a notice of intention to claim a lien for work on the mine or several mining claims operated as a mine, need only describe the mine as a whole or refer to the claims by name or number, without referring to an easement in adjoining lands where such easement was a necessary appurtenant to the mine.

Park City Meat Co. *v.* Comstock Silver Min. Co., (Utah) 103 Pac. 254, June '09.

MINING—RELATIVE RIGHTS OF MINE AND SURFACE OWNERS.

The right of a mine owner to take minerals underneath the surface is subordinate to the right of the owner of the soil or of the surface to have it supported in its natural position; this right is a part of the freehold, and the mining must be exercised in such a way as not to deprive the owner of the soil of his existing rights. Under such circumstances the mine owner cannot establish a custom of allowing miners to destroy the surface support by removing the pillars.

Southwest Missouri R. Co. *v.* Big Three Min. Co., (Mo.) 119 S. W. 982, June '09.

ASSIGNMENT OF MINING LEASE.

The Alaska statute provides that an assignment of a lease of mining property shall be executed with the usual formalities of a deed; but such a lease was not invalid because the subscribing witnesses thereto were members of the partnership which was the assignee of the lease.

Halla *v.* Cowden, 170 Fed. 559, May '09.

COMPANY REPORTS.

LUCKY TIGER

The Lucky Tiger-Combination G. M. Co., with offices at Kansas City, is owner of the Tiger Mining Co., S. A., having properties in Sonora, Mexico. J. W. Malcolmson, consulting engineer, reports that during 1909, 47,130 tons of ore were broken, of which 1911 were shipped to the smelters and 37,721 milled, 2235 tons of concentrate being produced. The ore milled averaged $24.65 per ton. Receipts from ore sales amounted to $1,087,273, of which $586,598 was net profit after deducting operating charges, freight and treatment, interest on bonds, taxes, and some other items. This is $200,000 better than the previous year. Dividends to the amount of $409,500 were paid. Development amounted to 8161 ft., increasing ore reserves 79,445 tons. The total ore in reserve is now 258,891 tons of which 90% is exposed on four sides and the remainder on three. There is 150,000 tons additional of probable ore and 48,000 tons of tailing. The latter has a gross value of $9.96 per ton and may be treated at a profit of $5.94 per ton. The profit from treatment of the tailing will be enough to pay for the proposed new plant. Within the year a drainage and development tunnel 2250 ft. long was started. It will intersect the vein 300 ft. below the lowest workings. A new contract has been made with the A. S. & R. that will effect a saving of $6 per ton in treatment of high-grade ore and concentrate. The company has contracted to purchase 50,000 acres of adjacent land. Plans are under way for increased power and milling plant. In the report no details as to costs are given.

ROUND MOUNTAIN

The Round Mountain M. Co. owns a rich mine of free-milling gold ore in Nye county, Nevada. For the year ended March 31, J. R. Davis, general manager, reported 8098 ft. of development and an increase of 5458 tons in ore reserves, making a present total of 45,360. The value of this ore is placed at '$9 to $10 per ton', slightly below the previous average net return of $11.63. The following figures of costs for the year are of interest:

	Cost.	Cost per ton.
Development	$58,844	$1.738
Ore extraction	78,821	2.318
Milling	51,150	1.510
General expense	11,985	0.353
Total		$5.919

The above figures include a fixed charge for deterioration on all mine and mill machinery, building, and equipment. During the year, the company mined and milled 33,860 tons of ore of an average value of $11.63, with a gross value of $393,865, and a net of $192,805. Miscellaneous earnings were $1244. The total net profit for the year was $194,049. This shows a net increase over the earnings of the year previous of $16,960. The cost per ton was $5.919 as compared with $6.07 the preceding year. Besides paying four quarterly dividends of 4c. per share on the issued stock, amounting to $131,181, the company purchased 531,800 shares of the Round Mountain Combination M. Co. stock at a cost of $16,035; and purchased for 60,000 shares of treasury stock, the Black Hawk lode and three fractional claims. This gives to the company a total of 222 acres of patented ground, and a total of 121 unpatented. During the year the company has added to its mine and mill equipment, new machinery at a cost of $34,188. The total tonnage mined and milled since beginning operations has been 77,500; total mint returns, $916,123; total dividends, $259,082.

CALUMET & ARIZONA

The report of the Calumet & Arizona Mining Co., just issued, shows a healthy financial condition, with assets of $3,428,680. These consist of cash, $813,360; bullion on hand, $1,045,835; ore in stock, $91,000; supplies on hand, $549,777; accounts receivable, $215,146; stock in other companies, $167,500. It will be noted that mine properties and equipment do not figure in this list of assets. The balance sheets shows receipts for 1909 of $5,054,864, and expenditures of $4,241,303. Dividends of $800,000 were declared during the year. The Superior & Pittsburg Copper Co. shows for the year 1909 receipts of $3,454,956, and an outgo of $3,447,650; with assets, estimated similarly to those of the Calumet & Arizona, of $1,069,940. In calculating the value of bullion in both cases the price of copper was assumed at 12½ cents.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

M. A. Newman is here.

G. B. Staeet was in San Francisco.

James Brown is at Douglas, Arizona.

Edgar Newhouse has been in San Francisco.

S. F. Shaw is making examinations in Arizona.

Clarence Woods is now at Tuolumne, California.

P. C. Stoess, of Seattle, was at Salt Lake last week.

Edwin E. Chase is at Butte examining copper properties.

Ernest A. Haggott will be in Arizona and Sonora during May.

Walter Harvey Weed was in Bisbee, Arizona, again this week.

T. Lane Carter will make headquarters at Chicago hereafter.

Bryan K. Morse, of the Constant-Herzig staff, is at Salt Lake.

Edwin M. Clark is spending a month near Nacozari, Mexico.

Masutomo Mayekawa sailed for Japan this week on the *Chiyo Maru*.

E. R. Abadie has moved his office from Los Angeles to Bakersfield, California.

Forbes Rickard has returned to Denver from New Mexico but will be in Arizona soon.

Alex. Imhoff has been appointed superintendent at the San Juan mine, Taviche, Mexico.

William H. Radford has gone to Siberia by way of London, to examine dredging ground.

E. P. Butts has returned from Sonora, Mexico, and has gone to Tuolumne county, California.

C. H. Jones has returned to the Monte Cristo mine, Moctezuma, Sonora, from Douglas, Arizona.

John B. Farish has returned to Denver from San Francisco. He will be in New York soon.

Charles S. Howe will deliver the Commencement Day address at the Missouri School of Mines.

J. D. Hubbard has resigned as metallurgist for the Oriental Con. M. Co., in Korea, and will return to California.

H. C. Parmelee, Western editor of *Metallurgical & Chemical Engineering*, New York, is spending a week in Utah.

W. F. Ferrier, who has been in Washington and Philadelphia recently, attended the Raymond dinner in New York last week.

Arthur W. Jenks is examining a copper property in Ontario, Canada. He will return to Berkeley, California, in a few days.

Weed & Probert have been examining the Shattuck-Arizona mine at Bisbee preparatory to the listing of the stock at Boston.

C. W. Purington has been in New York contracting for machinery to be sent to Siberia. He will be in San Francisco about May 15.

Jules Labarthe, of the Consolidated M. & S. Co., Ltd., Rossland, B. C., has resigned and will go to Yerington, Nevada, where he will have charge of the new smelter of the Mason Valley Mines Co. at Wabuska.

R. B. Lamb, of the C. L. Constant Co., has retired from that organization to become associated with the Proprietary Mines Company of America, offices at 15 Broad street, New York. He is at Elk City, Idaho, at present.

The National Academy of Sciences at its recent meeting elected the following new members: Jacques Loeb, professor of physiology in the University of California; W. A. Noyes, professor of chemistry, University of Illinois; Charles Schuchert, paleontologist, professor at Yale University; D. H. Campbell, professor of botony, at Stanford University, California; John Dewey, professor of philosophy at Columbia University, New York; Forest Ray Moulton, astronomer professor at University of Chicago; Thomas Burr Osborne, chemist of the Connecticut Agricultural Experiment Station, New Haven, and Professor Schiaparelli, astronomer, Milan, Italy.

Ronald Drake died at Riverside, California, April 25. He was the son of Francis Drake and was, himself, a student of mining engineering.

Erick H. A. Nordain died in New York, April 27. He was for some time connected with the Oroville Dredging Co., Ltd., as electric engineer and had recently completed installing dredge machinery on the Nichi river near Zaragoza, Colombia.

The Secretary of the Interior has withdrawn from entry approximately 13,500,000 acres of land in southeastern Montana. It is believed to contain valuable deposits of coal. It has been withdrawn pending examination and classification. The withdrawal is made on the recommendation of the Director of the Geological Survey. This is the largest single order covering coal territory not previously withdrawn, which has been made since Secretary Hitchcock made the original coal withdrawal in 1906.

APRIL COPPER REVIEW

By Misha E. Appelbaum*

During the month of April, copper has gradually sagged until at the close the metal is freely offered at 12¾ delivered in 30 days, equivalent to about 12⅝ f. o. b., New York. The American consumers have a very small supply on hand but as indicated in my last review are pursuing a hand to mouth policy so that the actual buying power is not sufficient to cause any material change in prices. The exports for the month of April are around thirty million pounds and the domestic deliveries should be in the neighborhood of about sixty-five million pounds, and if April production will not show a decrease, there will be another increase in the visible supply. This will offer very little inducement to the American consumers to buy liberally. The outlook is as yet not very promising. It is reported that the Copper Producers' Association intends to stop publishing the monthly statistics. I do not see what difference it will make whether or not these figures are published since the law of supply and demand governs prices, and manufacturers can easily judge from their own business whether consumption is good or bad. The present moment, however, would seem a very inopportune time to stop the publication of these figures lest it should be interpreted to mean that the statistical position is liable to become worse instead of better.

The Nipissing and La Rose companies of Cobalt have just re-elected their old boards. The two directorates now have five members in common. There has been news of good strikes on both properties and in the case of La Rose some sharp market advances. It is conceded now that in course of time there will be a merger of the principal Cobalt mines, with the two mentioned as the nucleus. As lower grade ores are being extracted many economies in operations could be effected by a consolidation.

PUBLICATIONS RECEIVED

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

PORFIRIO DIAZ, PRESIDENT OF MEXICO. THE MASTER BUILDER OF A GREAT COMMONWEALTH. By José F. Godoy. 8vo.; pp. 253; ill.; maps; diagrams; index. G. P. Putnam's Sons, New York. 1910. Price, $2.

The history of Porfirio Diaz is the history of the consolidation of the Mexican people into a nation. His career covers the period from the war between Mexico and the United States down to the present time, from an epoch when disruptive forces kept the country torn and impoverished to the peaceful days of a strong and progressive government bringing prosperity and widening opportunity. He is the greatest Latin American who has ever lived, greater far than Bolivar, greater even than San Martin. He alone, of all Spanish Americans, has demonstrated constructive statemanship of the highest order. It is not often that so many remarkable qualities are blended in a single nature. As a guerrilla warrior he possessed the dash and daring of a Marion or a Morgan; as a campaigner he showed extraordinary powers of generalship; as a politician he has proved himself a leader and controller of men under circumstances which place him in a class by himself. His military exploits have been singularly like those of that other Diaz, the famous Cid Campeador. If one be disposed to doubt the achievements of the Cid it is only necessary to consider the military marvels performed by Porfirio Diaz to be ready to concede that tradition did not exaggerate the prowess of the medieval chieftain. More remarkable, however, than these deeds of valor, has been the power to harmonize conflicting interests and ambitions, and to hold the reins of authority firmly while carrying out his plans for the upbuilding of the nation. It has required an iron hand to do it, and sometimes it has necessitated despotic acts, the virtue of which can be measured only by the good which has followed to the people as a whole. Mexico today enjoys universal financial credit based upon confidence in the solidity of the structure which Porfirio Diaz has created. This is a sufficient answer to the criticisms of his detractors. But for these successes much that he has been forced to do would write him down as a tyrant; instead he stands before the world as a statesman. No petty tyrant ever seeks to enlighten his people; but from the beginning of his political career President Diaz has fostered and promoted education in Mexico. The public school system of the Republic has reached a high state of perfection under his intelligent guidance. He has zealously labored to increase transportation facilities, which develop a people not only industrially, but intellectually also through larger contact with the world. He has scrupulously sustained the national credit abroad, and provided a banking system at home which is a model of excellence. He has encouraged the introduction of foreign capital, until Mexican investments have become a general favorite with financiers.

The time will come when great biographers will find in the life of Porfirio Diaz material for illuminating exposition of the methods of a master-builder of a great commonwealth. That time has not yet arrived. The attempt made by José F. Godoy will add nothing to the lustre of the man he portrays. The book before us is little more than a catalogue of events; it does not interpret the man in his relation to the difficult problems he has met and solved. As notes for a biography the work is useful; as a reference work on recent Mexican history it will prove convenient; but it lacks inspiration. It is always difficult for a contemporary to set forth the deeds of a great man in proper perspective; it is equally difficult for one of his own countrymen to discriminate between the trivial and the important in the life of his idol. The book is at least a reply to recent diatribes which all thinking men had discredited because of the manifest personal animosity which they displayed. In the face of the great work which Porfirio Diaz has accomplished no one can rob him of the honor he has so splendidly won.

HENDY'S HANDY ATLAS OF THE WORLD. Pp. 128, 6 by 8 in. Joshua Hendy Iron Works, San Francisco, 1910.

This convenient little book contains 84 pages of colored maps of the principal states and countries of the world, with supplementary illustrated tables of statistics of areas and population, and, finally, 28 pages of miscellaneous useful tables and information. It is attractive in form, up to date, and full of short-cut rules and tables of equivalent such as the men around mines constantly need to use. It is substantially bound and evidently prepared for use rather than mere show.

TWENTY-FIVE YEARS OF MINING, 1880-1904. A RETROSPECTIVE REVIEW. By Edward Ashmead. Pp. 184, index. The Mining Journal, London, 1909. Price $1.25.

This little volume deals with the flotation of mines in Great Britain and the Colonies during the period indicated in the title, with many statistical tables of production. In a certain sense it is a recapitulation of present day British mining interests, and gives a great deal of information of value to investors, and to all who are concerned in mining.

RECONNAISSANCE OF SOME MINING CAMPS IN ELKO, LANDER, AND EUREKA COUNTIES, NEVADA. By W. H. Emmons. U. S. Geol. Surv., Bull. 408. Pp. 130, ill., map. Washington, 1910.

A timely and valuable report on an area which will attract many prospectors this year.

MINE ACCIDENT INVESTIGATIONS OF THE UNITED STATES GEOLOGICAL SURVEY. By George S. Rice. Pamphlet, reprint from Jour. Western Soc. Eng., Vol. XIV.

An excellent general statement of this new and interesting branch of the Survey work.

CRIPPLE CREEK MINES, YEAR 1910. Pamphlet. Pp. 47. Colorado Springs, 1910. F. H. Pettingell. Price 25 cents.

A summary of reports made to the Colorado Springs Mining Stock Association by listed companies. A convenient and valuable handbook.

MINERAL PRODUCTION OF VIRGINIA, DURING 1908. By T. L. Watson. Virginia Geol. Surv., Pp. 141, ill., map. Charlottesville, 1909.

A convenient handbook giving statistics of production and notes on occurrence and distribution.

PHYSIOGRAPHY OF THE ST. LOUIS AREA. By N. M. Fenneman. Illinois State Geol. Surv., Bull. 12. Pp. 83, ill., maps. Urbana, 1909.

An informing and accurate account of how the industry and history of one area has been conditioned by geology.

TEMISKAMING AND NORTHERN ONTARIO RAILWAY COMMISSION. REPORT ON MINING AND POWER DEVELOPMENT FOR 1909. By A. A. Cole. Pamphlet. Pp. 48, ill. Toronto, 1910.

PRELIMINARY REPORT ON THE MINERAL PRODUCTION OF CANADA, 1909. By John McLeish. Canada, Dept. Mines. Mines Branch, No. 62. Pp. 18. Ottawa, 1910.

GEOLOGY OF THE VICINITY OF THE TUMAMOC HILLS. By C. F. Tolman, Jr. Pamphlet, reprint from Pub. 113. Carnegie Inst. of Washington. Pp. 13, ill., map.

HISTORY OF COAL MINING IN IOWA. By James H. Lees. Iowa Geol. Surv. Vol. XIX. Pp. 521-604. Des Moines, 1909.

A brief and convenient reprint.

REDEMPTION OF THE GREAT VALLEY OF CALIFORNIA. By A. D. Foote. Pamphlet, reprint with discussion, from Trans. Amer. Soc. Civ. Eng., Vol. LXVI.

IRON ORE DEPOSITS OF VANCOUVER AND TEXADA. By Einar Lindeman. Canada, Dept. Mines, Mines Branch, No. 47. Pp. 29. Maps. Ottawa, 1910.

MINING INDUSTRY OF IDAHO, 1909. By F. Cushing Moore. Eleventh Annual Report of the Inspector of Mines. Pp. 137. Boise, 1910.

MINIATURE EXCAVATING BUCKETS

Contractors are so accustomed to considering only maximum handling capacity in connection with excavating buckets that a demand for buckets of minimum capacity is decidedly unusual. In work carried on by the Cranford company in connection with the special foundations of a part of the New York Rapid Transit Subways and some adjacent buildings such buckets were used. About 350 cylindrical steel and concrete piles 14 in. diam. and varying in length from 8 ft. under some buildings to 60 ft. under the subway, have been sunk through earth, sand, and gravel, with stones of considerable size. The piles were constructed by putting down steel shells and then filling with concrete. Owing to the limited headroom and contracted working space none of the usual methods could be used. It was necessary to use $^{7}/_{16}$-in. steel casing in successive 2-ft. lengths, overlapping about a foot. These were driven by means of a hydraulic jack or drop-hammer. This was accomplished without much trouble by using a cap on

Hayward Buckets in the New York Subway.

top of the upper section of the casing, but the removal of the material at first proved decidedly troublesome. Various means of taking the sand and gravel out of the 14-in. shells were tried without success, until the idea of employing a miniature excavating bucket was suggested.

It is quite a stretch, or contraction, of the imagination to picture an excavating bucket, which is regarded instinctively as a pretty ponderous affair, working inside one of these small cylinders, yet the accompanying illustration shows how it was done. The problem was taken up with The Hayward Company, which supplied five Orange Peel buckets each weighing 28 lb. Each of these was 18½ in. high when open and 17½ when closed, 12½ in. diam. when open and 10¾ when closed. They were operated, like the ordinary sizes, with two lines, one at the head of the bucket and the other attached to the bull-wheel. These were carried up to the sheaves of a double block and managed by two men, and they removed all the material successfully. This unusual kind of excavating was necessarily conducted in a succession of stages. After the casing was forced down a few feet by the jack, the cap was lifted off, and the material taken out with a bucket. Other sections of the casing were then placed on top of those already sunk, and the driving was resumed until it was necessary to use the bucket again. If a large stone was encountered it was broken with a drilling bit, which was churned up and down until the rock was broken. The size of some of the pieces of stone brought up by these little buckets, when compared with the size of the buckets themselves, was surprising. After a casing had been sunk and tested to see that it had the bearing capacity required by the Public Service Commission, it was filled with concrete, thus completing the pile. The work was carried on below sea-level in water-bearing material, which made it necessary to keep pumps at work to clear the trench. As the material was excavated from a casing, water filled it to within a few feet of the top. The buckets frequently operated in 25 ft. or more of water, and it is understood that one of them could excavate from 3 to 8 lineal feet of material in a day.

It is apparent that these little buckets are adapted for other classes of work which often cause trouble; such as digging and cleaning wells and handling materials heated in kettles or caldrons. For example, articles thrown into a hot bath could be removed in this way by perforating the blades of the bucket to allow the liquid to drain out. The variety of such uses is conjectural, of course, but the application of a small-scale replica of a large excavating apparatus to such an unexpected purpose as that described above suggests the probability of a considerable field.

COMMERCIAL PARAGRAPHS

Edward L. Dufourcq has moved his office to Rooms C 22-23-24 of the Produce Exchange Annex, New York.

Sidney Carton is on a trip to Mexico and Arizona in the interests of Geo. W. Myers, of the Chrome Steel Works.

The Bucyrus Co. is building an 8-ft. close-connected placer gold dredge to be operated in Burma, India, equipped complete with steel hull.

The San Francisco office of the Vulcan Steam Shovel Co., of Toledo, Ohio, is now at 1106 Metropolis Trust building. W. R. Bassick is Pacific Coast manager.

The Sullivan Machinery Co. announces that its general offices at Chicago have been moved from the Railway Exchange building to the Peoples' Gas, Light & Coke building, 150 Michigan avenue.

A. Leschen & Sons Rope Co., St. Louis, Missouri, advise that they have the contract for constructing an aerial tramway for the Standard plant of the United States Smelting & Refining Co. at Colorado City, Colorado.

M. R. Ritchie, of the Llewellyn Iron Works, has recently made an extended trip through the northern part of Arizona and portions of Nevada. He went in the interests of the New Standard concentrator, and mining and milling machinery in general.

Osgood, Carter & Co. is the name of a new firm formed by S. W. Osgood & Co. and T. Lane Carter. The company will make assays, analyses, and tests of material as well as examinations and reports. Offices are at 627 First National Bank building, Chicago, Illinois.

The name of the C. L. Constant Co. has been changed to the Constant-Herzig Co. Charles S. Herzig is president of the new concern and will have charge of the engineering department. C. L. Constant will have charge of the chemical laboratories. The executive offices and laboratories have been combined at 42 New street, New York City.

The Smith-Emery Co. has been organized in Los Angeles and will have a complete ore-testing plant and assay office at 245 South Los Angeles street, Los Angeles. E. A. Slater is manager and the company is closely affiliated with Smith, Emery & Co. of San Francisco. The property and equipment will cost more than $40,000, and the plant will be in the heart of Los Angeles.

One of the largest hydro-electric developments in this State has just become public with the awarding of a contract to Allis-Chalmers Co. by the Northern California Power Co. for the initial installation of machinery. The contract calls for all the machinery and accessories and will include three 7000-hp. single horizontal turbines with cast-iron spiral casings. The runners are 50 in. diam. These turbines are each connected to a 5000 K.V.A., 6600-volt, 60-cycle, 3-phase alternator.

MINING AND SCIENTIFIC PRESS

"Science has no enemy save the ignorant."

Whole No. 2599. VOLUME 100. NUMBER 20. SAN FRANCISCO, MAY 14, 1910. THREE DOLLARS PER ANNUM Single Copies, Ten Cents.

MINING AND SCIENTIFIC PRESS

ESTABLISHED MAY 24, 1860.

THE steamer *Corwin* sailed from Seattle May 10 bound for Nome and crowded with freight and passengers. For several years this boat has held the record for first arrival at Nome.

THE BILL establishing the Bureau of Mines at Washington has gone to the President for signature. Since Mr. Taft has already expressed approval of the project, it will doubtless have become a law by the time this reaches the reader.

NEARLY FIFTY YEARS ago the MINING AND SCIENTIFIC PRESS was founded. Next week we shall celebrate the event by re-publishing some interesting things taken from early issues, together with other articles dealing with present-day problems.

DEATH, in removing from this world's activities King Edward VII of England, has taken away one who wielded a powerful influence for the world's peace. The sympathy of the whole world goes out to the English people, coupled with the best of good wishes to the new king, George V.

IN one of our earlier issues, Mr. E. L. Allison, in discussing conservatism, was made to pass severe criticism upon Mr. David T. Day in connection with his work on black sands. Mr. Allison has asked us to say that this was far from being his intention and was due to omission of a 'not' in copying a first draft of his letter. This correction we are glad to make.

COPPER PRODUCERS ASSOCIATION figures for April were discouraging. The increase in stock was 18,579,281 pounds. Production amounted to 117,477,639 pounds, a decrease of 2,589,828, but deliveries were also 4,112,231 pounds less, domestic sales amounting to 67,985,951 pounds, and exports, 31,332,403. The total stock of metal, May 1, was placed at 141,984,158 pounds.

CEMENT production, according to figures collected by the United States Geological Survey, increased at least 20 per cent in 1909 and amounted to over 61,300,000 barrels, worth, at 85 cents, approximately $52,250,000. This is a startling proof of the building activity of the year, and it is interesting to recall that, despite predictions to the contrary, the cement output increased even in 1908, when most mineral industries fell behind.

PANAMA and the Canal Zone are to be visited by the American Institute of Mining Engineers this autumn. It is proposed to leave New York early in November and devote three or four weeks to the trip. Cuba and other points in the West In-

dies will be visited. The number in the party is limited to 150 and the probable expense is fixed at $200 each. The members of the Institute will not only see considerable mining in Cuba, but the application of mining methods to ordinary engineering work on the Canal. There are those who hold that an even larger infusion of mining engineering would have benefited the work on the Isthmus.

TEXAS is mainly thought of as an agricultural State, and by many somewhat more narrowly, as merely where 'they raise cain'. Mr. W. B. Phillips has, however, recently compiled figures showing that in the twenty-seven years ending with 1908, the mineral output of the State had amounted in value to $151,676,346. He estimated the output for 1909 at $15,000,000 additional. The Presidio silver mine at Shafter is famous, the El Paso tin deposits show distinct promise, the Plateau zinc properties are now shipping, and the discovery of an adequate water supply has put mining in the Quitman mountains on a new basis.

SAN FRANCISCO is to entertain the American Chemical Society this year, July 12 to 15 inclusive. A special train on the Santa Fe will bring a large delegation of Eastern members, and numerous local excursions are planned. It is possible that the Puget Sound cities will be visited. The Pacific Coast has much to show the chemists that will be of technical interest as well as an unequaled list of scenic attractions. The visitors are sure to have an enjoyable time, but the main benefits will be those flowing from the stimulation of chemical research resulting from the scientific sessions. Germany is our great exemplar in devotion to chemistry, and that Empire is already deriving enormous pecuniary benefit from the development of the chemical industries. It is a current saying that everything used in the laboratories is 'made in Germany' save matches, which are well known to be made in Heaven. While there may be some slight exaggeration in this, it is true that we have much to learn from the Germans.

THE PANAMA PACIFIC EXPOSITION now seems assured. Congress is not likely to resist an appeal for recognition when it comes from a community which supports its faith by raising by public subscription, over $4,000,000 in one day. Such an amount, raised so quickly, indicates a unanimity of sentiment and purpose sufficient alone to guarantee a great exposition. The opening of the Panama Canal in 1915 will be an event of the greatest importance to the whole world. It is fitting that it should be celebrated at the chief city of the Pacific Coast, the region which is most vitally concerned in establishing new and cheaper routes of travel to the East. Every effort should be made to enlist the widest possible co-operation. The mining industry should make an especially good exhibit, since, had it not been for the wonderful placers of California, the whole history of the Coast would doubtless have been radically different. Mining has been the basis of industry in this region not only historically but economically, and it is yet. The present opportunities in mining are not adequately appreciated, and the exposition will afford the Western States an unrivaled opportunity to attract the world's attention. To do this it will be necessary that the men in charge have the confidence of mining men not only locally but throughout the world. They must be men with whom co-operation is easy, and it is not too soon to be thinking of such matters. The United States Geological Survey has found it necessary to abandon all forms of co-operation with the present State Mineralogist, and it would be a fatal mistake to select any such person to invite the world to participate in an exposition of mining and metallurgy. We hold no brief for anyone, but we believe that it is not too soon to insist that the best possible man be selected.

THE GOLDFIELD CONSOLIDATED report for April gives new proof of the greatness of that mine. The total production for the month amounted to 14,918 tons, dry, with an average value of $75.11. The total return was, however, $1,134,800, as 8000 ounces of gold were recovered in the cleaning up of the burned part of the mill. The costs for the month amounted to $16.83, including $4.11 per ton construction cost due to fire loss. The mining cost alone was $4.49. The loss in tailing is given at $2.22. The profit per ton was $56.06 and the total profit, $839,040. The actual value of the ore sent to the mill during the month was $590,000, on which the extraction amounted to $560,000. High-grade ore to the value of $314,000 was sent to the smelters, making the gross actual production for the month $904,000. In development 2582 feet of advance was made and about twice as much ore was placed in sight as was mined during the month. The detailed monthly reports now being furnished are as satisfactory in form as their content is doubtless pleasing to stockholders.

The Carnegie Foundation

The 'disgrace of dying rich' seems likely to overtake Mr. Andrew Carnegie despite really heroic efforts to distribute his wealth in a manner beneficial to the public. Few men who have given largely, have been at such pains to study intelligently the problem of giving and to safeguard the purpose of their benefactions; yet there is serious doubt as to the value of some of Mr. Carnegie's most notable gifts, and valid criticism against others. He has been occasionally unfortunate in the men who have been chosen to administer the funds that he has devoted to public service. The Carnegie Institution at Washington, a great trust devoted to scientific research, and already accomplishing much good, publishes its reports in such limited editions and in such expensive form as to place them beyond the reach of most men interested. It practically operates to conserve science for the select few, rather than to diffuse it among the great masses. The Carnegie Libraries, which so plentifully besprinkle America, have proved a burden in more than one community, and it may be questioned whether it is of benefit to encourage hopes by the gift of a building, in a village where public funds are only sufficient to support the necessary janitor and librarian, and little

or nothing is left for purchase of books. Not every community looks at the matter as sanely as a certain mining town in Colorado. This village, which shall be here nameless, derives its public revenue from saloon licenses. When the women agitated the matter of a Carnegie library it was found that acceptance of the gift would entail providing an additional $1000 per year. This naturally involved another saloon, and the town council, after debating the question, decided that "this would not be fair to the fellows already in business," and so there is no Carnegie library there.

The gift of money for a united engineering building in New York has resulted in the American Institute of Mining Engineers being in debt, and appeals have been made to members to subscribe a fund for the liquidation of the debt. All this has its defense, and a proper one—that the objects are worthy, and that the gift provokes others to help themselves. The Carnegie Foundation for the Advancement of Teaching raises, however, other questions. The administration of the Foundation has recently come under severe criticism for changing the rules so that a teacher is no longer eligible on the basis of 25 years of service alone, but must also show disability. In other words, 'retiring allowances' as a reward of service, give way to pensions to those no longer useful. It is argued that this converts the pension into a charity, and it is suggested that in making this change the Trustees have exceeded their legal authority. To us these matters are of less importance than certain others which have come up since the Foundation was organized.

It will be recalled that the benefits of the fund were not to be extended to teachers in schools having church affiliations, and the resulting spectacle of colleges cutting loose from denominations which had previously supported them, has been a strong tribute to the power of money. The benefits, in any event, to the teacher have been somewhat questionable. Certainly the probability of a 'Carnegie pension' has been used as an argument why men should accept low salaries in the meanwhile, and fear of the pensions drawing away good men has led State universities and other schools to make every effort to obtain 'recognition' by the trustees of the Foundation. It was clearly necessary for the administrators of the Foundation to establish rules defining what is a College or University within the terms of the gift. This task has been taken very seriously by Mr. H. S. Pritchett, the president. As it is being done, it amounts to standardizing American educational institutions. This is a task neither the States, the United States, nor the National Educational Association have ever seriously attempted, and yet it is quietly assumed by a private foundation on the mere authority conferred by wealth. Already grave questions have arisen. The University of Illinois was rejected, and others have been told to mend their manners and their curricula. That there has been need for some more definite standards in educational work in this country may be freely granted without conceding the advisability of giving to a private corporation the power to fix these standards. America has prospered greatly because of giving the exceptional man the freest opportunity. The flexibility of our educational system has been at once the expression of our economic condition and the means of our development. It will become rigid soon enough without artificial aid, and special students have sufficient difficulty in making their way now. Private foundations, however well meaning and helpful in purpose, become harmful when they directly or indirectly usurp the functions of government, and some dollars cost too much to be worth buying.

University of California and Mining

The University of California is celebrating its semi-centennial, an event of large interest to mining men among others. Through its College of Mines the University has profoundly influenced the development of mining technology, and its graduates have directed the development of some of the greatest of the world's mines. The University grew out of a private school opened at Oakland in 1853. In 1860 the site at Berkeley was purchased and the 'College of California' opened. It was for some years supported by private subscriptions, but in 1867 was presented to the State and was given the land and funds set aside by the Federal Government for the support of State colleges of 'Agriculture and Mechanic Arts.' Instruction was at first literary and classical, but when it became the State University, courses in agriculture and engineering were added. Instruction in mining was taken up some fifteen years after the founding of the school. The College of Mines is now one of the most important in the University. It is housed in a beautiful white granite building, the gift of Mrs. Phoebe A. Hearst, dedicated in 1907. It is interesting to note that the buildings of the mining schools of California and of Nevada were paid for with money won from the mines, in the one case by Mr. George R. Hearst and in the other by Mr. John Mackay.

It is men, however, and not buildings that make a school, and California has been fortunate both as to instructors and students. Mr. S. B. Christy is now closing his thirty-first year of service as Dean of the Colleges of Mines, and in geology, at first Mr. Joseph Le Conte, and later Mr. A. C. Lawson, has grounded the men in the study of ore deposits. These men have influenced the profession not only indirectly through their students, but also by their researches and publications. Mr. Christy did much to clear up the difficult problems incident to the cyanidation of gold ores, and more recently has worked upon the influence of the electric current in precipitation. His students have, throughout the world, made records for themselves in research and management. Messrs. Charles Butters, C. W. Merrill, F. W. Bradley, C. H. Munro, W. W. Mein, and J. R. Farrell, to mention only a few, form a group of mining engineers of which any school might well be proud. The training of men who work effectively is the especial province of a school, and, measured by this standard, the College of Mines of the University of California need not fear comparison. We feel sure we voice the wishes of the profession in extending congratulations and good wishes.

The Raymond Dinner, New York City, April 30

"To be seventy years young is sometimes far more cheerful and hopeful than to be forty years old," said Oliver Wendell Holmes upon attaining his three-score-and-tenth birthday, and this thought was no more appropriately used than when it appeared on the first page of the program of the testimonial dinner to Rossiter Worthington Raymond at the Plaza Hotel on the evening of April 30. Dr. Raymond reached his seventieth year of youth on April 27, but the committee gave him three days' grace so as to be sure, and besides Saturday night allowed an intervening day of rest in which to recover. It was a notable event.

The honored guest of the day might have been supposed to be celebrating the passage of not more than the fiftieth milestone, except for the informationed conveyed by the program, and the advertising of the fact by the announcement sent out by the committee. Dr. Raymond looked younger than he did ten years ago, and were it not for the fact that we know they don't, we might be made to believe that in his case at least, the hands of time were turning backward. It was a great gathering of old friends, many coming from considerable distance to pay their tribute to the recognized dean of the mining engineering profession in the United States. From Bethlehem came 'Uncle John' Fritz, several years more than four score, from Chicago came 'Bob' Hunt, from Toronto came B. E. Fernow, from Washington came several, and from England came R. T. Bayliss to award the medal from the Institution of Mining and Metallurgy. The Canadian Mining Institute sent its greeting by its president, and the Mining Society of Nova Scotia confided its good cheer to its vice-president, who struck a windstorm in Boston and had to send the message on by wire.

Dr. Raymond is best known to most of the mining industry through his twenty-seven years of service as Secretary of the American Institute of Mining Engineers. It is conceded that the peculiar success of A. I. M. E. banquets has been the innovation of having ladies present. And they were there on this occasion in numbers. The members of the Institute who did not have, unless for good and sufficient reason, a wife or sweetheart or sister, was properly a pariah and an outcast. The duties of toast-master devolved upon James Douglas, and a better choice for the presiding officer could not have been made. Dr. Raymond was seated at his right and Mrs. Raymond at his left. In front of the toast-master was placed a model of a mining scene, and at a given signal during the evening this opened in the middle, displaying as a mineral deposit, a magnificent silver tea service, commemorative of the occasion, and a testimonial of the love and reverence of Dr. Raymond's host of friends. A unique feature associated with the service was the pictorial representation on each separate piece of some phase or incident of Dr. Raymond's life. On the tray was engraved a view of the Grand Canyon of the Colorado, which he so fondly loves, and beside the view is engraved his poetic tribute to the Canyon, beginning:

"A thought of God on earth expressed!
The silence of His perfect rest;
The patience of eternal power:
The ceaseless change from hour to hour:
Forms in alternate gloom and flame
That bids yet evermore the same,
And do but wear such fitful guise,
Reflected in our human eyes,
Which compass in their human range,
The things that change, or seem to change."

On one of the pieces was engraved the full rigged ship, *The Great Western*, on which in 1858 Raymond, then but 18 years of age, sailed as third mate: on another is a view of Heidelberg, where he studied in 1859; on another is a picture of Raymond himself in his student's garb of Freiberg, where he pursued his studies in 1860-61; another represents him in the uniform of a United States soldier (1861-64). Other pieces show him as Santa Claus with the children, as the orator, and as a man of society. The interior of Plymouth church, which he has attended since boyhood, is engraved on one of the pieces; and, appropriately, the sugar bowl presents vignettes of Dr. and Mrs. Raymond united by a true lover's knot.

The list of speakers looked rather ominous, but Mr. Douglas in his opening address announced that the five-minute rule was in force, and it was generally observed. The responses to the toasts, while thus made brief, were eloquent tributes to the man as a man, a scientist, a Christian, a man of letters, an engineer, a husband, a father, a friend. In introducing the speakers, Mr. Douglas first referred to the false idea of life as represented by one William Shakespeare in the "seven ages" and cited Dr. Raymond as a contradiction of the "sans teeth" condition of the man of seventy. The first speaker was E. Gybbon Spilsbury, chairman of the general committee, who read the letters of regret from those unable to attend. Among them were greetings from Andrew Carnegie, W. B. Cogswell, D. W. Brunton, W. P. Blake, Sam F. Wellman, S. B. Christy, George Otis Smith, and John Hays Hammond. Appreciative applause followed the reading of the telegram from the San Francisco members, and the engrossed testimonials from the British Iron & Steel Institute, and from the Verein Deutsche Eisen Hütte Leute. R. F. Bayliss crossed the ocean to present to Dr. Raymond the gold medal of the Institution of Mining and Metallurgy, and Sorzano De Tejada, presented the greetings of the Société des Ingénieurs Civils de France. The Canadian Mining Institute was represented by its president, F. D. Adams, who testified to the affection in which Dr. Raymond is held by the members of the Canadian society. They felt, he said, that Dr. Raymond was one of those who proved the theory that virtue became a habit after fifty years of practice. Lyman Abbott, pastor of Plymouth church, Brooklyn, wanted to say what he had to say behind Raymond's back rather than before his face, and the back was quickly turned. His tribute was to the man as a help, and guide, and counsellor, and friend to his pastor. The sister engineering societies, the

Civil, the Mechanical, and the Electrical, were represented respectively by John A. Bensel, George Westinghouse, and T. C. Martin. It was Mr. Martin's review of the linking of the electrical with the mining world that showed the debt of the former to the latter for everything but the water in its stock. He spoke of the discovery of the Roentgen rays, the work of Madame Curie in radium, and gasped for breath as he announced that this was a world of rays —a Ray monde. To the hall of fame in mining literature where are placed the names of Mark Twain, Bret Harte, Joaquin Miller, he added that of R. W. Raymond.

W. L. Saunders, chairman of the committee on speeches, had the honor of giving the address to Mrs. Raymond. A portion of his remarks were as follows:

"Lord Burleigh in giving advice to his son, said: 'Use great prudence and circumspection in choosing thy wife, for from thence will spring all thy future good or evil'. Forty-seven years ago was a critical period in the life of our guest: young, able, ambitious, and yet strong in faith and love, he knew that the glory of young men should be their strength, and so towering in the confidence of twenty-three he plucked from the highest boughs this 'flower of wifely patience'.

"The story is told of a man who led in everything. He was the captain of the ball team, the leader in his class, the county chairman, and the deacon in the church. In due course he took to himself a wife, and a friend who knew him well was asked how he was getting along since he married. He always led everyone, and it was said that no woman could ever get ahead of him. 'Oh', said the mutal friend, 'he is still leading, I suppose, but his wife is just behind holding the reins'.

"On behalf of his friends and yours it is my privilege to lay these flowers at your feet.

"Here is a rose for you for every year of wedded life: It lifts its face above the thorns as you have always done—as you do now—

" 'Here mark you, where the bolt of Cupid fell;
It fell upon a fragrant little flower,—
Before, milk-white, now crimson with love's wound'."

In responding to the speeches, letters, and telegrams of felicitation, Dr. Raymond seemed at first and for once in his life at a loss for words. Praise, he said, humbled, while it exalted his spirit, and he wanted simply to say "thank you, thank you, thank you," but for fear that his hearers might conclude that some strange mysterious change was wrought by the turning of a seventieth birthday, he must say something. His sense of gratitude was deep, and more than once the words were choked by the pent-up feeling, and tears were in his voice and in the eyes of more than one who sat before him. He said he was not going to allow a little thing like seventy years to retard his work. He was still in the harness, and he did not restrict his day's labor to eight hours. In the course of his remarks he stated that his life had not been entirely what his early ambition had looked forward to. His ambitions had been overruled, but he had lived a happy—happy life, and he felt that all was for the best.

Coal Mine Accidents and Their Prevention

By J. A. Holmes

*If we are going to attempt seriously to reduce the loss of life and the waste of resources in our mining industries, we must carry on investigations and inquiries to determine the causes and to devise preventive measures; we must promptly and adequately inform the miners and active mine officials of the results of such investigations and inquiries; we must revise our laws and regulations in accordance with the best information thus obtained; and we must look to a proper enforcement by the States of such laws and regulations. We must also go to the tap-root of the evil—that is, we must improve the economic conditions on which this great industry is based.

Our coal industry in its phenomenal growth has nearly doubled during each succeeding decade of the past 80 years. It has had to do more than keep pace with our increasing population, for, while it supplied less than one ton of coal per capita to the American people in 1870, it has had to supply nearly six tons per capita during 1907. Its growth has been too rapid for systematic development; and the industry today represents a great host of scattered, warring, discouraged elements, without organization or co-operation. In this industry are now employed some 700,000 miners, who work at some 6000 different mines and produce yearly about 500,000,000 tons of coal. Not only is the nation increasingly dependent upon this coal for its heat and light and for power for its manufacturing industries and transportation facilities, but this coal and other mineral products now contribute more than 65% of the total freight tonnage of the country. The economic conditions upon which coal mining is based in this country are so fundamentally bad, and the evil consequences are so far-reaching as to both time and extent and are so essentially national in character, that this subject demands the earnest consideration of our best statesmen, as well as of our best engineers.

There can be no permanent industry without reasonable profits. It is unjust and irrational that in this great and essential branch of industry reasonable profits or even the payment of operating expenses should be dependent upon methods involving unnecessary sacrifice of human life and unnecessary waste of resources which we can neither replace nor restore and which will be essential to the larger future development of the country. The following observations will serve to make this situation clearer: (1) In spite of this rapid growth in our demand for coal, the normal productive capacity of our coal mines if operated continuously would greatly exceed this demand. (2) Ruinous competition exists not only between the operators in the same field, but between the operators of one field as against those of another field or in another State where different mining laws and regulations are in force. (3) This competition is, first of all, driving out of the business

*Address delivered, with approval of the Director of the U. S. Geological Survey, at the tenth annual meeting of of the National Civic Federation of New York.

the small operators, except where they find protection under local freight rates, and is forcing even the larger operator to mine coal under conditions which he cannot approve but from which he finds no escape. If he and his fellow operators endeavor to 'get together' and place the price of coal at the mine on a reasonable basis they go to jail under either a Federal or a State statute; and, as the only alternative, each must live (or succumb) by underbidding the other, which he can do only through following the wasteful and unsafe mining methods which prevail in this country today in spite of the desire of every operator to improve them. (4) Even when the demand for coal and the prices are at their best, under existing conditions the operator can mine only that part of his coal which can be taken out most cheaply and sold at the higher prices; and the remainder must be left underground in such shape as may preclude its future recovery. And thus we waste yearly approximately 250,000,000 tons of the nation's fuel supply. (5) The American mine owner is as humane as the mine owner of any other country, and he would like to follow every practice and use every appliance for safety to be found in Great Britain, or France, or Belgium, or Germany, or elsewhere, but he pays his miners higher wages and, at the same time, receives for his coal at the mine half the price received for similar coal by the operator in those countries; and he must employ miners an increasingly large percentage of whom come to him unfamiliar with either the practices of the industry or the language and traditions of the country. (6) The penalty which the nation is paying for this bad system is this increasing waste of essential resources and the still more unpardonable increasing waste of human life—the yearly loss of 250,000,000 tons of coal and the killing or injuring yearly of 8000 to 10,000 men.

The fact cannot be too clearly emphasized that it is the nation that pays this penalty; and that its increasing evil results will lessen the nation's future development. The remedies for this bad situation are: (a) Investigations and inquiries, such as are now being conducted by the Government, as to the causes of mine explosions and other similar investigations as to the causes of mine accidents of other kinds and as to the methods of prevention. (b) The dissemination of information among the miners and the active mine officials as to these causes and remedies. (c) The training of men at each mine as to the best methods of using explosives, using electricity, handling gases and dust, and timbering, preventing and extinguishing mine fires, as well as the methods of rescue work and of first aid to the injured. (d) The development of better, more uniform, and enforceable State mining laws, rules, and regulations, based upon accurate data and experience. (e) Active determined co-operation between the miners and the mine management and the State's inspectors in the enforcement of these rules and regulations, with a view to the maintenance of the safest possible conditions in every mine. This means strict and rational discipline in and about every mine among miners and mine officials. (f) State mine inspectors should have better support in the way of compensation and allowance for travel expenses, greater permanence in office, and freedom from political and other outside influences; and wherever possible their efforts should be supplemented by the employment of special private inspectors by each company.

The above are all parts of the program for lessening and alleviating mine accidents, but they do not complete the program. It is an essential part of this program that: (g) The ruinous competitive systems upon which coal mining in the United States is based at the present time should be changed and that the price paid for coal at the mines should be such as will permit and secure safe and efficient mining—mining unaccompanied by either this large loss of life or waste of resources, mining which can have due regard not only to the safety but also to the health and comfort of the men who toil underground and whose labor is so essential to the welfare of the nation. All this can be done without adding appreciably to the burden of the average American citizen, without any increase in the price of coal at the poor man's cottage, and without the risk of any unreasonable restraint of trade. An increase of ten or twenty cents per ton in the price of coal at the mine would greatly increase the possibilities for safety and clean mining and would not necessarily mean any increase in the cost of power to the consumer, who in many cases could save more than that much per ton by adopting more efficient methods in the use of this fuel. Nor is it believed that large consumers of coal would object to this reasonable increase in price, in behalf of safety, clean mining, and reasonable operating profits, if assured that their competitors would have to pay the same and that the price would be reasonably stable. The injustice of the situation is apparent when it is seen that of the $3 or $6 per ton paid for coal at the point of consumption only $1 goes back to the mine to be divided between the miner, the operator, and the land owner, to cover investments in mine equipment and development, all the labor and costs and dangers of mining operations, and the loading of the coal on the cars ready for shipment.

It is for the law-makers to devise a plan that will permit this needed co-operation among the mine operators in behalf of greater safety for the miner, less waste of resources, and reasonable profit on investments, and that will also protect the public against the possible abuse of this privilege. The coal industry needs and deserves fair treatment at the hands of the American people, and upon the receipt of such treatment depends in large measure not only the welfare of the operators—though nobody cares about *them*—but also the welfare of the 700,000 miners who daily risk their lives in supplying the fuel for the nation's industry and commerce and the heat and light for the nation's comfort and convenience, and the welfare of the industry itself as an essential part of our future national development.

The United States Steel Corporation has been within the last few days curtailing operations to such an extent that it is estimated by steel experts in the Pennsylvania district that the reduction in output amounts to 20% among the blast-furnaces.

Mounds Formed by Mineral Crytallization

Written for the MINING AND SCIENTIFIC PRESS
By FRANK L. HESS

*Twenty miles west of Randsburg, in the Mohave desert, lies a playa or periodic lake known locally as Salt lake. It covers probably between 20 and 25 square miles and is a type of lake bed found at many places in the southwestern desert where the waters from the surrounding mountains collect in fault valleys which have no outlet. Those that flow into Salt lake are collected from the Rand, Lava, and El Paso mountains, at the south end of the Sierra Nevada, and in this drainage basin are a large variety of rocks. Among these are Tertiary sandstones which were probably laid down in water more saline than that of the ocean, as they contain some gypsum. As the waters of the lake can escape only by evaporation, the salts brought in from the surrounding country gradually accumulate. The most prominent on the surface of the lake bed is common salt and from this the lake has received its name. Besides common salt, there are sodium carbonate, sodium sulphate, cotton-ball or ulexite (one of the borax minerals), and gypsum. The common salt is distributed all over that part of the bed of the lake which is wetted by ordinary stream flow, but it is by no means evenly distributed. The other minerals are found only in certain portions of the lake bed or the immediately adjacent land. The lake bed is so flat that the eye can perceive no slope to it.

Near the shore at the southwestern edge of the lake bed, three miles from Cane Springs, are a number of low mounds from 2 to 4 ft. high and from 20 to 200 ft. in diameter (Fig. 1), whose peculiar, evenly rounded appearance attracted my attention during a visit to the locality on December 16, 1909. The water which sometimes surrounds the mounds is probably never over 4 to 6 inches deep. The outside of the mounds is powdery, soft earth fissured with cracks, part of which are parallel to the circumference of the island while the others criss-cross between these. Upon digging into them it was found that four to six inches below the surface there was a layer of white, comparatively pure, hydrous sodium sulphate (mirabilite) three or four inches thick. Below this was a spongy mass of sodium sulphate crystals mixed with more or less dirt. In several other mounds examined, instead of mirabilite the salt contained was sodium chloride (common salt) crystallized in a peculiar columnar form. The effect of its crystallization has been the same in raising mounds as that of the sodium sulphate.

In crystallization, sodium sulphate takes up more than its own weight of water (126.8%) and the expansion is considerable. Evidently the expansion of the salt in crystallization has raised certain parts of the lake bed until they have reached their present height in these islands. Mixed with the mirabilite is about 3% glauberite (magnesium sulphate) which imparts a taste so bitter as to give the impression that the percentage is much higher.

I have described a somewhat similar mound known as the 'Oil Bubble'[1] in the Lost Hills south of Tulare lake in the San Joaquin valley (Fig. 2). The 'Oil Bubble' which stands on the south side of a draw running through the hills, is between 10 and 15 ft. high and about 65 ft. in diameter, and is composed of small crystals of gypsum, most of them less than one-quarter inch in length, mixed with enough clay to permit the mass to be easily kneaded. This mound also contains a small amount of material resembling greatly oxidized asphalt, stained slightly with native sulphur. At the time it was visited the mound was wet and sticky, and it is said to remain moist throughout the summer. It is reported to give off bubbles of gas, whence the name 'Bubble', the supposed asphalt suggesting the name 'Oil'. It is thought that the mound was formed by the evaporation of water carrying gypsum in solution, the clay probably being brought to the place by winds. The excessive dryness of the surrounding country makes it seem probable that the water comes from a considerable depth, rising through the Tertiary gypsum-bearing sandstones.

The most important hydro-electric developments of Canada are at Niagara, where it is estimated 5,000,000 continuous electrical horse-power can be produced. Of this about one-tenth will be utilized when the stations now running are fully equipped. Four stations on the Canadian side can produce about 450,000 electrical horse-power.

Evolution of Well-Drilling Machinery

Written for the MINING AND SCIENTIFIC PRESS
By JOHN L. COWAN

With hundreds of 'strings' of tools drilling for oil in California, the beginning of well-drilling supplies an interesting field for research. Pennsylvania erected a monument last year, commemorative of Drake's exploit in drilling the first oil-well, at Oil City, in 1859; but Drake made use of tools and appliances copied from the devices originated long before on the banks of the Kanawha river, in West Virginia.

Well-drilling machinery is so much a matter of course nowadays that it is difficult to realize that if men wanted to make a hole in the ground a century ago they were compelled to dig it. That was laborious, tedious, and costly; and early settlers in the Eastern States made it an invariable rule to build their cabins close by a spring, that they might escape the toil of digging a well for water. The first well ever drilled was not put down to obtain water, nor in search of oil or gas, but in order to obtain a more bountiful supply of salt water than seeped out upon the surface. The 'salt licks' of the Kanawha valley were worked from the time of the first white settlements west of the Alleghanies, and had been used by the Indians for unguessed centuries before. Herds of buffalo, elk, deer, and other wild animals frequented them for the purpose of licking the salt-impregnated earth. To this fact they owed their name, just as this circumstance led to their discovery. The most famous of all the salt licks of the valley was the 'Great Buffalo' lick, about three miles above the present site of Charleston, near the mouth of Campbell's creek. In 1794, Joseph Ruffner, an enterprising farmer from the Shanandoah valley of Virginia, purchased the land upon which the Buffalo lick was situated, and two years later he leased it to Elisha Brooks. Early in 1797 Brooks began the manufacture of salt from the brine that oozed up through the mud and slime—this being the first manufacturing industry ever established on the west slope of the Alleghany mountains. His 'factory' consisted of 24 iron kettles placed in a double row, with wood fires underneath. The kettles were filled with brine, from which the water was evaporated by boiling. When all the moisture had been evaporated the salt was ready for market. Of course the brine that found its way through the mud was dirty, and the product showed many discolorations and impurities, and it was not long until American inventive genius found room for the introduction of improvements.

The first improvement was to sink huge hollow sycamore logs into the earth. As the brine bubbled up through the logs, it was dipped out in buckets and transferred to the kettles. The brine secured in this manner was comparatively free from sand and dirt, and the salt secured by evaporating this showed great improvement in appearance and quality. The sycamore logs, called 'gums' by the pioneers, were from 8 to 12 ft. long, and 3 to 4 ft. in diameter. They were maintained in an upright position in the soft earth by props and ropes, and were reached by planks laid from the solid ground across the mire. In this rough and ready fashion, Brooks managed to secure about 150 lb. of salt daily, which sold readily at his factory at 10c. per lb. As the only other sources of supply were on the seaboard, involving a long and dangerous trip across the mountains to 'tote' it to 'the West', he experienced no difficulty in disposing of all he could make, his market extending to every settlement west of the Alleghanies from northern Pennsylvania to Tennessee.

In 1803, the elder Ruffner died, leaving his property to his two sons, David and Joseph. At about the same time the term of Brooks' lease expired, and the Ruffner boys refused to renew it. They then began the manufacture of salt on their own account, reaping the benefit of the extensive business built up by the former operator. For a time they contented themselves with following the methods used by Brooks; but they were young, energetic, and ambitious, and desirous of improvement. They reasoned that if they could get below the soft mud and sand through which the brine forced its way, to the true source of the supply, they would be able to obtain it in larger quantities, and that it would be pure and entirely free from dirt. In 1806 they began their labors, and after much difficulty succeeded in getting their 'gum' down to bedrock at a depth of 18 ft., and in cleaning out the slime and sand from the hollow log. As they expected, pure, clean, strong brine slowly welled up through the porous sandstone into the 'gum'. How to penetrate the sandstone, and thus permit the salt water to have free and unimpeded flow, was the next problem that presented itself for their solution. They had observed quarrymen drilling holes two or three feet deep to hold their powder for blasting, and concluded that an adaptation of the same principles would enable them to accomplish the desired result. They, therefore, made a long iron drill, with a 2½-in. chisel bit of steel at the point, and attached the upper end to a spring pole. The motive power was supplied by their own brawny arms. In this tedious and laborious manner the first well ever drilled in solid rock was begun and carried to a successful conclusion. By November 7, 1807, they were 17 ft. in solid rock, when they struck a fissure from which issued a stronger flow of salt water than they had previously obtained. When 11 ft. deeper, another 'pay' was tapped, and in January, 1808, when 40 ft. in the rock, and 58 ft. from the surface, they were rewarded by an ample flow of strong pure brine, and the work of drilling was completed.

The first well through solid rock had been successfully drilled, but now an unforeseen difficulty presented itself. In ascending through 40 ft. of porous and fissured sandstone, the strong brine was more or less diluted by fresh water from nearer the surface, and a certain amount of sand was carried up from the friable rock that constituted the sides of the well, impairing the purity of the salt. In those days steel or iron pipes were unobtainable. Even sheet iron could not be secured, and if it had been there was no one west of the mountains who could bend it and weld it into tubular form. Once more

the Ruffners were obliged to rely upon their own ingenuity. With incredible patience they cut and whittled two long strips of wood into half-tubes. Then, carefully fitting the edges together, they wrapped the whole from end to end with twine, and their long wooden pipe was complete. The 'packing' was made by wrapping twine and old cloths around the pipe to make it as nearly watertight as possible, thus preventing fresh water and sediment and adulterating their supply of brine. In this slow and laborious manner was drilled, cased, tubed, and packed the first well; the work involving the nucleus of nearly every idea later developed into the expensive and efficient machinery first used on a large scale in the oilfields of Pennsylvania, but now employed throughout the world, and used in bringing in the gushers that are directing the eyes of all oil operators to California. Although the Ruffners did not know what petroleum was, they were the real pioneers of the vast industry that depends absolutely upon well-drilling apparatus and machinery.

Early in February 1808, the Ruffner brothers made their first lifting of salt from their new well, and at the same time reduced the price to the unprecedentedly low figure of 4c. per lb. Success begets imitation, and it was not long until the Kanawha valley was filled with salt works, modeled after that of the Ruffners, and supplied with brine secured from wells drilled in the same manner. By 1817, thirty such establishments were in operation, with an aggregate annual production of nearly 700,000 bushels of salt. With these extensive operations came further improvement in the methods used for drilling and operating the wells. The first was devised by a tinner, who deserves to have a monument erected to his memory; but unfortunately his name cannot now be learned. He went to Charleston expecting to do a thriving business making tin drinking cups, pans, and other household utensils. Seeing the great expenditure of time and labor necessary for the construction of the wooden tubes used in the salt wells, he proceeded to fill a long felt want by supplying tin tubes in convenient lengths, and soldering them together as they were lowered into the well.

However, the usefulness of a tin tube was short. The strong brine rusted it quickly, making it necessary to replace it with a new tube in a short time. This may have been all right from the tinner's point of view, but it speedily led to the adoption of copper. The next notable improvement was the introduction of 'seed bags' for packing, instead of the old rags and twine used by the Ruffner's and their imitators. A buckskin bag, open at both ends, was drawn over the lower end of the tube like a sleeve. It was then partly filled with flaxseed, in the space between the bag and the tube. Both ends were securely wrapped and tied, and the tube lowered into the well. The water soon caused the seed to swell, making an absolutely watertight packing at the bottom of the well, preventing the escape of salt water on the outside of the tubing, or the entry of fresh water or impurities from outside into the tubing. The seed bag is still sometimes used for packing oil-wells in some parts of the country, but india rubber is preferred on account of its better lasting properties. For some years the salt water was lifted from the wells by hand, in buckets, until some unknown genius rigged up a more complicated apparatus consisting of a pump, lever, crank, and shaft, operated by a blind horse or mule traveling in a circle. It was essential that the animal be blind. Otherwise he would become dizzy from traveling around and around in an orbit so circumscribed! This was considered a really wonderful stride forward, and held the field until in 1828, when the steam-engine was introduced, displacing bone and muscle in drilling wells as well as in pumping salt water. At about the same time the derrick and the walking beam came into general use in the Kanawha valley.

In 1832, 'Billy' Morris, an unlettered Kanawha driller, invented the slips or 'jars'. This is a long double link, with jaws that fit closely, but slide easily up and down. They are made of the best of steel, are 24 to 30 in. long, or even more, and fitted with a pin and socket joint. They are placed above the heavy 'augur stem' and its cutting chisel 'bit' for the double purpose of relieving the long augur stem from a part of the shock from striking the solid rock, and of delivering a quick cutting stroke. When, as frequently happens, the tools become fastened in the bottom of the well, the 'jars' enable the driller to loosen them by a quick upward or downward jar—hence the name. Deep wells in soft formations of clay or shale may be, and usually are, drilled without the use of the jars, but such operations in hard rock would be impossible. As a public benefactor, therefore, 'Billy' Morris deserves to rank with Whitney, Howe, Watt, Stephenson, and McCormick. He never patented his invention, and, of course, died poor. No monument marks his grave, but he is more deserving of renown than many whose deeds live in bronze and marble.

It will, therefore, be seen that long before Edward Drake drilled the pioneer oil-well on the banks of Oil creek, in Pennsylvania, practically every important tool and appliance necessary to sink a gusher in California today had been forshadowed in the Kanawha valley, in what is now the State of West Virginia; and wells had been drilled, in some cases several hundred feet deep, through solid rock strata. Soon after the day of the Ruffners, many of these wells drilled for salt were 'ruined' by oil or gas or both, contaminating the brine and rendering the salt unfit for use. Not until long after the early Pennsylvania oil-wells had made the first thrilling chapter of the oil industry, did West Virginians remember the traditions concerning oil and gas in the salt wells of the Kanawha valley, and set to work for the development of what proved to be one of the great oil regions of the East.

As part of the improvements that will take place in connection with the Broken Hill city's fire service during the year, it is proposed to install a complete electrical fire-alarm system throughout the city. This has been badly needed for some years past, and will, when brought about, greatly facilitate matters in connection with the turning out on the occasion of a fire.—*Australian Mining Standard.*

Glimpses Underground

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD

The accompanying eight sketches give glimpses of the Cornishman at work underground in the tin mines of the 'old county'. These sketches were

Fig. 1.

made by George Seymour, the first president of the Institution of Mining and Metallurgy, who died in 1896, and are based on his earlier recollections of

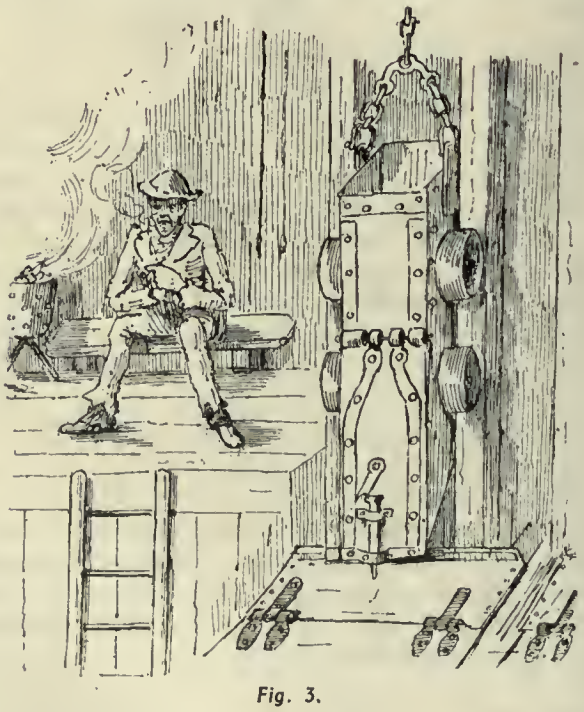

Fig. 3.

Cornish mining, so that they represent an era now past and methods now largely discarded. This must be said lest our Cousin Jack friends should consider these pictures a little libellous in their humorous exaggeration. To Messrs. Bainbridge, Seymour & Co. we owe permission to publish the sketches.

The first shows an important incident of work underground, namely, an interval of rest. These four miners, in two pairs, are breaking their descent on the ladder by having a yarn or 'touch pipe' on their way down. Three of them are on the 'sollar' or platform, while the fourth is on the ladder but resting his elbows on the boards. The drills or 'borers' have been laid asid. The costume of the men includes

Fig. 2.

a linen 'hat-cap' fitting tightly over the head, which is then protected by the hard hat made of resin, to which the candle is attached by a lump of clay. Their

Fig. 4.

clothing is woolen all through. In the sketch the foot-way or ladder compartment of the shaft is shown, contiguous to the rods and pipes of the pumping machinery. A shaft would consist of three compartments, namely, the man-way, the haulage-way for two skips working in balance, and a capstan compartment for moving the heavy portions of the

pumping machinery. The only criticism admissible relates to the ladder, the wrungs of which are too far apart; they appear to be at intervals of 15 inches; 10 inches is admitted to be the best. Moreover, the ladder stands too nearly upright and the shaft is not fenced, as now required by the regulations.

In the next sketch (Fig. 2) we see the pit-men examining the pumping machinery or 'pit-work'. The big pipe is the 'pump-column' through which the water is forced to surface, while the smaller vertical shaft is the pump-rod, which communicates the stroke of the engine to the pole of the plunger. One of the men appears to have something round his neck, and it may be the tressed hemp for packing the stuffing-box of the pump.

Fig. 5.

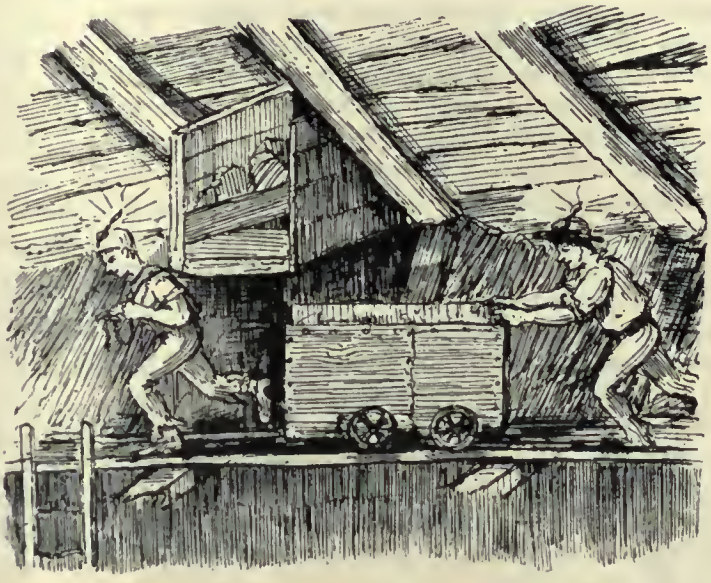

Fig. 6.

Fig. 7.

The 'lander' at surface is represented (Fig. 3) in that attitude of repose attributed everywhere to the man who attends to the tipping and starting of the skip. He is having a 'touch pipe', things are going nicely, and he is rewarding himself with a little comfort. An old kibble or 'devil' is being used to hold the 'cherks' or embers needed to keep him warm. The skip itself is not as large as those at Kimberley, but 't will do, 't will serve. As it comes up the man lifts the door or 'lip', and then drops it again into place; next the skip is lowered and the lander releases the pin at the bottom, permitting the ore to be discharged. Then he rings the bell, the skip is raised, the door is drawn back, the skip is lowered into the mine. The method is rational but antiquated.

Fig. 8.

The predicament of the man on the chain-ladder is obvious; he is ascending from the bottom of a shaft where he has just lit the fuse that will start a blast (Fig. 4). The chain is used because the blast will destroy a wooden ladder. Most engineers have had experiences that will arouse their sympathy for the miner in the sketch. He is a gymnast perforce and will develop the muscles used in rowing. The

chain-ladder is replaced by windlass as soon as the shaft has been deepened. Then he will descend by placing one foot in the bucket while the other is used to stay the gyrations due to the twisting and untwisting of the rope.

In the next sketch (Fig. 5) an even worse predicament is illustrated, for our friend has lost first his candle and then his hat; and he seems to be in a hurry, so we presume that a blast is imminent, or possibly, a 'crush' or 'cave' has started in the winze, for the timbers look unsteady. The artist called his sketch "A scrambly old place."

"Running back from the shaft" is the title of the next (Fig. 6). This shows a 'pass' or chute, by which the ore descends from the stopes. Of the two men, one is pushing, while the other is pulling the truck, which is empty. They are going up-hill. Of course, the underground road-ways are now better kept, but it may be said that in most mines—in Cornwall, as well as elsewhere—the importance of attention to this detail is not sufficiently appreciated.

The seventh sketch represents the men "going to grass," that is, to daylight and to home. Here also the ladder is not quite correctly represented as regards the intervals between wrungs. The first man is carrying a keg, for drinking water, and his 'sling of borers', or set of drills, attached by a chain, which is shown more clearly in the case of the man farthest from the ladder. The miner at the face of the ladder is fingering his clay and adjusting the candle.

Finally (Fig. 8) we have a comical representation of "the sensations of a miner" who has been too familiar with his dynamite. His state is indeed perilous; his cap, water-keg, pick, shovel, and ladder are all in flight, while he himself has received the drill in a vital region. He will never be so careless again.

NEW MINING BUILDING

The mining engineering building at the University of Wisconsin, formerly the heating plant, is nearing completion. Much of the equipment has already arrived. A concrete floor divides the interior into a basement and an upper story, with a gallery and an open mill space at the south end, and the metallurgical furnace in the extension. The basement portion is to contain the crushing and screening room, the ore-bins, supply room, dark-room, and ash-wells. The upper floor is divided into a large assay furnace room, a chemical laboratory, a balance room, two offices, and the gallery on which will be installed the hand ore-dressing equipment and the mining museum. Each student is to have a separate desk which is to be supplied with both air and gas-pipes, and a separate pulp balance for each, while every three students will have precise gold balances, mounted on solid concrete tables. Sinks and fuming hoods, and a lavatory with a shower bath and lockers, are also to be provided for their use. All dust producing operations, so far as is possible, will be confined to the crushing room, where an exhaust ventilating system will keep the air free of the flying particles from the ores. The new plant will be available for next year's work.

MINERAL RELATIONS FROM THE LABORATORY VIEWPOINT

By Arthur L. Day

*The fundamental problems of rock formation, to which petrologists are now giving serious attention, require much more than a perfunctory application of chemistry and physics. The present relations of the minerals in the rocks are accessible to the microscope under convenient conditions of observation, but their development from the fluid magma requires a laboratory study of the rock-forming minerals over a wide range of measured conditions of pressure, temperature, and concentration.

Recent laboratory studies have developed the fact that the temperature of crystallization of a mineral from its own liquid or from a mixture is generally variable and therefore untrustworthy in revealing the conditions of equilibrium during formation. Melting point measurements therefore furnish better determinations of the temperature of change of state. It is also necessary that the methods chosen for such determination be appropriate to the substance under investigation, for minerals are characterized by strong individuality of behavior near the melting temperature, which makes it impossible to apply a single property (the appearance of fluidity, for example) to determine when melting occurs in all substances. The lack of sharpness in melting point determinations is partly the result of carelessness in preparation of experimental conditions, partly of molecular inertia or viscosity which prevents any rapid rearrangement of the molecules of the liquid, and occasionally (in isomorphous mixtures) is due to changing composition during the change of state. The first of these can be eliminated; the second is characteristic of certain minerals and therefore a matter of record; the third is an essential feature of the problem requiring special study. The earlier melting point data offer little evidence upon which to discriminate between these cases. An important factor in rock formation is brought to light by the second of the properties noted above, of which an excellent illustration is found in quartz. In the laboratory, the fusion of pure silica does not occur below 1600° and is accompanied by conditions of extreme viscosity. In nature, vein-quartz appears to have crystallized below 800° and to have been very fluid at that temperature. This suggests that volatile ingredients must have assisted in the formation of natural quartz of which only traces now remain, and its proper laboratory study must include these ingredients. The situation also reveals what is perhaps the chief function of pressure in rock formation, namely, in holding the volatile ingredients in solution.

Bounties to the amount of $40,908 were paid by the Canadian Government from October 1, 1908, to February 18, 1909, inclusive, to the Dominion Steel & Coal Co. and the Nova Scotia Steel & Coal Co. in the form of bonuses on coal used in the manufacture of iron and steel in the province.

*Read before the Geological Society of Washington and abstracted in *Science*.

The Los Angeles Aqueduct Tunnel Work

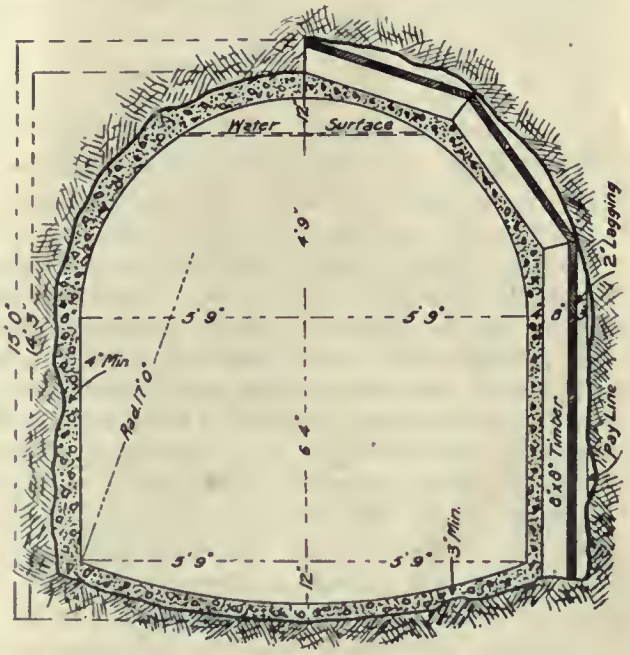
The city of Los Angeles is constructing an aqueduct to bring water from Owens valley to the head of San Fernando valley, whence it will be distributed for domestic purposes and irrigation. The line as finally located includes:

	Miles.
Unlined canal	21.08
Lined canal	152.25
Tunnels in rock	17.24
Tunnels in earth	11.08
Siphons	14.19
Flumes	1.72
Total	217.56

The large amount of tunnel work is of especial interest to mining engineers. Experience which the aqueduct engineers obtained in this work was so favorable from the first that repeated changes in plan have been made increasing the amount of tunnel, decreasing open-cut work, and shortening the length of line. A description of record driving at one of the tunnels has been given by Burt A. Heinly.* Some further consideration of costs and methods may be of interest.

The cross-sections of the various tunnels differ slightly. One, typical of the work on the Saugus division, is shown in the accompanying figure. For this cross-section the excavation amounts to 6.7 cu. yd. per lineal foot where the ground must be timbered, and 5.93 where no timbering is necessary. The concrete used in lining is 1.314 and 1.029 cu. yd. for timbered and untimbered respectively. The capacity of this tunnel is 1000 sec. ft. at a velocity of 7.81 ft. per sec. This section is used, among other places at Tunnel 73. At the long Newhall tunnel, No. 104, a similar but smaller section is driven. For this the excavation is 5 cu. yd. timbered, and 4.12 untimbered; concrete 1.11 and 0.80 cu. yd.; capacity 420 sec. ft., and velocity 4.91. At Tunnel 82 a slightly different section of the same capacity is used.

In the main the tunnels are driven in soft rock, sandstone and cemented gravel being most common. On the Saugus division, the one nearest the city, the ground stands well whether wet or dry. The favorable character of the ground has been an important factor in reducing the costs. While there have been many difficulties, including gas and the inflow of oil, there has been relatively little of the ground which was faulted and moving as in mines and not a great deal of hard igneous rock such as is abundant in mining districts. Much of the work has been done by hand. Frequently the holes could be drilled with augurs and after blasting up to the spring line, the rest was picked down. Some excellent records both as to cost and speed have been made on the Saugus division of which D. L. Raeburn is engineer. At Tunnel 82, with J. T. Nolan in immediate charge, a typical month's record showed: North portal, 399 ft. progress, 399 ft. timbered, unit cost $8.58 per ft. for excavation, $1.32 for timbering; at the south portal the corresponding figures were 434, 424, $7.72, $1.16. For the total work the average cost of the tunnel unlined, was $9.43. The ground here is a compact sand and clay. Three miners work at the breast boring with hand augurs and getting in two rounds per shift of 8 hours, the holes being 3 ft. deep and a round consisting of 6 to 9 holes. Two other miners trim down the sides and pick down the top working on a false staging. Five men shovel, tram, and timber, and there is a foreman for each crew. The eleven men constitute a unit. Miners are paid $3 when working in dry ground and $3.50 when it is wet. The shovelers and trammers get $2.50 and $3. A minimum of 4 ft. is required where the ground does not need timbering and of 3½ where it must be supported. A bonus of 25c. per foot is paid for all above this, the money being divided among the men working in the drift. In practice it amounts to additional compensation to the amount of 75c. to $1 per day per man, but the system greatly increases the speed of the work and decreases the cost. Much the same organization is maintained at other points though where the ground is harder hand-drills are necessary. In the Newhall tunnel, driven in wet cemented gravel, four men work at the breast with hand-drills. At this tunnel one month's progress was as follows: North portal, 176 ft., unit cost $29.36, timber $5.92; south portal, 301 ft., $14.44, timber $6.35. The total progress at that date had amounted to 5572 ft., at a unit cost of $17.65 for excavation and $5.30 for timbering. Concrete lining had been put in 1017 ft. of sides and arch at a unit cost of $5.66 per ft., and in 1075 ft. of bottom at a further cost of $1.91. Tunnel 73, C. B. Worthen, constructing engineer, was driven by hand-drilling through wet shale at the north, and schist at the south. A typical month's work here was: North portal, 168 ft., $18.94; south portal, 126 ft., $26.29. For a total distance of 3271 ft., the unit cost was $26.35. The unit cost of the tunnel complete except for bottom lining was $43.43 per foot.



Cross-Section of Tunnel.

*'A World's Record in Tunnel Driving', Mining and Scientific Press, October 30, 1909.

In comparing these figures the cross-section as well as the character of the ground should be taken into account and it is also proper to state that these are not picked out as representing the best records either as to cost or speed. With these reservations in mind, the following miscellaneous data regarding cost per foot in a number of the tunnels on the aqueduct may be read with interest.

COST OF TUNNELS DRIVEN WITH MACHINE-DRILLS.

Tunnel.	Distance Feet.	Average Cost.	Ground.
12 North	848	$19.34	Hard granite.
12 South	824	21.63	" "
13 North	...	22.93	" "
14 South	...	28.12	" "
15 South	...	22.73	" "
16 North	...	21.66	" "
16 South	...	16.98	" "
17	...	18.31	" "
3 South	774	12.92	Gas in rock.
3 South	1124	14.09	
7 North	1347	14.68	
1 B	1251	9.37	Granite.
3	1014	12.60	"
2	1021	10.57	Wet and blocky.

The above are average costs for tunnels complete, timbered, and ready for lining. The unit figures in each case differ a little from those given but fall within the range indicated. The powder consumption ranges from 4.30 to 39.09 lb. per lineal foot of advance. At the Elizabeth tunnel, November, 1909, using powder of 40 to 60% strength, 17.50 lb. per lineal foot of advance was used at the north portal and 38.09 at the south. This tunnel is driven in hard rock with machine-drills. In the same month at Tunnel 73, 5.80 lb. was used at the north portal and 8.20 at the south. The excavation here is in a soft sandstone and the holes are drilled by hand.

One of the most interesting phases of the work is that of lining the tunnels with concrete. The mixture is 1 to 7, natural gravel and sand being used with portland cement. The latter is in part manufactured at a plant built and operated by the Aqueduct Bureau, and in part purchased on bids in lots of 2000 bbl. or more. The cement costs approximately $1.15 per bbl. when so bought, or $1.45 delivered on the work. It is mixed outside the tunnels in Ransome or similar machines and carried to the work in tunnel cars. The process of lining involves (a) setting the forms; (b) dry-packing where the section has been over-broken; (c) placing the mixture for walls and arch; (d) tearing down the forms; (e) smoothing and plastering the surface; (f) lining the bottom. The forms consist of a series of wooden pannels placed horizontally and fitting against steel ribs. The latter are in two pieces joined by a removable key at the crown of the arch and each extending down to a mud sill at the side. To prevent crowding in, the base of the rib and the sill are braced by sprags against the ends of the cross-ties under the tunnel track. The ribs are made of light T-steel, shaped to conform to the finished cross-section, and are easily placed and removed. Dry-packing with boulders and broken rock is necessary in order to economize the concrete. It is impossible to break a tunnel so as to conform absolutely to a cross-section and leave exactly the calculated space for timbers and concrete lining. One of the difficulties of the work was to train miners not to overbreak the section. In dry-packing the boulders are placed by hand as the pannels in the forms are shipped into place so as to leave as nearly as possible a uniform space for concrete. The minimum thickness of the latter allowed is 4 inches.

In lining the sides the concrete is shoveled from the car directly into place as the panels and dry-packing proceed. To cover the arch it is necessary to have a movable stage. This is known as a 'jumbo' and is a long platform stretching from side to side and supported by legs which straddle the regular track and run on extra temporary rails laid near the foot of the wall. As the work progresses the whole structure moves forward. At the front is a hinged inclined track that can be lowered by means of a motor on the jumbo, and up which the cars loaded with concrete, rock, and panels, may be pulled by an electric hoist. The platform is long enough to permit a full gang of men to work.

After about 36 hours the forms are torn down and the rough places trimmed with small hammers. The surface is then coated, where it is necessary, with a thin wash of cement which is practically a plaster. Later the regular track is torn up and the bottom lined, the work resembling sidewalk laying. Concrete workers are paid $2 to $2.50 according to the character of the work. Foremen get as much as $4 per day. The work here, as in all other departments, is on an 8-hour basis. Under these conditions the concrete costs $5.28 to $8.07 per cu. yd. in place, the amount varying with local conditions and depending somewhat on the relative amounts of arch and bottom work included in each piece of work. The cost for labor and mixing covering complete lining of 853 ft. of Tunnel 20, amounted to: bottom, $2.39; sides, $1.87; arch, $2.85. The total costs on this particular piece of work were:

	Per Foot of Tunnel.	Per Cubic Yard.
Lining bottom	$0.88	$6.72
Lining sides	1.81	6.20
Lining arch	2.79	8.07
Plastering walls	0.31	0.17*

*Per square foot of surface.

The cost for bottom was a little low here, other figures being $1.16, $1.33, $1.91 per foot of advance. Total costs per foot of advance at other places ran, $4.33, $4.54, $5.21, $7.89. These figures are of considerable interest in view of the requirements regarding fire-proofing stations and main entries in coal mines in some of the States, and the desirability of concrete linings for shafts and entries under many other conditions.

Raising is sometimes employed to extend a single shaft driven in the foot-wall in the soft iron ore-fields of northern Michigan. At a convenient point on the bottom level, a winze is sunk in the ore to proposed depth, and from its foot a drift is run to a point below the centre of the shaft. Raising is then started, a chute built, and the dirt handled through the winze, where it is either stored or hoisted from the old bottom level. Ventilation is provided by a small blower.

New Analytical Methods

Written for the MINING AND SCIENTIFIC PRESS
By F. H. MASON

The analyst is always on the lookout for new methods that will facilitate his work without impairing its accuracy, and he will particularly welcome a quick, accurate, volumetric method for determining sulphates, that has a clear, sharply defined end-point. Such a method A. D. Mitchel and Clarence Smith claim to have discovered,[1] and, judging by the results given of analyses of sulphates of ammonium, sodium, zinc, magnesium, copper, and potassium, they have a good warrant for their claim.

Their method, like most modes of determining sulphates, is based on the precipitation of the sulphate by barium chloride. They, however, use a slight excess of the reagent, and determine the excess indirectly by a slight excess of ammonium dichromate, the excess of which, in its turn, is determined by its oxidizing action on a solution of ferrous-ammonium sulphate. The reagents required are a 2n/5 solution of barium chloride, an n/10 solution of ammonium dichromate, an n/20 solution of ferrous-ammonium sulphate, and a freshly prepared dilute solution of potassium ferricyanide, the last for the purpose of an indicator. The indicator is used externally on a white, glazed, porcelain tile in an exactly similar way as in the determination of iron by the dichromate method, and the first appearance of a green tinge is taken as the end-point. In making the calculations, it must be born in mind that, while the ammonium dichromate solution is n/10 as an oxidizing agent, it is n/30 as a precipitating agent.

The analysis is conducted by dissolving the substance containing the sulphate in water, hydrochloric acid, or, if necessary, nitric acid, and precipitating the sulphate by running in, from a burette, a slight excess of the barium chloride solution. The mixture is brought to a brisk boil, neutralized with ammonium hydrate, sodium acetate and acetic acid are added, then slightly more than enough of the dichromate solution to precipitate the excess of barium is run in from a burette, and the mixture is made up to 100 c.c. and allowed to settle. When the solution has settled, 25 c.c. of the supernatant liquid are withdrawn with a pipette and titrated with the ferrous-ammonium sulphate solution, using potassium ferricyanide as an external indicator. Since most chromates are soluble in acetic acid, the method is of wide application. Some, however, such as copper, give a coloration with potassium ferricyanide, which obscures the end-point, but, it is claimed, with practice, a well defined end-point may be found at which the green affects the predominating color. Exclusive of weighings, it is said that five determinations can be made in an hour. In cases where only small amounts of sulphates have to be determined, weaker solutions may be used.

A new method for the detection of caesium, rubidium, and sodium is proposed by Walter C. Ball.[2] Though, at the present stage of his work, Ball only offers the method as a qualitative one, in the case of sodium it has been found of quantitative value. For the detection of caesium and rubidium, Mr. Ball uses bismuth-sodium nitrite prepared by dissolving 50 gm. of pure sodium nitrite in 100 c.c. of water, neutralizing with nitric acid, if necessary, and adding 10 to 20 gm. of bismuth nitrite. The solution is filtered from any residue and must be kept in a well stoppered bottle, as air renders it turbid. As the reagent hydrolyzes by the addition of much water, forming an insoluble oxinitrite, it is necessary to add the solution to be tested to a large excess of the reagent.

This reagent is used as follows: (1) Detection of rubidium: On the addition of 1 c.c. of a 2% solution of rubidium nitrate to 5 c.c. of the reagent acidified with a few drops of dilute nitric acid a bright yellow crystalline precipitate forms immediately. With a 0.5% solution of rubidium nitrate a precipitate occurs in a few minutes, while with a 0.25% solution a slight, easily distinguishable precipitation occurs on standing. (2) Detection of caesium: With caesium the reagent gives a similar precipitate only lighter in color; the reaction, too, is more sensitive, one-fifth of a milligram of caesium in 1 c.c. of solution may easily be detected. Though the reagent does not serve to distinguish caesium from rubidium, in the absence of the heavy metals which interfere and must, therefore, be removed before testing, it serves to distinguish them from potassium, lithium ammonium, thallium, and so forth, which are not precipitated by the reagent. (3) Detection and estimation of sodium: For the detection of sodium a reagent is prepared by dissolving 50 gm. of potassium nitrite, as free as possible from sodium, in 100 c.c. of water, neutralizing with nitric acid, and adding 10 gm. of bismuth nitrite; to the liquid, after filtration, a solution of 10% caesium nitrite is added until the bright yellow precipitate, invariably produced, owing to the contamination of potassium nitrite with sodium, ceases to be formed. The mixture is allowed to stand for several hours and is then filtered, after which more caesium nitrite solution is added until the liquid contains about 2.5 gm. of caesium nitrite. The reagent must be kept as free as possible from air, and if turbid, must be filtered. One per cent solutions of sodium nitrate or sulphate give with the reagent an immediate yellow crystalline precipitate, while 0.5 c.c. of a 0.01% solution of sodium, as nitrate, gives with 2 c.c. of the reagent a precipitate within 12 hours. Thus, it will be seen, 0.00005 gm. of sodium can be detected. Most of the heavy metals interfere and must be removed before testing, but zinc, cadmium, magnesium, barium, calcium, strontium, lithium, thalium, and potassium do not interfere.

In order to make the reaction of quantitative value, it is necessary to know the composition of the precipitate. Results from a number of analyses show the probable composition to be $5Bi(NO_2)_2$, $9CsNO_2$, $6NaNO_2$, which contains 3.675% of sodium. The results of experiments given lend hope that ultimately the reagent may come into use for the purpose of quantitative analyses.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Camping with the Geologists

The Editor:

Sir—The practical mining man is beginning to realize the value of the work of the United States Geological Survey. The 'rock hunters', as the prospectors formerly called them, are the real sort. They are not in the forests, or out in the great wilds merely to 'kill time' and draw pay from a generous government. It is their work to investigate not only the manner in which the evolution of the earth's great surface features has been effected, but, to discover the hidden mineral resources of the country, and present the results of their investigations to mining men in practical form.

On the Winter Trail.

Camping in California

And they do work—these men of the trail, for they are, after all, half-brothers to the veterans of the pick and pan. I was with a party of the geologists for a few days, and for genuine absorption, faithfulness to the task in hand, perseverance, and earnestness, these 'rock hunters' have the most gold-fevered pocket-hunter badly beaten. At 5:30 they are up from beds made of pine boughs, ferns, sand, or hard earth. The early morning air is nearly always crisp, cool, and keen; very keen, in fact, if it be late fall with a heavy hoarfrost whitening the earth, or mid-winter with two feet of snow on the ground. At 6 o'clock the cook's call sounds from the mess-tent, and the men file in and are seated around the temporarily constructed table. The morning repast is no dainty nibble of cookies, cocoa, and toast; it is a hearty breakfast of steaming coffee, wild game, and hot biscuit. At 6:30 the chief of the party gives his orders for the day, stating in detail just what each is to do and where the next camp will be. By 7 all are hard at work. In most sections of the West, where the principal work of the Survey is carried on, there is little difficulty in finding good camping grounds. Everywhere out in the wilds is the cool delightful twilight of the forest, the tang of the fir and cedar, and the sound of babbling snow-melted streams.

When camp is made, space is cleared for the sleeping tents, a wider space for the mess-tent, and a trail opened to the nearest stream or spring. The party is supplied with several pack ponies and saddle horses, to move the outfit from place to place. There are also two extra ponies for the camp cook or the roustabout to use in bringing in supplies. The trails built by the rangers and patrolmen of the Forest Service are proving of great assistance to the men of the Geological Survey, as the latter are now able more easily to penetrate the isolated sections of the far west. Camps of Government surveyors and foresters can now be found near together, and the outdoor life of the two differs but little.

Much of the work of the Geological Survey is the making of the contoured topographic maps, that are now so widely used by mining engineers, prospectors, and locators. These maps are made in the rougher mountain regions and thinly populated areas, on a scale of 1:125,000, or two miles to the inch; in the more valuable and thickly populated areas, they are made on a scale of 1:62,500, or one mile to the inch. Special maps for detailed representation of areas of unusual mining interest are occasionally made on still larger scales. The standard atlas sheet is 20 by 16 inches in size. Sheets made on the two-mile scale embrace an area of between 900 and 1000 square miles, while those on the one-mile scale embrace only 225 square miles.

The Geological Survey intends to be practical: in truth, the results of its labors are intensely practical. The geological map in its final form is a representation of the topography and geology of the area included. The real geological map represents all that

the geologist preparing it knows of the distribution of the rocks occurring within its limits, so far as the scale upon which it is made will allow. Taken in connection with the topographic base, it presents the distribution of the various rocks in the best form for the use of men interested in the mineral formations and resources of the region. To make something even more practical, and to meet the demand of mining men, a second map is prepared, upon which the rocks carrying minerals of economic value are indicated by distinct colors. These maps refer only to the areal distribution of rocks. What is known of the underground geology is graphically illustrated on a structure-section sheet and a sheet of columnar sections. With the four sheets before him, the mining engineer has at hand, in graphic form, a summary of all that the closely observing geologists who prepared it can tell him of the area.

To get the data for these maps, and get them correctly and completely, is as stated, the main work of the men of the Geological Survey. They must endure hardships, and content themselves with the life of men who 'keep close to the soil'. Half-brothers as they are to the prospector, theirs is the genuine freedom of the mountaineer. Difficult and dangerous as is their task at times, they enjoy it, not for the dangers and difficulties themselves, but for the health and vigor and the keen enjoyment of living, and, most of all, for the real love of the work itself.

When the Day's Work is Over.

DENNIS H. STOVALL.

Grants Pass, Oregon, April 25.

Ditch and Flume Information

The Editor:

Sir—I notice in your issue of April 23 'Inquirer' wants to know what size flume he needs to carry 50 ft. per second of water on a grade of 16 ft. per mile. My experience has been that he will need about a 3-ft. flume, 2½ ft. in depth. He will get about 7 ft. velocity, if his flume is well built and fairly straight. In the ditch he will find that water at this velocity will have a tendency to scour too much unless the ditch is in rock. I should advise his reducing the grade along the ditch. The best flume is made by using two 1-in. boards, inside lapping outer crack. This I have found better than 2-in. boards and easier repaired. If the timbers for the setts are in the rough, he should not use anything of less diameter than 3 in. at small end, and for sills not less than 4. If sawed timbers are used, 4-in. square had better be used.

HYDRAULIC MINER.

Granite, Colorado, April 30.

ASSOCIATED OIL COMPANY

*The Associated Oil Co., whose $40,000,000 stock has been admitted to the lists of the New York Stock Exchange, is the first petroleum company listed. Unable to secure better than 12c. per barrel for their product, some forty of the largest producers in the Kern and McKittrick fields, owning 60% of the former and 80% of the latter, incorporated the Association in October 1901 in California. The Southern Pacific company, partly as consideration for funds advanced to provide transportation facilities, secured a controlling interest in 1905. On June 30, 1909, Southern Pacific held $20,069,003 of the stock. Of recently authorized $25,000,000 first refunding mortgage 5% bonds, due January 15, 1930, $10,000,000 have been sold. The company has outstanding, also, $2,746,000 first-mortgage 5% gold bonds, due August 1, 1922, to be refunded with part of the above authorized issue. About $25,000,000 of authorized stock was issued for properties taken over. The remaining $15,000,000, the $2,746,000 first-mortgage bonds, $10,000,000 refunding bonds, and $8,445,979 appropriated from earnings have been employed in construction and acquisition of pipelines and ships, purchase of stocks of other companies, and in development. The Associated owns real estate valued at $25,107,973, improvements and personal property valued at $9,152,648, and $13,769,355 of stocks and bonds, carried on the books at $12,046,837. The chief items under this last amount are $3,500,000 Associated Pipe Line stock, $4,222,461 Associated Transportation Co. stock, and $2,500,500 Amalgamated Oil Co. stock, all par value. These three represent an equity of over $10,000,000 in pipe-line and oil-land properties. In addition the Associated owns 60% of the $2,081,600 stock of the West Coast Oil Co., 90% of the $1,000,000 stock of Recruit Oil Co., controlling interest in three companies with stock of $250,000 or less, one of which paid $300,000 dividends in 1908; a minority interest in seven other companies with capital of $500,000 or less, and owns the $150,000 stock of the Bakersfield Iron Works, which manufactures oil-well supplies, and the $500,000 stock of the Associated Supply Co., a supply distributing agency. Owned and leased fields have the following estimated minimum producing capacity (barrels): Kern River, 526,000,000; McKittrick, 47,233,000; Coalinga, 32,617,000; total, 605,850,000.

*Abstract from the *Boston News Bureau*.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Electro-magnets are now being extensively used in factories to handle castings, and recently a cargo of kegs of nails was raised by this means from a barge that was wrecked in the Mississippi river near New Orleans.

The length of cast in place piles is limited, but piles cast and driven may be of any length. When driven with a core or pipe, the maximum length thus far attained is 45 ft.; no cores have been made longer than this, while the difficulty experienced in pulling the pipe renders a greater length impracticable.

Siphons may often be used to relieve pumps. In the case of a mine pump lifting water to a height of 550 ft., from which point it falls over a cliff 400 ft. high, a siphon will help. Not more than 30 ft. of head can, however, be taken off, since beyond overcoming atmospheric pressure the siphon has no effect. An air-valve must be placed in the crown of the arch, as a certain accumulation of air at that point is unavoidable.

Treatment by caustic baryta and lime is ideal for boiler water for these reagents would remove both corrosive and scale-forming properties. However, the cost of both the hydrate and oxide of barium is at present too great. The reactions that take place are as follows:

$$CaSO_4 + Ba(OH)_2 = BaSO_4 + Ca(OH)_2.$$
$$Ca(OH)_2 + CO_2 = CaCO_3 + H_2O.$$
$$Ca(OH)_2 + CaH_2(CO_3)_2 = 2CaCO_3 + 2H_2O.$$

The present transmission system of the Idaho-Oregon Light & Power Co. in the region surrounding Boise comprises two water-power generating stations, one of 1500-kw. capacity at the Horseshoe bend of the Fayette river, and one of 900-kw. capacity at Barber dam on the Boise river six miles from the city of Boise, together with about 112 miles of high-tension transmission line, approximately one-half of which operates at a transmission potential of 66,000 volts and one-half at 23,000 volts.

Toadstool-like erosion forms have been described by D. B. Sterett as occurring over the outcrop of a batholith of coarse porphyritic granite in York county, South Carolina. Some of the 'toadstools' are ten to fifteen feet high and of similar thickness, and are still firmly attached to the underlying granite mass by stems which may be only one-third as thick as the boulder. The granite also outcrops as floors or bosses similar to the occurrences at some of the quarries of the Piedmont region.

Generally speaking, shafts are 'raised' when a new opening is desired for a developed mine, or when one or two or more shafts, connected by drifts or levels, is to be extended. The method employed consists in driving to a point directly under the proposed opening, whence a small raise is started, which is enlarged later to full size. The muck is dropped into cars on the lower level through a chute, and hoisted through the existing shaft, or used to fill up rooms or workings from which the ore has been removed.

In drying the air for the blast of a furnace by the process developed by F. Daubiné and E. Roy, the apparatus is composed of ten similar and superimposed units, measuring about 10 ft. square and 16 in. high. Each unit has three elements: (1) a grating of water-cooled, externally ribbed tubes, which carry calcium chloride; (2) a series of tubes, triangular in section, imbedded in the chloride and resting upon the grating on one of their edges, through which the furnace gases are passed; and (3) two flat sheet-iron chamber, one at the moist-air intake, and one at the dry-air outlet. The air to be dried is impelled by a fan into a distributing conduit, whence it is distributed among the intake chambers mentioned above and from these chambers it passes to the various units of the apparatus. The air then passes downward through the mass of the chloride, which offers to the air a gradually increasing section. The dried air passes into a collecting chamber, whence it is led to the intake of a blowing engine. Each blast-furnace is provided with four apparatus of the type described. At any given time one is in operation for drying the blast, one is being heated by gases drawn from the furnace to dry the chloride, one is being cooled, and the fourth is held in reserve.

Corrosion of iron is unavoidable. No iron has ever been or ever could be manufactured that would not rust in moist air unless protected by some sort of covering, for the reason that pure iron itself has a tremendous affinity for oxygen and the slightest contact between iron and oxygen in a more or less unstable condition causes the immediate combination of iron and oxygen known as rust. This tendency to corrode is characteristic of the metal itself and is independent of the presence of the impurities it may contain. Iron does not rust when entirely submerged in pure water or water not containing free air; neither does it rust in a perfectly dry atmosphere. The beginning of oxidation is due to the presence of sufficient quantities of free oxygen in the presence of sufficient moisture to act as water of dissociation, this condition permitting the escape of hydrogen and the consequent oxidation of the steel or iron. The great variation which occurs in the rusting of iron and steel is probably due to unequal distribution of the impurities necessary in their manufacture. Iron does not occur in a pure state, and in the process of the manufacture of wrought iron and steel, small amounts of impurities occur more or less unequally distributed throughout the mass. It has been claimed that the small proportion of manganese which steel contains adds greatly to its tendencies to oxidize. This, however, is not borne out by actual experience and the removal of manganese does not carry with it freedom from oxidation. The difficulty lies not in any one cause or element contained in the steel, but in their unequal distribution throughout the steel which permits differences of potential at different points.

Special Correspondence

KALGOORLIE, WESTERN AUSTRALIA

February Production and Dividends. — Labor Troubles at Norseman.—Diamond Drilling.—New Plants.—Tube-Mill Liners.

Progress reports of underground development in our mines show nothing of a startling nature, but steady work is going on as deep as 2650 ft., the present depth of the Great Boulder. The Perseverance is opening as much ground as possible, while its new mill is being erected. The Horseshoe has recovered somewhat from its big drop in January. The South Kalgurli announces its reserves as 156,939 tons at $7 per ton. The February returns from the principal mines were as follows:

Name.	Tonnage.	Value.	Profit.
Associated	10,532	$77,000	$6,200
Associated Northern Blocks	2,285	14,000	4,000
Chaffers	3,746	29,000	4,000
Golden Ridge	2,142	27,000	14,000
Golden Horseshoe	23,109	200,000	45,000
Great Boulder Proprietary	16,297	225,000	115,000
Great Fingall	9,473	71,000	10,000
Hainault	5,705	37,500	7,500
Ivanhoe	18,322	199,500	100,000
Kalgurli	10,020	130,000	57,500
Lake View Consols	10,553	71,000	11,500
North Boulder	810	24,000	15,000
Oroya-Brownhill	20,448	31,500	20,000
Oroya-Black Range	4,300	43,000	9,000
Oroya-Links	10,377	73,000	18,500
Sons of Gwalia	13,505	117,000	50,000
South Kalgurli	9,025	60,500	12,500

The gold output for the State for February was valued at $2,350,000, being a drop of $250,100 when compared with the same month in 1909. Only $13,500 was paid in dividends by the Black Range Mining Co., this being an off month for dividends. There has been some argument as to wages on the Norseman field, some 120 miles south of Coolgardie, and the Miners' Union has rejected the Chamber of Mines offer. The matter will now go before the Arbitration Court. Miners are paid from $2.96 to $3.50 per 8-hour shift, while the average wage for other labor is about $2.96. During the month 37,527,000 gal. of water were used by the Kalgoorlie mines, treating 131,000 tons of ore, this averaging 286 gal. per ton milled, or 1.43 water to 1 of ore. In the February issue of the Chamber of Mines Journal, J. A. Thomson, who is associated with J. M. Maclaren in the geological survey of this field, writes on the effect of certain rocks on the cost of diamond-drilling in Western Australia. The commonest rocks in this State are granites, amphibolites, and greenstones; and the average cost of diamonds per foot in boring these rocks is $1.44, $3.20, and $1.50 respectively. He explains that the reason why the wear of the diamonds is less in the granites and greenstones than the amphibolites is that in the former there is little interlocking of any two minerals and the quartz breaks off in large pieces; but in the latter there is much interlocking of fine-grained minerals, thus requiring more grinding away. The wear is not excessive in the latter, but the rock has a tendency to wear smooth facets on the diamonds, necessitating frequent resetting, making progress slow and costs higher. The amphibolite from the Gwalia Consolidated is quite an abnormal rock. The texture is so dense that the separate minerals can with difficulty be distinguished under the highest powers of the microscope. It is a patchy rock made up of two parts. One is green, made up almost entirely of interlaced hornblende. The other is gray, and apparently made up of a fibrous felt of zoisite. Much diamond-drilling has been done here, but many points have never been satisfactorily explained. For example, why when a drill is set at a certain angle, does it invariably turn at right angles to the dip of the country, rather than cut along it? The Associated company is now doing exploratory work with the diamond-drill. Development work is going on at 2000 ft. The Associated company has ordered an exhaust turbo-generator, to be driven by the exhaust steam of the present steam-engines and compressors. Motors will be installed for driving mills, furnaces, pans, agitators, and other machinery, and a large saving is expected to be the result. Two more Krupp ball-mills are to be put in at the new mill of the Perseverance. The burned furnace shed has been re-built, the ore-bins are well under way, the ball-mill foundations finished, and erection of mills being proceeded with. Ball-mills are easily put together. I have seen a No. 5 erected in 24 hours. The Great Boulder company is installing another Griffin mill, and one duplex Edwards' roaster, making 13 of the former and 3 of the latter type. At the Golden Horseshoe, it is proposed to add 20 stamps, while those in the old 50-head mill will be entirely renewed and the crushing weight of 170 stamps brought up to nearly 1300 lb. each. At present four more tube-mills are being erected in the 100-head mill. The liners being used in the

Cassel Plant at the Lake View Consols, Kalgoorlie.

Part of Consuls dump on the left; that of Great Boulder on the right; electric road of the Perseverance near the Cassel plant.

mills running are of corrugated steel, the plates being some 36 by 10 in. and 3 in. thick at the widest part of the corrugation. Some of these have been in use for nine months, with little wear, and seem good for two years or more. It would seem that such shaped liners would have a tendency to tumble the pebbles about more than the ordinary smooth ones. This is a much desired point in tube-milling. The plates are of some special German steel, and are expensive. The Lake View Consols is also about to use these liners in the new tube-mills being installed, to take the place of some that have been running over nine years. The mill manager thinks these corrugated liners will crush better, but will take more power. More attention is being given to increasing the efficiency of many of our milling plants of late, and some interesting notes should be procurable.

TORONTO, CANADA

Shipments for First Quarter.—Porcupine Isolated.—Camel's Back Lake Rush Over.—Dominion Steel & Coal Corporation.

A comparison of Cobalt shipments of ore for the first quarter of the year shows a small decrease, the figures being 6911 tons for the present year and 7076 tons for the corresponding period of 1909. This, however, only applies to Cobalt proper, the difference being more than made up by Gowganda and Elk Lake output for the three months, of 324 tons. Moreover, bullion to the amount of 78,500 oz. has been sent this year from two plants, the O'Brien and the Buffalo. When the fact that during the earlier months of the year many plants were delaying, or limiting production while waiting for power, is taken into consideration, the showing is by no means an unfavorable one. This circumstance, moreover, sufficiently explains the absence of new shippers from the list of eighteen mines contributing to the output. The only strictly new producer represented was the Waldman with 32 tons, the Hargrave which figures on the list with a 20-ton consignment, being practically in the same category, as it is three years since its former shipment. The Crown Reserve report for the quarter ended March 31, shows ore shipped to a total net value of $380,849, and a net profit on operations amounting to $287,267.

Out of this dividends amounting to $265,322 have been paid. The surplus on hand was $571,221. The capital of the Gifford has been increased from $15,000 to $250,000. W. G. Trethewey, one of the pioneers of the camp, has again taken up active work, having assumed control of the Dominion Cobalt Mining & Development Co., which holds a location adjoining the North Cobalt mine. The Porcupine gold camp has been practically cut off from the outer world for a time owing to the unusually early spring and the breaking up of the winter roads. This, of course, seriously interferes with development and Frank Cochrane, Minister of Mines, to prevent hardship has extended, until June 15, the time in which the 30 days' assessment work must be done on claims staked between January 1 and March 15. Early in the month sensational reports of rich finds of gold at Camel's Back lake, north of Sesikinaka lake on the Temiskaming & Northern Ontario railway, hired several hundred prospectors to undertake the journey only to return a few days later disillusionized. The blame is laid on E. E. Jones and A. Blackburn, two prospectors who started the rush and sold claims for $2000. They are under arrest at Haileybury charged with perjury and fraud. Progress is being made in the direction of the long contemplated Dominion Steel and Dominion Coal merger. The directors of the two companies have prepared a proposition to submit to the shareholders. A holding company to be styled the Dominion Steel & Coal Corporation is to be organized, which will take over the common stock of the shareholders of both companies at par and in addition pay them $4 for each share in quarterly installments. The plan is understood to meet the views of the larger shareholders.

WASHINGTON, D. C.

Mine Inspectors for Alaska.—Investigating Committee Hearings. — Changes in the Mint. — Surveys in Land Grants. — Mine Rescue Stations.

The House Committee on Mines and Mining is in the midst of a hearing on the bill of James Wickersham, delegate from Alaska, which seeks to provide four mine inspectors for the territory. Mr. Wickersham, Lewis P. Shackleford, of Juneau, Alaska, attorney for the Treadwell Mining Co., and Wilford B. Hoggatt, former governor of Alaska, were most interesting witnesses. Mr. Wickersham made the statement that in event of war, it would be necessary for naval vessels on the Pacific Coast to obtain their fuel supply from Alaska, as there was no coal west of the Mississippi river of such high grade as that in his territory. He also referred to the recent disaster in the Treadwell mines as showing the necessity for some sort of inspection. The number of men killed in that accident, he said could not be learned owing to the lack of mine inspectors. He had a letter from a miner to the effect that from 24 to 65 men had been killed in this one accident, and that between 30 and 40 had been killed in separate accidents from January 1, 1908, to date. He estimated that 20,000 miners in Alaska needed this inspection. Mr. Shackleford, representing the Treadwell company, declared that Mr. Wickersham had exaggerated the number of deaths at the Treadwell mines; that they were not more than six a year, and that but 39 were killed in the recent accident. He favored inspection of mines and suggested that the supervision of such inspection be lodged with the United States Geological Survey, or with the Bureau of Mines. Mr. Hoggatt, the former governor of Alaska, who is a mine owner in the territory, also asked that the Geological Survey or Bureau be placed in charge of the inspection, objecting to the provision in the Wickersham bill that the President appoint the inspectors. "We must have fair inspection," said Mr. Hoggatt. "Our mines are of low grade and the margin is very small. In one of the mines, on Douglas island, the margin of profit three years ago—I have not seen the report since—was 14c., and there were 250 men employed in that mine. Now, a burden which would wipe out that 14c. would put out of employment 250 men." Asked about the placer mines in Alaska, he said: "Well, the placer mines are fast disappearing. There is practically no placer mining at Nome now, excepting the dredging and hydraulic mining. In two years from now the drift mining in the Fairbanks country will be a thing of the past; unless we find new camps there will be no such mining in that country. We will probably find new camps, as there is a tremendous area of gold-bearing gravel." The committee decided to leave further consideration of the bill to a sub-committee of five.

At the investigation into the Forestry Service and Interior Department, Alfred H. Brooks, in charge of the Alaska investigations of the Geological Survey, told of the probable length of time the coal supply of the United States would last. He declared that at the present rate of consumption it would require 4913 years to exhaust the supply. These figures were arbitrary, he said. Figured on a basis of the increasing consumption Mr. Brooks said it had been estimated that the supply in the United States would be exhausted in from 100 to 150 years. Somewhere between the 150 and 5000 years he declared, the truth would be found. Mr. Brooks told the committee he thought there had been too much alarm as to the exhaustion of the coal supply. Adna Johnson, of Ironton, Ohio, member of the committee of the House on Coinage, Weights and Measures, has reported a bill which seeks to save $30,000 a year in the weighing of silver coins. The old law requires that in adjusting the weight of silver coins the following deviations shall not be exceeded in any single piece: In the dollar, the half and quarter dollar, and in the dime, 1½ grains. This stands in the amendment, but the following clause is stricken out, "And in weighing a large number of pieces together, when delivered by the coiner to the superintendent, and by the superintendent to the depositor, the deviations from the standard weight shall not exceed 0.02 oz. in 1000 dollars, half dollars, or quarters, and 0.01 oz. in 1000 dimes. The Director of the Mint declared that under the old law three separate weighings of the coins was necessary, two by machinery and one by hand. The committee has reported the bill favorably. Mr. Johnson has introduced another bill which provides that the standard troy pound of the Bureau of Standards shall be the standard troy pound of the mint. The House has just passed a bill appropriating $500,000 for the survey of public lands lying within the limits of land grants, and to provide for the forfeiture to the United States of unsurveyed land grants to railroads. Thomas H. Carter, Senator from Montana, has introduced a bill providing for agricultural entries on coal lands. Frank Mondell, from Newcastle, Wyoming, has introduced a bill to appropriate $200,000 for the establishment of 11 additional mine rescue and experiment stations.

MEXICO

Railway Extensions. — Casados Mill. — Lucky Tiger Report. — Palmarejo & Mexican goes to Oceana Con.— Plomosas Zinc. —Pinguico Mines.

State governments of Mexico are manifesting a willingness to guarantee a reasonable rate of interest on money invested in branch railroads to open and develop territory, and this promises to result in a number of important mining districts securing transportation facilities within the next few years. Heretofore Mexican States have almost invariably assisted in the construction of important railroad lines by the granting of subsidies, but the interest guarantee is more attractive to investors, as a return on the investment is assured from the start. The government of the State of Durango has just granted to Francisco Neugebauer a concession for a railroad from the terminus of the International railroad, a merger line at Tepehuanes to the Guanaceví mining district, and a feature of the concession is a guarantee of 6% interest for a period of 25 years. The State of Zacatecas has arranged a renewal of a concession for a railroad from Camacho, on the El Paso-Mexico City line of the National Railways to the Mazapil mining district, and in connection with the renewal has guaranteed 5% on the mortgage bonds to be issued to provide funds for construction. Foreign capital will be interested in the building of the Guanaceví line, and some of the most promising mineral territory in Durango will be opened. Guanaceví is one of the famous old districts of that section of Mexico, and several foreign

concerns are now operating there. The Madero interests of Monterey and Torreon, controlling the Torreon custom smelter, have the concession for the Zacatecas railroad, and it will be financed through the Franco-Español Bank, of Paris and Madrid. The railroad will have a total length of about 150 miles, consisting of a main line from Camacho to Mazapil and a branch to the Bonanza camp, where the American Smelters Securities Co. is the principal operator. At present the Mazapil district's only outlet is over the Coahuila & Zacatecas railroad, a line extending from Concepcion del Oro to Saltillo, owned and operated by the Mazapil Copper Co., the principal concern of that portion of Zacatecas, the Coahuila capital. The Mazapil company, which is an English concern, has a copper smelter at Concepcion del Oro and a lead smelter at Saltillo, and is credited with a production of about ₱5,000,000 annually. It is expected to start construction out of Camacho before June 1.

Plans are being drawn by Mexico City engineers for a 225-ton reduction plant at the Casados mines of the Consolidated Mining Co. in the Hostotipaquillo district of Jalisco. The plant will be built in units of 75 tons each, and it is expected to have the first unit in commission by December next. The plant will be completed next year. Treatment will be by concentration and cyanidation, the ore passing from 1250-lb. stamps into cone-classifiers and then over Deister concentrators. It is expected to recover 45% of the assay value by concentration, giving a product worth from ₱1200 to ₱2000 per ton. The product of the

Chinipas, Chihuahua.

tube-mills will pass over Deister slimers before being discharged into the solution tanks. The Casados are among the big properties of the Hostotipaquillo district, and are notable among the mines of that district for the high percentage of gold in the ores. They have been under development by the present company during the last three years, and returns from high-grade ore shipped during development are more than covering present expenses. The ore in sight is estimated at over 200,000 tons. W. R. Ramsdell, who is at the head of the Casados enterprise, is one of the principal American operators of that section of Mexico.

The annual report of the Lucky Tiger Combination Gold Mining Co. shows that the rich El Tigre gold mine in Sonora produced $1,087,273 during 1909. The profit amounted to $586,597, and the dividends paid out of the profits to $409,500. During the twelve months 8161 ft. of development was accomplished, making a total of 34,759 ft., which has resulted in placing in sight ore estimated at 257,000 tons. The company is now developing at the rate of 70,000 tons annually. The question of power for the mine and for reduction machinery is still unsettled. The Mexican Union Railway Co., Ltd., of London, has acquired the Torres & Prietas mineral railroad and concession from Mrs. Myra T. Seymour. The line is narrow gauge, extending from Torres, on the Sonora railway (Southern Pacific) to Represo, a distance of 27 kilometres, and the concession gives the right to build to a connection with the Yaqui river line of the Southern Pacific. The London company plans to open important mineral territory by the construction of this extension.

It is reported from London that the Palmarejo & Mexican Gold Fields, Ltd., has entered into an arrangement with the Oceana Consolidated Co., Ltd., now operating in South Africa, by which the latter will acquire control of the Mexican enterprise, and as a result erect the proposed new reduction plant at Chinipas, Chihuahua. A plant with a capacity of 300 tons per day is planned. Engineers of the Oceana company will come to Mexico soon in connection with the projected plant and future development. Belief is expressed that after entering Mexico the Oceana company will not confine its attention to the Palmarejo. It now appears that the option of the Exploration Co., Ltd., of London, on the Buena Tierra lead-silver mine in the Santa Eulalia district of Chihuahua will result in its purchase at a high figure. The mine is owned by the Santa Eulalia Exploration Co., an American concern, and is one of the big mines of that productive district. Pinchon, Durand & Co., bankers of Paris, are negotiating for the Piomosas zinc mines of José Lago in Chihuahua. The price is stated to be ₱400,000, and the deal is said to be certain. El Rayo Mines & Development Co., of the Santa Barbara, near Chihuahua, is paying a quarterly dividend of 4%. The Pinguico Mines Co., of Guanajuato, has paid a semi-annual dividend of 6% ($60,000) on its preferred stock. From a new ore-shoot opened at the seventh, eighth, and ninth levels high-grade ore is being shipped; some carloads having a value of ₱10,000. A report shows that during the 10 months from May 1, 1909, to February 28, last, the Pinguico mine produced 64,609 tons of ore, resulting in a gross revenue of $735,649, but with a net profit of only $257,858.

AUSTIN, TEXAS

Plateau Zinc.—Shafter Silver Mines. — The Quitman Mountain District Finds Water.—El Paso Zinc.

There is a large amount of development now going on in the Plateau zinc mining district. The Texas Zinc Co., the Lone Star Co., the Buck Mining Co., the Howard Mining Co., and the Reed Mining Co., are all working. A recent shipment of five cars of ore from this district to the smelter gave an average return of $800 to the car. It is stated that assays of the ore give an average of 60% zinc. The Plateau Concentrating & Mining Co., recently organized with a capital stock of $250,000, is preparing to develop its zinc claims. Some work has already been done, and it is stated that a considerable tonnage of high-grade ore is in sight. The conditions are so favorable that the company will erect a concentrating plant. Young Brothers and associates who own the Last Chance mine, situated in the Shafter district, are rapidly developing that property into a large producer of silver. It is stated that more than 2000 tons of ore are now on the dump, and that several thousand have been blocked. The vein has a width of 20 ft. at a depth of 100. It is planned to erect a mill and install other machinery. The water supply is abundant and the conditions for working the property are said to be highly favorable. A zinc claim in the Shafter district, owned by J. C. Driffel, is being developed. William Crosby, of El Paso, recently purchased an interest in the Lula B. mine, in the Quitman mountains. An adit is being driven. It is now about 125 ft. long and is in mineralized rock. The recent development of a fine flow of water by the Southern Pacific in a well at Etholin station in the Quitman mountains, is regarded as important. Heretofore the development of the claims has been retarded by the lack of water, and the general belief was that none could be found within reasonable depth. Steps have already been taken by a number of mining companies to sink wells. The shaft that is being sunk on the Tamma silver mine in the Quitman mountains is said to be in good ore. The mine is owned by John Moffitt of El Paso. A rich shoot of high-grade copper sulphide was recently encountered in the Little Lightning mine, owned by John Gilcrease, also in the Quitman mountains. It is reported that the El Paso Tin Mining & Smelting Co. will erect a 50-ton dry-concentrating plant at its tin mine on Franklin mountain. A large amount of ore is blocked out. S. H. Chauvenet, of Sheridan, Pennsylvania, is president of the company, and W. E. Koch, of El Paso, general manager.

GOLDFIELD, NEVADA

Consolidated Builds Power Equalizer. — Florence Goldfield for April.—Discovery on Ford Lease.

At Jumbotown, a collection of buildings near the Clermont and Laguna claims, the Consolidated Mines Co. is now preparing for the installation of a power equalizing station, with storage batteries of large capacity, the installation to involve the expenditure of $30,000. Specifications call for a plant of 2000-hp. capacity. At this point is situated the transformer station from which electric power is sent to hoists at the Clermont, Mohawk, Red Top, and Combination shafts, as well as to the central compressor-plant. The Consolidated company is now using 1000 hp. at the mines and mill, from the Nevada-California Power company's line. Structural steel and other materials to be used in reconstructing the damaged part of the mill are arriving. The time to elapse before the plant is again operating at full capacity is now contingent upon the promptness with which the requisite new equipment is delivered. Another ore-shoot of excellent proportions has been exposed on the 900-ft. level of the Clermont. High-grade ore, chiefly from the 750-ft. Clermont workings, is being shipped to the smelters. The company's normal earnings of approximately $700,000 monthly will be maintained. In the last report of the secretary it is said that the loss by fire did not exceed $125,000. The financial report for the quarter ended March 31, accompanying dividend checks for 50c. per share paid on April 30, shows gross receipts for the quarter of $2,162,282, disbursements $603,496, and net receipts $1,558,786. On January 31 dividend No. 6 was paid, amounting to $1,779,549, and on March 31, the company's cash balance was $2,189,248. After the payment of dividend No. 7 on April 30, also 50c. per share, the company had more than $1,000,000 in cash in its treasury and officials say there is no reason to doubt that the dividend for the current quarter will be paid.

According to reports of the managers of the Florence Goldfield mine the output treated in April approaches 160 tons daily and a recovery of 95% of the gold content is being maintained. This is the largest tonnage ever handled by the Florence. The main shaft is being enlarged to two compartments and manway from a depth of 530 ft. to the surface and with the completion of this work several good ore-shoots that heretofore have been exposed only above the 350-ft. level will be explored from the bottom of the shaft. The long drift to the north is now entering the productive area of the old Reilly lease on the 350-ft. level where a raise will be driven shortly to connect with the old workings. Stopes of large size are now being opened in good ore at the southern extremity of the main workings, in ground formerly embraced in the Little-Florence and Rogers leases. In the latter an excellent orebody was developed by a winze to a depth of 570 feet.

The most important discovery of record on territory of the Merger Mines Co. has been made in the past week on the Ford lease, embracing the original St. Ives shaft and workings. During the past year several shipments of good ore have been made from the 150-ft. level and the ore-shoot has now been penetrated on the 250 and 350-ft. levels. Assays of over $100 per ton had been secured at the 250-ft. level for over a week when the drift exposed 2 ft. of ore averaging from $150 to $200 and accompanied by seams on the footwall carrying as high as $1000 per ton. The appearance of the vein on the 350-ft. level is also encouraging. This ore-shoot was exposed by the original St. Ives company and was followed to the boundary line of the Algae fraction, owned by the Velvet Mining Co. before the consolidation. Work was abandoned by the St. Ives and the drifts were permitted to cave. The Ford lease extends across the Algae and the lessees were forced to drive through some caved ground to reach the ore. They are now sacking ore sampling over $100 per ton and will proceed to open the vein on the 450-ft. level. The 550-ft. shaft of the Codd lease on the St. Ives will be sunk to a depth of 1000 or 1200 ft. The upper levels of this lease have produced some rich ore from a narrow vein.

JOHANNESBURG, TRANSVAAL

Rand Mines Ltd.—East Rand Proprietary.—Low Working Costs.—A Technical Debate. — Equipment Expenditures. — Mine Ventilation.

The chorus of chairman's addresses and the deluge of annual reports continue to dominate the field of events. Facts and happenings give way to opinions and promises. At the same time company meetings as a whole have been unusually interesting, and the majority of chairmen have seized the opportunity of touching upon important questions of general concern, beyond the commonplace limits of a revival of stale statistics. The two most important meetings of the year—those of the Rand Mines, Ltd., and the East Rand Proprietary—were held on the same day (March 23). The subsidiary producing companies of the Rand Mines yielded over one-sixth of the Rand's output and made working profits aggregating £2,367,000 during the year 1909. G. E. Webber summarizes the annual results of the group, the best first-row deep-level mines of the Rand, as follows:

Development footage for year	132,657
Tonnage in reserve at end of year	14,507,186
Tons mined	4,145,785
Assay value of waste rock	0.543 dwt.
Tons crushed	3,651,084
Grade before crushing	7.783 dwt.
Average extraction	95.324%
Average yield per ton: mills, 5.089 dwt.; cyanide works, 2.330 dwt.; total	7.419 dwt.
Average value per ton	31s. 1.7d.
Average working costs: mining expenses, mining 10s. 6.96d., developing 1s. 8.62d., total 12s. 3.58d.; production expenses, 4s. 6.77d.; general expenses, 1s. 5.63d.; grand total	18s. 3.98d.
Average profit per ton	12s. 9.74d.
Total profit from current ore	£2,338,834
Total profit from accumulations	28,320

Upon the East Rand Proprietary Mines, Ltd., a year of excellent work was achieved, and the promise of improvement is substantial. Briefly, the most important results were as follows: Ore reserves, 11,371,761 tons: ore mined, 2,141,872 tons; sorting percentage, 14.37; ore milled, 1,830,280 tons; yield per ton, 29s. 2.3d.; cost per ton, 15s. 5.2d.; working profit, £1,259,057.

On the much debated question of low working costs per ton milled, Sir George Farrar made one emphatic remark demanding quotation: "I see no reason why your company should not always have the minimum cost that it is possible from time to time to attain; and, as I have frequently pointed out, minimum working cost means maximum possible profit per ton, maximum possible life, and consequently maximum profit per claim." The inwardness of this statement may not be quite clear. It is far from a platitude, but constitutes a deliberate statement that while 'costs per ton milled' have been reduced, the greatest total profit has not been a neglected consideration. At the meeting of the Rand Mines, R. W. Schumacher stated on the same day: "Low working costs are undoubtedly desirable as long as they are perfectly legitimate, but they are entirely subservient to the desirability of making the maximum profit per claim treated," and later, "Mr. H. F. Marriott has prepared certain tabular returns which will be filled in every three months, and show the working costs and results at crushing mines on the basis of the superficial square fathom extracted." At a dinner given by Lionel Phillips on March 23, Mr. Marriott was given an opportunity to explain fully the new scheme of returns, with the square fathom as the unit in place of the ton milled. Unfortunately, the speech or paper has not been thrown open to discussion—though even if it were, there would clearly be difficulties in the way of managers criticising their consulting engineers. Suffice it to state that

Mr. Marriott's scheme has met with almost universal condemnation from technical men who have closely analyzed it. The quarterly fathomage is not a quantity determinable with exactitude, owing to the large tonnage of ore drawn from sources apart from block-ore stope-faces. Even if it were something absolute, it would not indicate as a divisor whether the maximum profit would be obtained from the property. One mine-manager has boldly declared that the scheme will take long to understand, but will take less time to be dropped. W. Laurie Hamilton, one of our veteran mine managers, has forcibly demonstrated the fallacies of the 'new policy', and at the same time defended Rand technical control against the charges of wholesale manipulation and dishonesty implied in Mr. Marriott's pronouncements. Another vital aspect of Rand expenditures was dealt with at the Simmer Deep meeting, at which D. Christopherson discussed the influences of what may be called the Caldecott metallurgical policy. A comparison was made between the new Simmer Deep mill and the Simmer East-Knights Deep plant, started in 1903. The latter, with 80,000 tons monthly capacity, has cost about £600,000 or £215 per ton milled per working day. The former plant, of 120,000 tons capacity, will have cost £450,000, or only £107 per ton per day. The saving may be attributed to (a) heavy stamps, (b) sand-filter tables, (c) coarse crushing and high tube-mill returns, (d) large units (vats, etc.), (e) electric power. For a strict comparison the Simmer Deep should be debited with a share of the capital expenditure on the Central Electric Power Station, but the distinctions are striking enough. The 10 ft. 6 in. Sirocco fan erected in the Angelo-Driefontein mine has produced admirable results. The average air analysis before its introduction gave CO 0.011 and CO_2 0.552%, and since, CO 0.006 and CO_2 0.149. The reduction of temperature has been 2 to 3°. Artificial ventilation is being steadily extended.

DENVER, COLORADO

Dissatisfied Investors.—Clear Creek Items. — Criminal Cases. — The Coal Situation.—Cripple Creek News.

Mining in this section has been unusually quiet for this season of the year. Projects that were expected to be under way have, in many instances, been delayed for lack of funds. Whether the numerous schemes that are plainly fraudulent have made investors wary or not is yet to be determined. The case of the Penn-Wyoming Copper Co., of Encampment, Wyoming, has been widely discussed by the discontented stockholders in this company, and they have brought suit against the directors of the company. The complaint charges that E. W. Cobb, E. A. Norton, F. B. Draper, and others have defrauded the stockholders of $7,000,000 to $10,000,000, by organizing the United Smelters Railway & Copper Co., with a board of dummy directors, and transferring, without the knowledge or authority of the stockholders, the property of the Penn-Wyoming Copper Co. The United Smelters Railway & Copper Co. was to liquidate a debt of $3,600,000 against the Penn-Wyoming company. This debt in reality, the stockholders claim, was for not more than $150,000. The suit brought by the stockholders as intervenors demands a receiver for the Penn-Wyoming Copper Co. Fraud is also charged against the same men in the manipulation of the stocks and bonds of 14 other corporations most of which operate in the Encampment district of Wyoming. The Greeley stockholders of the Rio Seco Mining & Milling Co., of Oaxaca, Mexico, are just now wondering whether they were buncoed by smooth promoters, or whether nature played a trick upon them. Favorable reports were made upon the mine by engineers in Mexico. The stockholders sent an engineer to examine the property and he agreed with the previous reports. Recently Thomas Price was sent to install the new machinery and pump out the mine. He now reports to the stockholders that ore of $3.50 per ton value is all that there is in the mine. A few tons had been shipped from the dump that ran $21 per ton, and this wide discrepancy makes the investors suspicious at least.

The greater part of the mining in the Clear Creek district is now being done by lessees. Several parties are working for placer gold by drift mining in the bed of the creek. They are especially numerous below the Stanley mine at Idaho Springs. A few properties around Georgetown are being developed with the idea of shipping to the plant of the Western Metals Co., which will be operating, using the Malm process, about July 1. As soon as the Georgetown plant is in successful operation the company intends to erect similar plants in the other sulphide districts of the State. The Newhouse tunnel has been advancing steadily since April 1. The men backing the project have bought the Gunnell group, which was a famous producer in the early days, and the tunnel is being driven ahead to cut the Gunnell vein. A notable consolidation was recently effected when W. E. Renshaw, manager of the Gem Consolidated Mining & Milling Co., was appointed manager also for the Specie Payment Mining & Milling Company.

By a recent order of Attorney General Wickersham all the criminal cases against individuals and corporations holding coal lands in Colorado, which were to be contested by the Government, have been dropped. This decision comes as a result of the failure of the Government's prosecution of the Kietal case last February. This ruling, however, does not affect the status of the numerous equity

Portal of Deep Drainage Tunnel, Cripple Creek, Colorado.

cases against the same parties. The Government expects to recover title to practically all the land in dispute by these cases. The State Railroad Commission has ordered a reduction in freight rates on coal from the northern fields to Denver and Littleton. The rate gives Denver 25c. per ton reduction, and Littleton 50c. per ton. Just at this time the consumer in Denver gets very little benefit from this decision, as the northern coalfields are tied up by a suspension of work which has continued there since the first week in April. The Puritan coal mine was opened on April 26, with miners imported from West Virginia. There has been no violence thus far. The operators say they will take back their old employees if they renounce their Union. The matter now looks like a test of endurance, as the operators decline to have anything to do with the representatives of the United Mine Workers of America.

The Cripple Creek district experienced about all the changes in weather that are possible at its altitude in Colorado during April. A howling blizzard kept ore teams in for two days during the month. Then on the 12th of the month the shaft-house of the Cresson Consolidated Mining Co. was struck by lightning and burned. This helped to reduce the output for the month. The total production was 55,540 tons, with a gross value of $1,290,335. Three companies paid dividends, as follows: Portland, $60,000; Vindicator Consolidated, $45,000; and Elkton, $37,500. The deep drainage tunnel was advanced 376 ft. during April, and is now 266 ft. from the El Paso shaft. A contract has been let for a churn-drill hole from the shaft bottom to the tunnel, a distance of 400 ft. An interesting case has just been settled in court. S. Jensen shipped a car of ore over the Florence & Cripple Creek railroad to the Pueblo smelter. While celebrating, he lost his bill of lading and landed in jail. Later the Cripple Creek Mine Owners' Association presented the bill of lading and ordered the car delivered at Victor. At the trial it was decided that as Jensen had not signed the bill of lading the railroad was liable for the full value of the ore.

NEW YORK

Utah Copper and Amalgamated.—Boundary District and British Columbia Copper.—North Butte. — Heinze and his Difficulties.—Cost of Living and Rand Output.

A new element may be introduced among the low-grade milling coppers, one that will make a strong bid for the place now held by Utah Copper. The Utah Copper coterie has a present producer of immense proportions in the combined Utah-Boston, which in turn owns practically 50% in the Nevada Consolidated; they also own a controlling interest in the Ray Consolidated and the Gila, which are about to be consolidated, which combined properties have ore reserves estimated at 70,000,000 tons, and milling facilities already under course of construction; the Chino Copper Co. is also a member of the same family, and is said to be developing an immense tonnage of ore. It had the misfortune to be recommended by Thomas W. Lawson, of Boston, and as a result has been through some painful market gyrations, but as a copper property is said to be making splendid progress. The possible rival of this leadership of the Guggenheim, McNeill, Jackling, Penrose group is Amalgamated Copper. It is believed that Amalgamated has been selling Anaconda; the stock has been held strong considerably above a market parity with Amalgamated on the recent exchange basis, and, should Amalgamated see fit to do so, it could sell a minority interest in Anaconda to the public, without weakening its hold in Butte. With the cash reserve so built up it could buy into the porphyries and, with its close-working arrangement with the International S. & R. Co., make at once a large place for itself among the low-cost producers. It is not known definitely, as yet, that Amalgamated interests have taken any steps looking to the acquirement of any low-grade producers; but such a step would be logical. The present semi-demoralized condition of the copper metal market and the copper share market and the economic waste now forced upon producers, who are obliged to keep plants running and throw cheap metal upon an already glutted market, are unanswerable arguments in favor of a copper merger or some equally effective method of co-operation. If a copper merger can be brought about that will carry some lean with the fat, that will allow the high-cost coppers to live, and that will require the porphyries to limit production in return for an added profit upon such restricted output, without at the same time throttling the small independent producer, whose production must be taken care of that new properties may be developed, such a trust would be a great factor for true economy. While the copper outlook is momentarily discouraging, copper consumed is copper consumed; and there is a day ahead when cheap copper will be exhausted. Long before the point of exhaustion is reached the market will be discounting the future.

The situation in the Boundary camp is not nearly so satisfactory as it might be. One of the items of strength in the British Columbia was the holding in reserve of about one and a half million pounds of copper. During the time when the General Development Co. was trying to get control of the British Columbia and Dominion Copper, and when the metal market afforded a price of about 14c., the company refused to part with its accumulated stock. Now, it is understood, that this copper has been sold at something less than 13c. The mines have been closed for some weeks on account of labor troubles and by reason thereof the contract between the Dominion Copper Co. and the British Columbia is in abeyance. The labor situation is a very ticklish one at the moment and it may result in keeping the properties closed for some weeks to come. The Lewisohn people are now definitely understood to be wholly out of both British Columbia and Dominion. There is to be a new issue of treasury stock made by the North Butte Mining Co. Ten thousand shares will be used in the purchase of the Croesus claim, which lies between the Berlin and the Jessie ground. The authorized capital stock of the North Butte is 600,000 shares, of which 400,000 shares are now outstanding. The company has for some time owned a large interest in the Croesus and the present step is in line with the recent acquirement of the Berlin in which North Butte also owned a large share and which they have just cleaned up by taking over the whole of the title. In reference to North Butte being left out of the Butte merger, the statement is made that under the laws of Minnesota, under which the company is organized, it is necessary to have the unanimous consent of the stockholders for such a step and the management has not felt sufficiently sure of their ground to make such a request of the shareholders. F. Augustus Heinze is being kept well forward under the spot light. The shareholders in United Copper have been following the proceedings against Heinze in the Federal court closely in the hope that some of the testimony would reveal the actual condition of that mysterious company. What United Copper owns in the way of property, or stock of other concerns in its treasury, is known to none outside of Heinze and his few confidants, who themselves, are more often in the dark than otherwise. A detailed report on United Copper would be welcomed even if made as a part of the court record in a criminal proceeding. At least, one or two pertinent facts have been revealed, such as the receipt of some ten and a half million dollars from the Cole-Ryan interests at the time of the formation of the Butte Coalition, when the Heinze interests sold the Corra, the Minnie Healy and the Nipper. The disposition of this sum has never been explained. Incidentally also it has been developed that the dividends paid by United Copper were paid out of the company's capital and it now appears that such stock interests as the company held in the Davis-Daly and in Ohio Copper and Stewart Mining have disappeared from the treasury and that the only asset is the cash received from the sale of the properties mentioned, or whatever may have been received for it when it left the company's treasury. Outside of the court proceedings, where Mr. Heinze is on the defensive, he is also being forced to show his hand in the market. For some months the Heinze stocks have been in the hands of the loan crowd and during the recent depressions there have been sales under the rule, in which Ohio Copper and other Heinze issues have been under forced liquidation. The action of Ely Central, an issue which has occupied a good deal of attention and consumed a good deal of printers' ink during the past few months illustrates aptly the changed attitude of the public. A few months since, the stock was a market leader, active at several times its present price, and then had a future wholly problematical. Indications now are that the property is to justify, to some extent at least, the predictions its friends have made for it, but now the public will have none of it; in fact the market declined sharply upon the news of a recent discovery. A short time ago, a Boston commission, endeavoring to trace to its lair the high-cost-of-living microbe, obtained from John Hays Hammond an estimate of the gold production of the Rand for the coming year. Mr. Hammond's estimate of $175,000,000 seeming large, a cable was sent to the Statist of London, asking for data. Mr. Mabson, the editor, answering the cable, gives his estimate of the output for the coming year at $162,500,000, with other African properties swelling the total of gold to $180,500,000. These figures are surprisingly large and demonstrate the growth of the mining industry, there being now a much larger number of mills in operation on the Rand than at any previous time in history. Markets for mining shares are being broadened. Some of the best known of the issues on the London Stock Exchange are being admitted to trading privileges on the Paris Bourse, among them Camp Bird and Mexico Mines of El Oro. The option for examination given to the General Development Co. covering the control of the Pacific Smelting & Refining Co., the re-organization of the Douglas Copper Co., has been extended to permit of more thorough examination by the Lewisohn engineers, now on the ground at Fundicion, Sonora, Mexico. The annual meeting of the Batopilas M. Co. was held in New York last week. One of the principal matters of business was the ratification of the recent arrangement whereby a part of the property was leased to the Batopilas M. S. & R. Co., Ltd., of London. Owing to delays on account of legal details this agreement has not as yet become effective, but the new company is expected to begin operations in May.

General Mining News

ALASKA

The statement of the Alaska Treadwell Gold Mining Co. for the month ended April 15 states that the 240-stamp mill ran 30 days, 11 hours, and the 300-stamp mill ran 8 days, 19 hours, crushing 49,756 tons of ore, and producing 960 tons of concentrate. The estimated free gold amounted to $76,600 and the value of the concentrate $50,735, the total realizable value being $120,809. The operating expense was $84,110, leaving a profit of $36,696. The stock of broken ore was increased 13,857 tons.

ARIZONA

COCHISE COUNTY

Orders have been placed for new machinery for the Commonwealth property at Pearce by the lessees, and the mill which was destroyed by fire a short time ago will be rebuilt. The mill had been in operation but ten days when the fire occured. Though the machinery was not a total loss it will all have to be repaired and it will be about six months before the mill is again in operation.——The west drift on the 120-ft. level of the Whitetail property at Paradise has opened an 18-in. shoot of copper ore.——The sump on the 500-ft. level of the Holbrook shaft of the Copper Queen Consolidated Co. has been cleaned out as the raise from the 600 is expected to break through any time. At the power-plant the foundation of the old compressor has been torn out and replaced by one that will support the new one which will handle 7500 cu. ft. of free air per minute. ——The station has been finished on the 700-ft. level of the Bisbee Extension and drifts started on the ore.——At the Shattuck-Arizona the station is being cut on the 400-ft. level. It is reported that the stock of this company is to be listed on the Boston Exchange.

GILA COUNTY

(Special Correspondence).—A cross-cut driven southeast from the Williams shaft on National Mining Exploration land is 75 ft. long and has just crossed from shale into quartzite. Since cutting an 18-in. stringer of high-grade copper carbonate at a distance of 50 ft. from the shaft, this cross-cut passed for 13 ft. through faulted ground containing much iron and some copper stain.——Nathan L. Amster, president of the Arizona Commercial Copper Co., announced on leaving Globe recently that the Eureka shaft, now down to the seventh level, will be sunk 300 ft. deeper.——The connection of the third level of the Hamilton shaft with the Pinto shaft has just been completed on the Cactus property. A similar connection will be made on the fourth level within a few weeks. Much of the chalcocite recently opened averages 4% copper or better.——Preparations are being made to sink a shaft on the Wild Air claim of the Little Miami Mines Co. recently organized by James A. Fleming, former president of the Warrior Copper Co., and associates, residing in Philadelphia and New York. The new corporation is capitalized for $1,000,000, divided into 1,000,000 shares of stock, 400,000 shares of which have been assigned to the treasury. The company holds about 60 acres of mineral land, lying between the Miami and Warrior properties. Richard Fleming, of Globe, is manager.

Globe, May 7.

GRAHAM COUNTY

A new concentrating table has been added to the equipment at the Gold Belt mill in the Morenci district, and it is probable that the capacity of the mill will be doubled in the near future. L. V. Hoyt is superintendent.

MOHAVE COUNTY

E. J. McNulty, local manager for the Aztec Turquois Co., of New York, stated that his company had patented 12 claims in the Mineral Park district, and completed all arrangements for extensive diamond-drilling and cross-cutting for copper ore.——At the C. O. D. mine, on Stockton hill, under bond to McLaughlin & Boyle, a rich find was made several days ago on the 100-ft. level of the new shaft when a foot of ore was cut which assayed about $300 per ton. The new discovery was made in a drift recently started about 400 ft. west from the old workings and is believed to be an extension of the old ore-shoot which yielded nearly a million dollars in the first 200 ft. of depth. The ore just found assays about 10% zinc, $12 in gold, and nearly 600 oz. silver. The C. O. D. recently installed a fine hoist and will continue the shaft, which is now down 110 ft., several hundred feet farther.——A number of good prospects are reported in the Oatman district. In doing assessment work on the Jack Rabbit, near the Tom Reed, Billy Ridenour and John Coffey exposed a small streak of ore assaying a little over $200 per ton.——Nearby Krauss & Moore uncovered 7 ft. of good milling ore on the Lazy Boy. In the Boundary Cone shaft two shifts are averaging 2½ ft. per day. The shaft, now down 110 ft., is in good milling ore.

YAVAPAI COUNTY

The drift at the Golden Ridge Mining Co., operating in the Weaver district, is in 700 ft. on the ore, and will be advanced an additional 1000 ft. to open the Devonshire vein. ——Having spent a year investigating the resources of the district the Rigby Mining & Reduction Co. has decided to erect a lead smelter at Mayer that will have a capacity of 100 tons per day.——Work has been resumed on the Mayflower group in Government canyon three miles from Prescott. The shaft is down 80 ft. with a good showing of copper-gold ore.——The Mint Mining & Milling Co. is to erect a 10-stamp mill and concentrating plant at its property in the Copper Basin district. The shaft is now down 140 ft. with drifts on that level, and it is the intention of the manager, George Montgomery, to sink to the 230-ft. level and commence work on the vein there while the mill is being erected.——The Tom & Dick shaft of the Juanita Mining Co. is down 210 ft. and a station is being cut on the 200-ft. level.

YUMA COUNTY

The smelter of the Clara Consolidated Gold & Copper Mining Co. has been blown in. The plant consists of a 700-ton blast-furnace and a converter-plant capable of producing 45 tons of copper bullion per day. The converter building is of structural steel, and is equipped with a 50-ton traveling crane. The handling of ore from the mines to the works is all done with electric power.

CALIFORNIA

INYO COUNTY

At the Casa Diablo the mill is running on ore from the Dry Bone stope and is crushing about 30 tons per day. The management is planning to put 10-mesh screens on the batteries and re-grind the pulp to 150 mesh before cyaniding. The shaft is now down 260 ft., and will be sunk about 75 ft. per month.——At the Golden Siren group, in the White mountains, the shaft is down 90 ft. on a 4-ft. vein of milling ore. An adit has been started that will cut the vein about 1000 ft. from the shaft and a steam hoist will be installed this summer. D. C. Adamson is in charge ot the work.

MARIPOSA COUNTY

A rich vein has been opened on the surface of the Notches group, near Coulterville, and traced for 3000 ft., showing an average width of 3 ft. Frank Bixby, the owner of the property, has started a shaft.——Work has been suspended temporarily at the Hill mine but will be resumed some time this month.

NEVADA COUNTY

Work is to be resumed in the 600-ft. drift at the Belle France group of claims in the Grass Valley district.——The drift at the Oakman mine, in the Washington district, has opened 6 ft. of $15 ore.——The Ethel mine above Gaston has resumed operations after having been idle all winter. At the time work was stopped on account of the bad weather the drift had opened a promising shoot and it is on this that the work will be concentrated.——A new compressor has been installed at the Norton group, in Willow valley, by the new owners and extensive development is planned. J. M. Fly is manager.——The last clean-up at the Champion resulted in a bar valued at over $4000 which will be more

than enough to satisfy the claims of the men.——New machinery is to be installed at the Kenosha mine and operations resumed on a larger scale.——The Roseville Mining, Milling & Leasing Co., which recently secured an option on the West Delhi group of claims on Columbia mountain, has commenced work in the 400-ft. adit and will drive it ahead about 175 ft. to intersect the vein. This will give the company about 700 ft. of backs.

PLACER COUNTY

The recent cutting of the channel in the Red Sea mine, three miles from Forest, has proved quite a stimulation to the mining of that district as the gravel has proved to be of considerable extent and of good value.——The Good Friday Gold Mining Co., which controls the Good Friday, Green, Enterprise, and Hilltop groups about three miles from Auburn, has commenced active work on the properties. The Good Friday is one of the pioneer producers of the county having yielded about $250,000 in the seventies.——Development is progressing steadily at the Crater and the mill is kept running night and day.——J. Toman has secured a lease on the Hibbe copper mine near Gorden bar on Bear river and will commence work in the shaft which has been sunk to a depth of 110 ft.——The adit at the Dewey is in over 400 ft. and has but a short distance to go before it will be under the shaft when a raise will be started.

SAN BERNARDINO COUNTY

(Special Correspondence).—The Gold Stone district north of Barstow is attracting considerable attention. A series of important discoveries have been recently made and work is under way on a dozen promising claims. Water is scarce and it is probable that two wells will be sunk in the hope of increasing the supply, which is now derived from Indian Springs and a few wells.——Smith & Parke are sacking ore on the First Chance claim for shipment to the Victorville mill. It assays $50 to $60 per ton.——The sinking of an incline shaft will start immediately at the Drumm-Barlow mine, 30 miles north of Barstow. The return on a recent shipment of ore to the Needles smelter was $97 per ton gold and 5 oz. silver. This was taken from surface workings.——The railroad has reduced the rates on ore shipments from Barstow to the Victorville mill as follows: $50 ore, $3; $20 ore, $2; $15 ore, $1.50 per ton. The mill is running steadily.——N. K. Millet is erecting a small mill near Dagget to treat ore from the Calico and nearby properties.—A miners' club has been organized at Barstow to exploit the resources of the district.

San Bernardino, May 9.

SHASTA COUNTY

E. F. Jones, a miner at Keswick, opened a pocket in one of the streets of the town and took out $385 in gold nuggets.——The Bank of Tehama County shipped a gold bar valued at $25,000 which represented the output of the Midas mine, at Harrison Gulch, for April. The shipments have been averaging about $30,000 per month.——The recent threatened strike at Coram has been avoided as the officials of the Western Federation of Miners have refused to sanction the action of the smeltermen who quit because a non-union man was promoted over them.

SIERRA COUNTY

(Special Correspondence).—The Middle Yuba Hydro-Electric Co. expects to have its power lines completed to Alleghany within a few weeks.——The owners of the Haskell Peak have decided to resume operations at once. Henry Goering is manager.——The Rainbow Extension Co., near Alleghany, has decided to erect a mill this summer. The adit is in 300 ft. and is being driven on the vein in which the ore-shoot is three feet wide and of milling value throughout its developed length. O. A. Harlan is manager.——The Phoenix mine, near Sierra City, has been bonded to James Buckley and J. S. Daveler, of Alameda. It is equipped with a 10-stamp mill.——The Swastika company has placed orders for a 10-stamp mill which will raise the total of the company to 20 stamps. Lawrence H. Holly is superintendent.——George S. Stone and associates have purchased a hoist for the North Fork mine and expect to place eight men at work before the end of the month.——The Gray Eagle mine has been attached for supplies furnished by grocery firms.

Alleghany, May 9.

TRINITY COUNTY

(Special Correspondence).—The Keating property on the north fork of Trinity river will have a 5-stamp mill erected this summer. There are four claims in the group and a number of small rich veins have been opened.——Neely Thomas, operating on the flats at the head of Coffee creek, is to build a mill this summer.——A two-drill Rand compressor plant is being installed at the Wagner property on Coffee creek. It will be driven by water-power.——The Blue Jay will begin the installation of an 8-hp. Graupner mill this month as arrangements have been made with the owners of the water in Morrison gulch to supply water for power. A large sulphide vein has been opened by the main adit.——The capacity of the Headlight sawmill will soon be doubled. Elias Ellery has secured the logging contract.

Carrville, May 9.

TUOLUMNE COUNTY

(Special Correspondence).—The company which recently acquired the Moffitt gravel mine on the Tuolumne river near Jacksonville is expending a large sum of money in preliminary work and equipment.——The work of repairing the collar of the Providence shaft is progressing satisfactorily and additional men will soon be put to work. The mill at the Dutch mine will be started within a few days. The extension of the drift on the 400-ft. level into the Sweeney mine, which adjoins the former and which is under the same management, is contemplated. The two properties have been connected on the surface by a car-track.——Milling has been commenced at the Yellow Rock mine, and it is the intention to install a cyanide plant.——High-grade ore has been uncovered on the 100-ft. level of the Ida Klein mine, near Stent.——A new hoist is being installed at the Sunnyside mine, south of Tuolumne.——The new adit being driven at the Leap Year mine, on Table mountain, has entered a strata of rich gravel.

Tuolumne, May 9.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—A. H. Colburn, manager for the Reliance G. M. Corporation, states that a plant of machinery will be purchased at once and installed at the Sport-

Old Town Mine.

ing Times property in the Georgetown district.——The Homestake G. M. & M. Co., operating a group of claims on Lincoln mountain, is to purchase a small compressor-plant during the next 30 days. A. L. Stephens is manager.——W. E. Renshaw, principal owner of the Gem mine, has been appointed general manager for the Specie Payment Mining & Milling Co., succeeding A. M. Wells.——The King Solomon property at Lamartine, will be entered among the list of steady shippers during the month.——The mill at the Katie Emmett mine is to be enlarged, five new rapid-drop stamps having been purchased. Ford & Cannady are operating under lease.——The Tolland adit, owned and operated by Albert Hall, has intersected the Lamartine vein to the west and a fine streak of ore has been uncovered.

Idaho Springs, May 7.

GILPIN COUNTY

(Special Correspondence).—The Pozo property in the Nevada district has been entered among the list of shippers. Ore is being sent to the custom mills for treatment.——It is believed that inside of two weeks the Eureka mill will be ready to start. J. N. Caldwell, of Denver, is manager. ——Two carloads of ore were shipped last week by Shearer & Co., operating a lease on the Old Town, to the Modern smelter at Utah Junction.——The Benzie Investment Co. has secured a bond and lease on the Victor property.

Central City, May 7.

GUNNISON COUNTY.

The cutting of a number of rich silver-lead veins of ore in the Dupont tunnel which is penetrating Galena and Treasury mountains has definitely decided the building of an immense water-power and milling-plant by this company. The starting of this new enterprise will be no later than June, and will, in all probability result in operations commencing on many other promising properties in that section.——The Hard Cash Mines Co., whose properties lie at the north side of Galena mountain, has decided upon putting in a compressor-plant and a pyritic smelter by which the ore will be smelted to 60% copper matte. Gasoline will be used to drive the compressor engines and crude petroleum to smelt the ores.——It is understood that the North Pole property will renew work in Crystal Basin this season and a matte furnace will be built later somewhere down near the river to which the ore will be delivered by a tramway from the mine.——O. F. Thomas is planning to start up his mine above Gothic in a few days.

LAKE COUNTY

Work has been started on the Helena shaft in Iowa gulch and wires are being strung to bring power from the mains of the Leadville Light & Power Co. A new electric hoist, two compressors, and pumps are to be installed.——A new company has been formed to re-open the old First National claim in the same district.——Connections with the Silent Friend have been through the Yak tunnel and in the future the property will be operated that way.——The Penn property, on Breece hill, continues to be one of the steadiest producers in the district. A number of lessees are working in the mine and meeting with good success.——A stringer of high-grade ore has been opened in the winze sunk in the St. Louis adit and drifts started to explore it.——Ore is now being hoisted from both shafts of the Baby property in California gulch.

TELLER COUNTY

The measurements taken at the Roosevelt deep drainage tunnel show a gain for the month of April of 376 ft. The total length of the tunnel is now 13,218 ft., the distance remaining to the main water course will not exceed 2500 ft. ——The plant at the main shaft of the old Rittenhouse company's Gold hill property, now owned by the Cripple Creek & Colorado Gold Mining Co. has been started by Carlson and others, who have taken a two years' lease on the 11 acres contained in the Happy Year, White Elephant, and Fraction No. 1 lode mining claims. The shaft on the Rittenhouse has been sunk to a depth of 900 ft. and the present lessees will prospect the ground by extending the several drifts and cross-cuts.——The Anaconda mill has been overhauled and additional machinery of improved design installed preparatory to its active operation. The mill has a capacity of between 40 and 50 tons per day, and negotiations are under way looking to the entering into a contract for the treatment of all ores mined on the property of the Mary McKinney Mining Co. by O. Keener and associates, who have made an important surface discovery of milling grade ore. The mill is under lease to Pascal Craig, under whose personal supervision the alterations to the plant have been made.——The Callie Leasing Co., operating the Callie mine of the Stratton estate, a Gold hill property adjoining the Lucky Corner, has resumed shipments.

WHITE PINE COUNTY

The United Mining & Holding Co. has purchased the Spar copper group of claims from the estate of C. L. Tutt. The group contains 55 acres of patented ground and has been opened by 2200 ft. of development work disclosing a series of veins.

IDAHO

ADA COUNTY

The George F. Root Mining Co. is building a 50-ton mill at Boise and contracts have been let for stamps, concentration tables, and tanks for a cyanide annex. The concentrate will be re-ground and cyanided. F. M. Field is the metallurgical engineer.

BINGHAM COUNTY

(Special Correspondence).—The Inter-Mountain Placer Mining Co., managed by Fred W. Crockett, has installed and put in operation a cyanide plant on the Snake river, four miles from Blackfoot, for treating the auriferous sand on the banks and benches of the stream. The material consists of ordinary sand and magnetite, containing fine gold in free particles and as a film on the black sand. It is said to contain 50c. per ton. The stuff is moved by scrapers and passed dry through a revolving trommel, giving an undersize product of 20-mesh and reducing 4½ tons to 1 ton. It is elevated to a launder and sluiced to leaching tanks in which 0.21 lb. KCN is used per ton of screened product. Thomas Ferguson, of the Holden Cyanide Process Co., of Salt Lake, who installed the plant, states that the screened material will average $2 per ton, and that it can be screened and cyanided at a cost of 75c. per ton, the extraction reaching 90% and over.

Blackfoot, May 6.

IDAHO COUNTY

The American Eagle mine, eight miles east of Elk City, has been bonded to A. W. Boyd and will be re-opened. The property has been idle for several years but paid well when operated previously under the supervision of Mr. Boyd, and is expected to become an active producer in a short time as the property contains several good shoots and is equipped with a 10-stamp mill.——It is reported that the Butte-Oregrande mine has been sold.——A rich discovery has been made on the Topeka claims where telluride ore assaying high in gold and silver has been found.

SHOSHONE COUNTY

Statements filed with the assessor of Shoshone county show that the net profits of the mines in the Coeur d'Alene district were more than $2,100,000 in 1909, five of the prominent companies reporting as follows: Federal Mining & Smelting Co., Mace mine, $469,155; Wardner mines, $350,678; Bunker Hill & Sullivan, $575,547; Hercules, $325,305; Hecla, $189,169; Snowstorm, $169,966. The Morning mine at Mullan was the only big producer worked at a loss last year, the net amount of expenditures over receipts being given as $58,822. The Hercules and Bunker Hill & Sullivan also spent large amounts in improvements and repairs.

MISSOURI

JASPER COUNTY

(Special Correspondence).—It is the plan of a number of the large mining companies owning mining lands to reduce the royalties for the lessees, to encourage prospecting, and development of the properties.——One of the main developments going on in the district at present is the prospecting by the Granby company.——The Carl Junction camp is coming into greater importance through the efforts of three companies in different parts of the camp. To the north J. B. Meredith has taken a lease, installed a centrifugal pump, and drained the land to the upper levels. To the south the Mohler-Smith Co. has installed two additional pumps and is keeping the water down. This company has also built dikes around the mouths of the old shafts and drifts in order to keep the water from overflowing from the high-water season of Center creek and Spring river. A Kansas City company is draining old shaft No. 1 and a centrifugal pump recently installed has proved very satisfactory.—— In the Alba-Neck City camp there is greater activity than at any time in the past three years. Several old properties have been taken over by new operators and are now producing.——The Cliffwood company has been extending its holdings by taking over the leases of the Sand Hill and the Van Hoose properties in the same vicinity.

Joplin, May 7.

MONTANA

BROADWATER COUNTY

The Radersburg Consolidated Mining Co., which recently took over the Ohio-Keating gold property, is likely soon to come into possession of two other properties; one of the Dewdrop group of claims adjoining the Ohio on the northeast, and the other a group of three claims lying about 1000 ft. south of the Black Friday property. It is said that the Black Friday property has opened a body of ore at a depth of 450 ft., where the vein is said to be widening. Some of the ore taken out recently averaged about $50 net per ton. Good progress is being made in installing the electrical equipment at the Keating Gold Mining property, and provided no delays occur the surface plant on the Blacker claims will be in operation this month.

LINCOLN COUNTY

The work of installing the machinery in the new mill at the Sylvanite mines is now in progress by the Lincoln Gold Mining Co., and it is thought that the mill will be in operation within a month. The mines are being retimbered and miners will soon begin taking out ore.

NEVADA

ESMERALDA COUNTY

On May 7 the Ford-McKay lease on the southern end of the St. Ives claim of the Merger Mines Co., at Goldfield, opened one of the richest shoots in the district. The drift on the 250-ft. level had been following a 2-ft. vein from which ore assaying about $100 per ton was being sacked when the rich shoot assaying over $1000 for a width of 3 in. was opened.——At the Goldfield Annex lease a raise is now being driven from the north drift 80 ft. north of the shaft to tap the ore-shoot at that point and explore the fault zone nearer the shaft with a view to sinking to tap the extension of the big vein. The ore opened on the intermediate level above the 800 has proved somewhat erratic and pockety.——The buildings for the mill and accommodation of the men at the Del Monte property at Mina have been completed and the machinery is being placed in the mill. The ore-bins at the mine have been filled though it is probable that more bins will be erected at the mill as it is the intention of the company to accept custom ore.

HUMBOLDT COUNTY.

There has been considerable activity in the Seven Troughs district lately and there has been some talk of consolidating the claims in that camp with the Coalition group as a centre.

LINCOLN COUNTY

(Special Correspondence).—The Pioche Metals Co., which installed a gasoline hoist about the first of the year, has since then sunk a shaft 290 ft., and the intention is to continue sinking till a depth of 400 to 500 ft. is reached. When the bottom of the shaft is at the 300-ft. level a crosscut is to be run to the ore, which occurs in a contact vein between limestone and shale. It has been decided to install an air-compressor, to be driven by a gasoline engine. A carload of ore on the dump, soon to be shipped, is believed will net $20 per ton, after shipping and smelting charges are paid. The ore contains principally silver and lead. The company owns seven claims, and has under bond at $60,000, the 12 claims of the Pioche Consolidated Mining Co., all situated four miles from Pioche. David Lemmon is in charge of the work, C. A. Cook, of Salt Lake, being secretary and treasurer of the company.

Pioche, May 7.

NYE COUNTY

The main shaft at the Belmont mine, at Tonopah, cut an orebody 60 ft. below the 1000-ft. level that has the appearance of becomming a bonanza, the whole bottom of the shaft being in good milling ore.——As the result of the semi-monthly clean-up of the Montana Tonapah for the last half of April, 25 bars weighing 80 lb. each have been shipped to the Selby refinery bringing the total bullion shipment for the month up to 4100 lb. In addition to this 101 tons of concentrate were forwarded to the same firm. The mill is reported to be making an extraction of 91.6%.——At the Tonopah Extention mill the clean-up resulted in 17 tons of sand concentrate valued at $550 per ton, 18 tons of slime concentrate valued between $250 and $300 per ton and 8 bars of bullion weighing 900 lb. and valued at $9000. The mill is treating 110 tons per day and underground good ore is being opened by the development work in all parts of the mine. This is especially true on the 400-ft. level where the stopes have opened several good orebodies.——The Round Mountain Mining Co., at Round Mountain, shipped $33,000 worth of bullion as the result of the April clean-up.

WHITE PINE COUNTY

(Special Correspondence).—The Giroux shaft has been permanently timbered to the 1000-ft. level and the surface is being graded for a new hoist. Two compartments have been sunk to the 1200-ft. point, the remaining three will be completed at an early date.——The April output of the Nevada Consolidated was approximately 6,000,000 lb. of blister copper. It is understood that no effort will be made to increase production at this time and that the installation of a steam shovel on Liberty ground and the addition of a new unit to the concentrator will be postponed until next fall.——The Amalgamated Nevada Mines Co., operating a group of gold properties at Blackhorse, is installing a 10-stamp mill, two concentrators, and an electric lighting plant. James H. Marriott is general manager.

Ely, May 7.

NEW MEXICO

SIERRA COUNTY.

(Special Correspondence).—The Black Range Reduction Co. is having surveys made near the hot springs in the vicinity of Monticello preliminary to the installation of electric machinery for producing about 200 hp. for the company's properties in the north end of the district.——The owners of the Gold Dollar properties expect to install a large plant of machinery including air-compressor and other surface equipment soon.——A telephone line has been completed a distance of about three miles from the office of the U. S. Treasury Co. at Chloride to this company's main workings at shaft No. 1.

Map of New Mexico.

Chloride, May 7.

SOCORRO COUNTY

(Special Correspondence).—The drift on the 300-ft. level west of the Ernestine Mining Co. is in good ore the vein being approximately 5 ft. wide. The mill crushed 680 tons during the week producing 53 sacks of concentrate though no bullion was smelted.——In the Deadwood mines crosscuts on the No. 4 level are being driven through the No. 2 orebody.——The new mill of the Socorro company is run-

ning smoothly now crushing about 100 tons per day. The capacity of the Burt filters has been doubled to handle the whole amount of pulp from the stamps.——The lower levels of the Mogollon Gold & Copper Co. are being kept free from water, and development is being carried forward from the main adit.

Mogollon, May 6.

OREGON

BAKER COUNTY

The Mollie Gibson Gold Mining & Milling Co. has been incorporated to open the Mollie Gibson group of claims on the north fork of John Day river a few miles from Bourne. There is a 4-ft. vein on the group which is composed of 12 claims.——The management of the Gold Bug mine in the Susanville district has purchased the hoist that was installed at the Mountain Belle property and is now erecting it on the 300-ft. level of the Gold Bug. It is reported that the company will commence shipping the high-grade ore some time in June.

UTAH

The 44 members of the senior class of the Colorado School of Mines are in Utah for a week of instruction and observation at the various mines and metallurgical plants in the State. The party is accompanied by the following members of the faculty of that school: A. J. Hoskin, A. C. Smith, mining; F. W. Traphagen, W. G. Holdane, metallurgy; H. B. Patton, geology; F. H. Cronin, mechanics. Butte and Anaconda are to be visited next.

JUAB COUNTY

(Special Correspondence).—The Uncle Sam mine, which is under the superintendency of C. C. Griggs, of Knightsville, is shipping about 30 tons per day of ore running $30 per ton, and the prospect is that this rate of shipment will be kept up during the year. The May Day, under the same management, is milling a small tonnage of ore and shipping some first-grade, the return from concentrate and crude ore being sufficient to pay operating expenses. In prospecting on the May Day to a depth of 1100 ft. the lowest workings were still in the leached zone, and heavier equipment will probably be provided for further sinking. ——A new Hendrie & Bolthoff double-drum electric hoist will soon be installed at the 900-ft. shaft of the Yankee Consolidated Co. near Eureka, which will afford facilities for deeper sinking. The first 300 ft. was in porphyry, below which was limestone. Cross-cuts from the shaft have opened leached out veins at the 400, 500, and 800-ft. levels, and the object of further sinking is to open these veins where their filling may be mineralized. The old workings, from which five or six cars of ore were mined and shipped in April, are entered through a 2000-ft. adit, a 500-ft. incline from which was sunk 200 ft. in ore. This ore was found in parallel channels. The ore shipped was of two grades; the first-grade assayed 35% lead and 30 oz. silver; the second, 18% lead and 15 oz. silver per ton. L. Merriman, the superintendent, states that the dump contains 18,000 tons of milling ore.

Eureka, May 5.

WASHINGTON

OKANOGAN COUNTY

The Detroit-Oroville Exploration Co. has commenced drilling its property with a Sullivan Beauty machine that has a capacity of 800 ft. A 30-hp. boiler has been installed and three holes totaling 1000 ft. will be put down to test the ore.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—The recent discovery on the Athabasca mine near Nelson is showing up well. The gold-bearing vein is 10 to 18 in. wide and has every appearance of continuity as far as opened. The ore contains a small percentage of silver, but the gold mills freely.——The ore now being opened up on the Panama on Sheep creek assays as high as 2220 oz. silver per ton.——The Aurora Mining & Milling Co., at Moyie, has taken a lease on the Alice concentrator at Creston and will separate the zinc from its silver-lead ore at this works before shipping to the Trail smelter, where zinc-bearing ore is penalized. The zinc concentrate will be shipped to the Empire Zinc Co. at Denver. ——The amount paid the lead miners of this district on account of bounty during the year ended March 31 was $335,000, about the same amount as for the previous year. It amounted to about 75c. per 100 lb. of lead. All of the ore was treated at the Trail smelter.——The strike of miners at Greenwood has not resulted in an absolute shut-down of the B. C. Copper Co. workings. The management has announced its intention of continuing to work and has a force of 25 men at the mine and 35 at the smelter. The B. C. Copper Co. has finally secured a contract from the Dominion Copper Co. whereby the latter is to begin shipments of ore to the Greenwood smelter.——The Nicola Valley Coal Co. will build 1000 coke ovens as soon as the construction of the Kettle Valley railway is under way. The Pacific Coast Collieries property at Merritt will be opened shortly with a force of about 150 men, producing 500 tons per day. A 17-ft. vein has been found on the 107-ft. level. The Diamond Vale property in the same district is soon to put a force of 100 men to work. There is a probability of the Coal Hill syndicate starting work on its property.—— The Canadian Pacific railway mining department has secured control of the coal properties of the Western Fuel Co. as an offset to the acquisition of the Dunsmuir mines by the Canadian Northern.——Large coal deposits have been found 200 miles north of Hazelton. It is of a bituminous character. One seam opened up has proved over 12 ft. thick.

Rossland, May 7.

In the Coast district there is much activity in coal mining; also much speculation in connection with prospecting in the Portland Canal district, where some ores returning high assay value in gold and silver have been found. Two or three companies are developing their mineral claims in a way that will prove their mining possibilities, but there are some of which this can not at present be said. The Portland Canal Mining & Development Co., in particular, has gone about its work in a systematic manner, first opening its property by several prospecting adits, and afterward erecting an aerial rope-way for conveying supplies to the claims and ores to a small concentrating mill it is equipping near the railway line. Among those reported to be largely interesting themselves in the new mining camp are Mackenzie & Mann, the well known firm of railway men, of Toronto, Ontario, who are stated to intend mining and smelting on a considerable scale in the district, besides building a railway of 20 to 30 miles to tidewater.

MEXICO

CHIHUAHUA

In a circular to the stockholders of the Rio Plata Mining Co. Henry W. Miller, the president, states that on completion of car No. 38 of concentrate, March 5, the stamp-mill was closed down in conformity with the recommendation of the general manager in the last anual report, in order to utilize the whole of the cyanide plant in reducing the accumulation of tailing to a point where all danger of loss during the rainy season will be eliminated. The stamps will again be put in operation about July 1 when the rainy season sets in. The general manager estimates that the minimum average net monthly profit for the fiscal year 1910 will be $20,000. The present quarterly dividend of 2% will be maintained until the board of directors think it advisable to increase it. The total value of the silver recovered during the month of March was $26,711 and the net operating profit $17,371.

SONORA

J. S. Williams, Jr., the superintendent for the Moctezuma Copper Co., is authority for the statement that the company will install an aerial tramway from the concentrator to Nocazari canyon to dispose of the tailing from the big plant. There has been a great scarcity of water this year and the tailing has not been washed away by the river as was expected.——A. J. King and associates have secured a bond on the Cinco de Mayo property south of Douglas and will develop the property on a larger scale.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

RALPH ARNOLD is at Washington.

ERROL MACBOYLE has gone to Nevada.

W. W. ORCUTT has gone to Washington.

E. J. SWEETLAND is at Guanajuato, Mexico.

SEELEY W. MUDD is expected at San Francisco.

COURTENAY DE KALB has returned to San Francisco.

H. F. A. RIEBLING, of Denver, is in Illinois examining lead mines.

BASIL PRESCOTT, who recently returned from San Salvador, was in San Francisco.

FRANCIS A. THOMPSON was at Republic, Washington, recently on professional work.

GARDNER F. WILLIAMS will attend the Semi-Centennial of the University of California.

L. HIGGINS was in San Francisco this week returning from Nevada to Los Angeles.

J. S. MCARTHUR was in San Francisco May 7 on his way from Cobalt, Ontario, to Mexico.

C. R. VAN HISE will attend the International Geological Congress at Stockholm this summer.

ROBERT MUSGRAVE is with the Exploration Company of England and Mexico, in Mexico City.

CLIFTON H. WILDMAN is manager at the Morning and Evening Star mines, Ward, Colorado.

H. VINCENT WALLACE is at the mines of the Tularosa Copper Co., Bent, New Mexico, this month.

ELMER A. HOLBROOK has returned to the East from Mexico, but is leaving immediately for a trip to Cobalt.

JOHN M. NICHOL is representing the Hammond Iron Works and the Hendryx Cyanide Co. at Mexico City.

MAURICE W. SUMMERHAYES, of El Paso, has gone to New York, Toronto, and Montreal on his way to London.

LUDWIG ROSE, mining assessor, of Cologne, Prussia, has been in Utah recently investigating mining and machinery methods.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the months January to March, 1910:

	Tons.
Exports of copper	44,663
Imports of copper	1,705
Consumption of copper	42,958

as compared with consumption during the same period in 1909 of 34,029 tons. Of this quantity 40,022 tons were imported from the United States.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

W. F. C., Rosario, Mexico: Common yellowish green epidote.

H. A. C., Ingot, California: Quartz-vein rock stained with limonite and containing galena. No tungsten.

F. G. C., Lordsburg, New Mexico: The clay appears to be a disintegrated volcanic rock. It is not a fire-clay on account of its easy fusibility.

J. C. S., Danville, Washington: No. 1, a contact phase of granite or diorite; No. 2, quartz-vein rock stained with limonite; No. 3, diorite; No. 4, granite porphyry; No. 5, biotite diorite; No. 6, contact phase of granite or diorite; No. 7, diorite; No. 8, feldspar pegmatite.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING CLAIMS—ADVERSE POSSESSION

A possessor's right to ground covered by a mining claim, regardless of whether or not it was subject to location as a mining claim, may be supported by adverse possession alone. And such possession would give him all ledges or veins apexing within the boundaries of the claim, and the right to follow them within his side lines extended vertically downward. Whether or not such adverse possession would carry with it extralateral rights, in the event the ground passed to a town-site for town-site purposes under a patent seems never to have been passed upon and settled, and the Supreme Court of Nevada declined to pass upon the question, where the validity of a location could be determined without passing upon that particular question. But if the claim in question never passed under a town-site patent, then the locator is entitled to any extralateral rights which he may have established by the evidence. And the rule is that a valid and subsisting mining claim on land covered by a town-site patent at the time the patent was issued does not pass thereunder, nor is the title or right of possession affected thereby under the United States statute declaring that no title shall be acquired to any mine of gold, silver, cinnabar, or copper, or to any valid mining claim or possession held under existing laws.

Golden *v.* Murphy, (Nev.) 103 Pac. 394, July '09.

TOWN-SITE PATENT—EFFECT ON MINING CLAIM

The Supreme Court of Nevada questioned whether a discovery, sufficient to support a valid mining location so as to exempt such location from the provisions of a town-site patent, could be held to the same degree of strictness as would be required in the case of a mine known, or claimed to be known to exist at the time of the issuance of such town-site patent, but which had not previously been located. And where it appeared that the ground embraced within what was popularly known as the Canyon claim was sold as town lots under a town-site patent, it did not appear that the lot purchasers ever acquired a possession from the claimant to the ground under prior existing mining locations. It appeared, too, that the ground covered by the Canyon claim had been held as a valid and subsisting mining claim from a time long prior to the date of the town-site patent, continuing to the date of the controversy, and that no one ever questioned the right of the present claimant and prior locators of the ground covered by such Canyon claim to hold the same as mining ground and has never attempted to establish a superior right to said ground. Accordingly the Canyon mining claim was said to be a valid mining claim unaffected by the town-site patent.

Golden *v.* Murphy, (Nev.) 103 Pac. 394, July '09.

BOUNDARIES OF MINING CLAIM—MEANING OF 'ABOUT'

In describing the boundaries of a mining claim and in giving distances of the lines by the use of the word 'about' in connection with a certain given distance is meant that the given distance is not to be taken with exact precision, but that established corners and monuments are intended to control the actual distance stated. And in case of doubt as to boundary lines, monuments and lines actually marked and capable of identification control courses and distances.

Bullion-Beck & Champion Min. Co. *v.* Eureka Hill Min. Co., (Utah) 103 Pac. 881, Aug. '09.

PARTNERSHIP IN WORKING MINE

Persons who own a mine as tenants in common may form a partnership to work it in which the mine itself may or may not become a firm asset; or such persons may agree to work the mine in common without a partnership. But where a partnership was formed between tenants in common to operate a mine constituting the common property and after the mine had been so worked, one of the partners was entitled to sue his co-partners in equity for an accounting.

Howard *v.* Luse, 171 Fed. 584, June '09.

MINING LEASE—RECOVERY OF MINIMUM RENTAL

A lease of a coal mine provided that the lessee should not be required to pay the minimum rental but might continue mining operations where the coal was less than 2½ ft. in general thickness. In an action by the lessor for the minimum rental, the Supreme Court of Pennsylvania said that the burden was on the lessee to prove that the coal was of less thickness than 2½ ft., and where the evidence was conflicting, and tended to show that the lessee had not made proper examination to test the actual thickness, the lessor was permitted to recover.

Holt *v.* Kelley, (Pa.) 73 Atl. 947, May '09.

VALIDITY OF MINING CLAIM

A valid mining claim can only be based upon a discovery within the limits of the claim, and the existence of mineral in such quantities as to render the land more valuable for mining than for any other purpose, and the mineral discovered should be such and in sufficient quantities as to justify a prudent man in the expenditure of time and money in the exploration and development of the claim.

Golden *v.* Murphy, (Nev.) 103 Pac. 394, July '09.

COMPANY REPORTS

BROKEN HILL PROPRIETARY, LTD.

The forty-ninth semi-annual report of this company states that owing to labor troubles in Australia work underground with the exception of keeping the mines drained has been entirely suspended. As many of the mines at Broken Hill were short of coal and supplies, this company sold a portion of its stock, but had to curtail these sales owing to the long continuance of the strike. At Broken Hill the concentrator was kept running till near the end of the year, when it was shut down to give the Port Pirie smelter the benefit of the supplies on hand and keep it in continuous action, as it was here that the company was treating contract ore. The mill treated 184,387 tons of tailing from the dumps, producing 23,354 tons of slime, 8363 tons of lead concentrate, and 151,859 tons of re-ground tailing for further treatment in the zinc plant. The re-ground tailing produced 40,055 tons of zinc concentrate. The smelter treated 106,338 tons of material producing 39,826 tons of lead, 1,920,824 oz. silver, and 944 oz. gold. A new bag-house has been erected by the company and 3196 tons of sulphuric acid made. Of this 985 tons have been sold at satisfactory prices, the rest being used in the company's refinery. The average price for lead per ton was £12 17s. 11d., and for silver per ounce, 2s. 1½d.

STANDARD CONSOLIDATED MINING CO.

The year for this company, operating at Bodie, California, has been rather unsatisfactory, as work carried on during the past thirty-one years has almost exhausted the ore-supply. Old drifts and stopes were re-opened at heavy cost to secure low-grade ore that had been left in early days, and poor ore taken from the dumps. In the mill 20 stamps were kept in operation 168 days. During the year 10,990 dry tons averaging $14.16 were mined, milled, and treated in the slime plant at a total cost of $13.15 per ton, with an extraction of 86.76% for the entire plant. The New Standard mine purchased in 1907 has been prospected but no amount of milling ore opened. During the year the company has bought the Golden Lily claim, which is well situated and expected to contain bodies of commercial ore.

NIPISSING MINES COMPANY

The fifth annual report of this company, operating mines at Cobalt, Ontario, states that dividends amounting to $1,500,000 have been paid during the year and ore reserves estimated to the value of $3,269,000 blocked. There was mined 6412 tons ore containing 4,646,876 oz. of silver, the metal being recovered at a total cost of $0.1639 per ounce. Trenches aggregating 33.1 miles were dug to a depth of 3.4 ft., and 8451 ft. of development work underground carried forward.

Keeping Shop Records of Belting

The average mill and smelter buys a large amount of belting each year, which is chopped up and put on various machines throughout its plant as belting gives out. Few plants keep any record of the actual length of service of the belts. At the end of a year's time it is not definitely known whether the belt equipment for the various kinds of machinery in the shop has cost more than it should. All users of belting will be interested in a plan of keeping shop records which has just been devised by the engineers of the New York Leather Belting Co, 51 Beekman street, New York City. Charts have been printed which can be tacked up on every floor in a factory, and, by merely filling in certain blanks, entailing little or no trouble, at the end of the year the exact record of belts on every machine on that floor can be absolutely checked up. The charts may be had by applying to the above company.

New Placer Mining Machine

The solution of the economical use of water, which has baffled placer miners for a long time, is said to have been satisfactorily worked out in a machine which is this month being placed on the market for the first time by The Moran Company of Seattle, Washington. The patent rights of the new apparatus, which is a gold-saver and tailing stacker combined, have been taken over from the Sibbett Mine Equipment Co. of Seattle. Associated with this company are J. B. Hodgdon, a mining man of long experience, and George E. Sibbett, a conveying engineer of known reputation. It is claimed that the machine, which has been named the Hodgdon, reduces the amount of water required for hydraulic mining to one-fourth the volume heretofore employed, or virtually increases the efficiency of the miner's inch about 400%. The machine rests on rails and can always be kept close up to the working face of the mine, with the result that the gravel capacity of each giant is practically doubled. In mining, the gravel is piped into the conveying flume, in the same manner as in bedrock flumes, but the water used in breaking down the face is all that is required to concentrate the gold, and this may be used over and over. The gravel is advanced by conveying machinery instead of the force of water, and a higher percentage of gold extracted than can be obtained by the ordinary sluicing methods. The flume is elevated at an angle of about 30°, and the tailing easily disposed of by being carried to any desired height. This machine uses only about one-fifth the power of a dredge of the same capacity. The manufacturers confidently expect that through the use of the Hodgdon system, hundreds of acres of placer ground will be opened up that were heretofore considered of too low grade for profitable mining.

Cost of Power Transmission—Electricity Versus Compressed Air

The Pneumelectric Machine Co. of Syracuse, New York, was recently asked to submit figures based upon the following assumptions; distance of transmissiou, 1 mile; power delivery to the mining machines, 200 hp.; air-pressure delivery, 80 lb.; voltage delivery for direct-current motor, 250; allowable loss of pressure in transmission, 10%; allowable drop in voltage in transmission, 10%. Assuming 20 cu. ft. of free air per minute required per brake horsepower for the air machine, the calculation shows that 620 cu. ft. of compressed air at 80 lb. would be delivered per minute, and that by D'Arcy's formula this volume would require an 8-in. transmission pipe. At $1.78 per foot the pipe one mile long would cost $8400. This then is the cost of the installation of the piping. In the case of the electric transmission, by assuming 93% efficiency for the motor, and at current prices for copper and cable hangers, calculation shows that the 640 amp. required at the motor would necessitates a cable of 1,250,000 cm., which would weigh 79,800 lb. The cable would cost $11,970 and the hangers $510, making a total cost for electrical transmission of $12,480. These figures show that as far as the cost of installation goes the air transmission would be cheaper than the electric wires, but the installation cost is really a small part of what might be termed the expense of transmission. The choice of system is reversed when the total expense is considered. This is shown by the size of the power station. For electric transmission 640 amp. at 278 volts would mean that the generator would supply 178 kw., and assuming a combined efficiency of engine and generator of 86%, 207 kw. or 278 hp. would be required at the power-house to produce 200 hp. at the motors. At $30 per horse-power, the annual expense would then be $9400. With the air transmission, on the other hand, a 2-stage compressor would require 172 hp. per cubic foot of free air per minute, making a total of 688 hp. required at the compressor to produce 200 hp. at the machines. At $30 per horse-power this would mean $20,640 per year. Stated in another way, the electric line loses only 78 hp., while the air line throws away 488 hp., which means that the loss, if air line were used in place of electric, would be $12,300 per year, a sum sufficinetly large to practically pay the original first cost of the electric wiring. This may seem large, but these calculations show the air transmission to be only about 40% as efficient as the electric transmission system.

PUBLICATIONS RECEIVED

Any of the books noticed in these columns are for sale by, or can be procured from, the Mining and Scientific Press.

Year-Book for 1908. Illinois State Geol. Surv., Bull. 14. Pp. 394, ill., index. Urbana, 1909.

A general report on the work of the Survey followed by special papers, including: 'Report of the Co-operative Topographic Survey of Illinois', by W. H. Herron; 'Studies of Illinois Coals', by H. F. Bain, Frank W. De Wolf, J. M. Lindgren, Perry Barker, George S. Rice, J. M. Snodgrass, A. Bement, W. F. Wheeler, C. K. Francis, and H. C. Hoagland; 'Coal Deposits and a Possible Oilfield near Duquoin', by Jon Udden; 'Costs of Foraminifera in the Carboniferous of Illinois', by R. M. Bagg; 'Natural Gas in the Glacial Drift of Champaign County', by C. F. Knirk; 'Artificial Silicates with Reference to Amorphous Silica', by W. S. Williams; 'Paleobotanical Work in Illinois in 1908', by David White; 'Proceedings of the Illinois Fuel Conference'.

Engineering Index and Annual for 1909. Pp. 471. The *Engineering Magazine*, New York, 1910. Price $2.

This is the annual compilation from the 'Engineering Index', published monthly in the *Engineering Magazine*. The Index proper is preceded by a classification which will enable the user to quickly find articles on subjects of interest to him.

The Mississippi Valley Between Savanna and Davenport. By J. E. Carman. Illinois State Geol. Surv., Bull. 13. Pp. 96, ill., index, maps. Urbana, 1910.

Another of the 'educational bulletins' in which the State Survey is attempting to make geology plain and serviceable to the people of the region discussed.

Geology of the Elizabethtown and Port Henry Quadrangles. By James F. Kemp and Rudolf Ruedemann. New York State Museum, Bull. 138. Pp. 173, ill., maps, index. Albany, 1910.

This bulletin is of especial interest to students of iron ores, aside from its local value.

Mining Industry of North Carolina During 1907. By J. H. Pratt. North Carolina Geol. & Econ. Surv., Econ. Paper 15. Pp. 176, ill. Raleigh, 1908.

A general account of the occurrence and production of minerals in the State, with a special report on mineral waters.

Weathering of Coal. By S. W. Parr and W. F. Wheeler. Univ. Illinois, Eng. Exper. Station, Bull. 38. Pp. 43, ill. Urbana, 1909.

Results of experiments, series of 1909, continuing the work described in Bulletin 17.

The Scientific Press.

A Journal of Science, Art, Manufactures, Chemistry, Inventions, etc.

VOL. I. SAN FRANCISCO: THURSDAY, MAY 24, 1860. No. 1.

THE SCIENTIFIC PRESS

IS PUBLISHED WEEKLY,

BY GEO. H. WINSLOW & CO.

Office, 172 Washington Street, over Atwill's.

TERMS OF SUBSCRIPTION—For 1 year, mailed to any part of the State.....$4 00
For 6 months, " " " " 2 50
For 3 months, " " " " 1 75

TERMS OF ADVERTISING—10 lines, or one square.....for one insertion.....$2 00
20 " two squares..... " " 3 50
Considerable reduction made to permanent advertisers.

PROSPECTUS.

THE People of California will be pleased to learn that the publication of the above named Weekly Periodical has at length been undertaken, and that the first number will be speedily issued. There is much latent genius in this State, whose discoveries and inventions would prove valuable, both to Professional men and Mechanics; but for the want of a proper exponent, such discoveries and inventions must remain hidden.—The Publishers have undertaken to become this exponent, and will issue a Weekly Periodical in octavo form, to be called the SCIENTIFIC PRESS, to appear every Saturday noon.

The columns will be solely devoted—

I. To the interest and advancement of the Mechanic and Working Man; to instruct them in all that is useful and advantageous to their Trade or Profession, and inform them of all the latest and most approved discoveries in Science and Art.

II. To advance, encourage and protect "HOME MANUFACTURES." The ruinous system heretofore existing in this State, of sending away on an average $2,000,000 per steamer needs reforming. This State possesses sufficient raw material, with eager hands to labor to transform the same into fabrics. San Francisco, the great Emporium of the Pacific, can and will furnish the coast north and south, as well as the interior, with all the necessary implements.

III. Inventors of useful Machinery and Instruments, will find this the only medium in this State wherein their claims for Patents may be successfully prosecuted. It is therefore requested, that those interested should at once leave with us their plans, drawings and models, with explicit specifications, and such other information as they may possess relating thereto. The Publishers have made arrangements with an able and successful law firm at Washington, as well as in this city, who will, at moderate fees, prosecute the claims of patentees, both in the United States and Europe. The Publishers will attend to all transactions pertaining to the sales of Patent-Rights either here or on the other side of the Pacific and Atlantic. We shall also keep a record of all New Patents entered, as well as those whose term has expired.

IV. The Publishers will give a history of the rise of our Manufacturing Establishments, a complete synopsis of the number of hands employed, articles manufactured, as well as the *modus operandi*, and such other particulars, with illustrations.

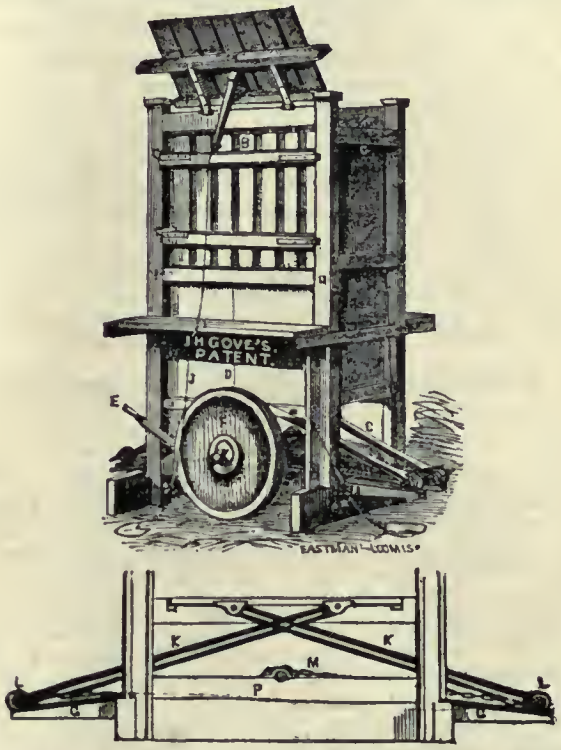
The "*Scientific Press*" will be edited by several able and acknowledged writers, whose Philosophical and Scientific acquirements stand pre-eminent here and abroad, who will also reserve to themselves the right of criticizing the Drama, Literary and Musical productions.

The Publishers will issue five thousand copies as a beginning, which will be sent to all parts of the State and Oregon, the Atlantic States and Europe.

GEO. H. WINSLOW & CO.,
Proprietors.

READ THIS!—The *Scientific Press* will give every week a treatise upon all the arts, science, trades, and manufactures, which will not only be entertaining but vastly useful. These articles will be written by the most talented men in this State, who have kindly volunteered, and whose literary acquirements stand pre-eminent, combined with a practical and theoretical knowledge of the subjects they may treat of, which will not fail to create the most intense desire for every issue.

J. H. GOVE'S PATENT HAY PRESS,



Our readers will be gratified to learn, through our first issue, the existence of a Patent Hay Press, invented by Mr. J. H. Gove, of California, for which he obtained a patent from the United States Government in March, 1860, through his agents, Messrs. Wethered & Tiffany, of this city. Patent-rights are now being sold to Counties for $1,000—Solano County being the first to purchase a right. The patent is issued for the usual period, 14 years, No. 27,361, the particulars of which will be found on another page of the *Press*. Arrangements in the Atlantic States for the sale thereof have been effected. The superiority of this machine over others, is amply testified by numerous notices from the press, as well as by certificates from those who have purchased and used it. This machine may be properly termed a combination of the Railway and Lever Press (See cut and diagram.) We congratulate California, and the inventor, Mr. Gove, upon this important labor-saving utensil; may he reap the reward he so justly merits.

It is estimated that this machine can press from twelve to fifteen tons of hay per day, with three laborers and a pair of horses. Mr. Gove has personally worked at the rate of two tons of hay per hour, in this city, making them in bales weighing from 275 to 350 lbs. to the bale, thereby pressing 100 lbs. more hay—contained in less space than a common 200 lb. bale, which naturally enhances the value of the hay—is more desirable for shipment, and creates less wastage. For further particulars, we refer our readers to the patentee, Mr. Gove, or his agents in this city.

(A). The top lid, as shown open, has a cross-bar which serves to be fastened by loops thrown over each end; which connected by means of rods running to the bottom of the press contracting the pressure from the levers (K) in diagram.

Printed at the Commercial Steam Book and Job Printing Establishment, 129 Sansome Street.

(B). The front door, slatted corresponding with the back of the press, he apertures being for passing ropes or wires for the tying of the bale.

(C). An end door, which retains its position by catches on the inside of door (B), and when (B) door is thrown open, end door (C) recedes enough to allow the bale to be extracted easily.

(D) The follower of the press to which are attached the upper end of the levers (K) in diagram, also slatted to correspond with the door (B) and lid (*a*), allowing the ropes or wires to pass under the bale.

(E). Is a ratched pall-lever which serves to throw off the pall from the ratched wheel for the purpose of lowering the follower to its original place.

(F). A groved wheel containing a rope or chain propelled either by manual or horse power, is attached to a center shaft upon which the chains (M) wind in diagram.

(G). In diagram, are iron rails upon which the grooved or flanged wheels (*l*) move, and form parts of levers.

(H). Are the levers or arms forked on the lower end, within which are placed wheels (L), connected together by a cross-bar.

(M). Are chains connected with the cross-bars at the forked ends of the levers (K), thence to center shaft (P), to which shaft the power wheel (F) is attached—thereby winding the chains around the shaft, bring the lower ends of levers (K) together, which forces the follower with great power upwards, until the arms or levers are raised nearly perpendicular.

(I). A rope running in grooved power wheel (F) for the purpose of working the press.

(J). Another rope attached to a lever on top lid (A) for the purpose of opening and shutting the same in filling and pressing.

(K). The levers or arms (K) are so constructed with forked ends, that one pair of them pass each other at right angles at the top, which principle insures greater force and power than heretofore attained.

To the Mechanics and Manufacturers of this State.

Actuated by the noblest motives, and the period being quite propitious—we have resolved to enter upon the labor of publishing an advocate and exponent in your behalf. We say labor, because much requires to be done before the chief ends of your business avocations, rights and privileges are achieved. The abuses heretofore existing in this State, with reference to the workingman and laborer, need strenuous efforts for improvement. Heretofore, but a meager attempt in manufacturing has been carried on, and if any, only such articles which were for immediate use. In consequence of this and the fluctuating times prevalent in this State, the leading manufacturing establishments never have kept any number of hands for an extended period in their employ. The causes are obvious, as every mechanic who has been here but a short time knows. The State being yet in its infancy has therefore demanded but little; the price for labor has necessarily been too high—and, as a general thing, the market has been overstocked. These are some of the chief causes of the mechanics' want of success. To these may be added the want of the requisite material and machinery.

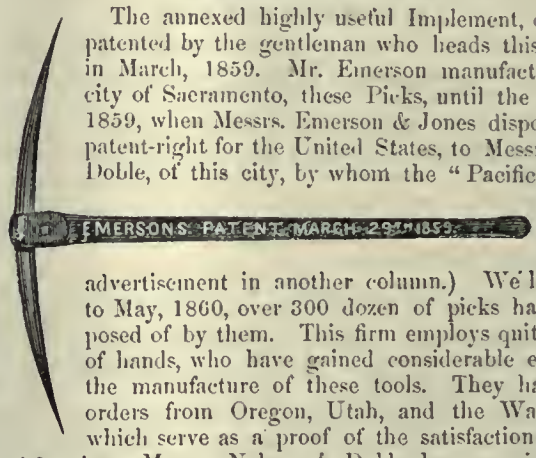
But California has, for its extremely short existence as a State—a matter of ten years or more—created and executed more than perhaps any other State in the Union, or elsewhere. Backed by an indomitable and go-aheadative spirit, possessing more enterprising, and the shrewdest business men that can be found on this globe, she possesses a *literati* for every science and profession. She has also established permanent institutions for the prosecution of the resources of the State, numerous libraries, free schools, and private academies of learning. We have wandered somewhat from our subject, for the reason that what we are about to assert may be more firmly established; it is this: "*We predict that California in less than ten years will be a manufacturing State, notwithstanding the fabulous gold and silver fields with which she is forever haunted and constantly kept in a hot fever.*" The mechanic and laborer have been induced heretofore to search for the precious metal. Some have found it; the most of them had better remained at their workshop. Their hard-earned dollar would have realized tenfold its value in a more permanent investment, such as tools and machinery, real or personal estate, than in purchasing fictitious mining claims, thereby becoming the innocent dupes of unprincipled speculators.

We wish at the same time to be understood, that we do not refer to the actual miners—because they, perhaps, are devoid of a profession or trade—or to capitalists or owners of established mining fields—they can and do find sufficient laborers to work their respective claims.

We cannot deny that it is due to her immense auriferous wealth that California has achieved her great renown in the world; but we consider that the time has now come when her other immense resources should be worked into fabrics and utensils. Capitalists could not find a safer or more permanent and paying investment. The facilities for exportation are not only extensive and accessible but particularly lucrative and profitable.

The shipments of nearly two millions of dollars bi-monthly, would thereby be materially reduced; instead of the money going out of the State, it would help to establish an exporting community, and would give thousands of eager hands who seek our golden shores, employment. Trade would assume a healthier aspect, and be established more permanently. Losses by shipments would be avoided, and the system of monopoly in articles heretofore sent to us and none manufactured would not be heard of; to say nothing of the time lost in waiting for the arrival of merchandise, freight, and the interest of the capital invested in the meanwhile.

J. E. Emerson's Eyeless Pick.



The annexed highly useful Implement, or Pick, was patented by the gentleman who heads this paragraph, in March, 1859. Mr. Emerson manufactured in the city of Sacramento, these Picks, until the 1st of July, 1859, when Messrs. Emerson & Jones disposed of their patent-right for the United States, to Messrs. Nelson & Doble, of this city, by whom the "Pacific Tool Company" has been established. (See advertisement in another column.) We learn that up to May, 1860, over 300 dozen of picks have been disposed of by them. This firm employs quite a number of hands, who have gained considerable experience in the manufacture of these tools. They have received orders from Oregon, Utah, and the Washoe mines, which serve as a proof of the satisfaction which these picks give. Messrs. Nelson & Doble have received from the Committee of the last State Fair, a very high recommendation accompanied with a silver medal. For further particulars we refer our readers to Messrs. Emerson, Nelson & Doble, 89 Pine street, in this city.

Engraving on Glass.—We translate from *L'Invention* the following account (by Mr. Gugnon) of a new process of engraving on glass, for printing the patterns for embroidery, netting, crotchet, etc., by which it is said that the labor of a month in this kind of engraving can be performed in one day. The process consists in etching by means of hydrofluoric acid which, as our readers are aware, has the remarkable property of corroding glass:

1. *Substances Employed.*—It is known that certain fatty and resinous substances are not soluble in hydrofluoric acid. Among these substances the author chooses the bitumen of Judea, to which he adds one-sixth part of gum mastic (mastic in tears); he then reduces the whole to an impalpable powder.

2. *The Design.*—The design is cut in stencil, either in paper, parchment or metallic plate, in a way to cover those portions of the glass which are to be attacked by the acid, and to leave exposed those parts which are not to be attacked.

3. *The Application of the Process.*—The glass is placed horizontally, and varnished with a very thin coating of any fatty substance (the author prefers the essence of turpentine); and the stencil plate is laid on the varnish while it is fresh. The asphaltum powder is then sifted through a very fine sieve over the surface of the stencil plate and the glass, and the plate is carefully removed, thus leaving the powder upon the glass in figures corresponding to the open parts of the plate. The glass is next exposed to gentle heat, which causes the essence of turpentine to combine with the asphaltum and the gum mastic, and the mixture, in melting, fixes itself to the glass.

4. *Treatment by Acid.*—The pattern is surrounded by a ridge of soft wax prepared for the purpose, and hydrofluoric acid, diluted with one-third its volume of water, is poured over it. In about forty minutes the etching is completed.

EDITORIAL.

The Fulfilment of the Years

On May 24, 1860, the MINING AND SCIENTIFIC PRESS was founded at San Francisco. This issue is published 50 years afterward and celebrates a half-century of technical journalism. We cannot claim the antiquity of *The Spectator* nor that of *The Times*, but it is our privilege to be the oldest mining journal on the American continent. However, age in itself is nothing to boast of, unless accompanied by usefulness. Whether the MINING AND SCIENTIFIC PRESS has performed useful service during the past 50 years is for our readers, their fathers, and their grandfathers to say. All we can state with confidence is that the editors and managers of this paper have done their best, and that they have been rewarded by the increasing support of a host of friends scattered all over the world. To these friends it may prove interesting to recall the changes of control that have given a varied but consistent character to the paper. The first publishers of the *Scientific Press* were Winslow & Company, a firm whose active representative was J. Silversmith. He was succeeded in 1862 by W. B. Ewer and C. W. M. Smith, who in turn gave place, December 14, 1863, to Dewey & Company. Thus Alfred T. Dewey became identified with the MINING AND SCIENTIFIC PRESS, the addition to the name being significant. For 30 years he di-

rected affairs. In June 1893 J. F. Halloran bought control and retained it until December 1905, when he sold his interest to T. A. Rickard, who also became editor.

If long life be the reward of good conduct, the editors may take that unction to their souls, for it is a pleasure to state that nearly all of them are still alive and well. Almon D. Hodges, Jr., who was editor from 1869 to 1871, is now an honored citizen of Boston; Charles G. Yale, who edited the paper from 1871 to 1893, is statistician to the U. S. Geological Survey in San Francisco; and W. H. Storms, who was in charge between 1897 and 1905, has just published a valuable textbook on mine timbering. During shorter intervals Dr. Henry De Groot, E. B. Piper, J. D. McGillivray, Clarence S. King, and R. L. Dunn served in an editorial capacity. During his management Mr. Halloran also supervised the reading matter, and when he resigned the ownership became incidental to the editorship.

In the business department H. F. Dexter, a nephew of Dewey, is still on deck after 32 years of faithful service, and John J. Young, the chief of the composing room, has performed a service much more than mechanical for 27 years. Elsewhere the editor who was at the helm during the troublous days that followed the earthquake-fire of 1906 gives an account of the way in which the M. & S. P.—as it is known to its friends—was rehabilitated after a great disaster, and the story makes it evident that the spirit of true journalism united the entire staff and linked every member of it in loyalty to the traditions of an institution the spirit of which no physical disaster could destroy.

Fifty years is not much to the geologist, it is a brief period to the philosophic historian, but in California it is an age. In 1860 the Comstock Lode had just been discovered, the Civil War was about to begin, placer mining had reached its zenith, but vein mining had barely begun. In a feeble way smelting had been attempted in California. The existence of showy deposits in Calaveras county, as stated by Mr. L. S. Austin in this issue, led to the development of a metallurgical industry, which with some vacillation has continued to the present day. It is amusing, however, to note that the metallurgist of that period was content with, or resigned to, a capacity of eight tons of ore per diem for each of two blast-furnaces. As early as 1870 water-jackets were in use at the works mentioned at Copperopolis. Reverberatory smelting was also attempted at Antioch, a town now languishing at the junction of the Sacramento and San Joaquin rivers. This location illustrated thus early the necessity for placing reduction works at tidewater near the commercial focus of California. Today the Selby Smelting & Lead Company's great works on San Francisco Bay show how insistent was that demand, and how well it was answered. Near it are the works of the Mountain Copper Company, where advanced methods introduced by Mr. Lewis T. Wright, enable copper smelting to be conducted in the midst of a thickly populated district without offense or protest, the sulphur fume being reduced to commercial acid by the chamber process and used in the conversion of phosphate rock to the soluble form. The Peyton Chemical Company is also smelting copper ore and concentrate of gold-bearing pyrite, on San Francisco Bay, producing contact-acid from the sulphur fume. It is interesting to observe that in 1860 the era of machine work in mining was just dawning. The rich placers had hitherto furnished material from which to extract fortunes by hand methods. The rich ore-shoots on the Mother Lode and the northern gold-belt of California admitted the winning of profits by the application of home-made machinery of medieval design. The period of economy in operation, favored by the application of the principle of division of labor, was just beginning for the miner. But there had been a strong incentive to development. Just such enormous reward for comparatively small expenditure of capital was needed to awaken a nation to the possibilities its Continent held for yielding wealth from mineral deposits. It emboldened the pioneer; it gave faith; it drew to the task the men of stronger nerve and brain. These men went forth from the western fringe that had been dominated to the further conquest of a great interior that held opportunity, not greater than those men dreamed, for they were endowed with imaginations kindled by the gold of California, but as great as they hoped, though in a different way. Rich streams of golden gravel like those of the Black Hills, and elsewhere, though overwhelmed with greedy hordes of fortune-seekers, were only incidents in the later unfolding of resources that meant the subduing of a wilderness to the purposes of civilization. Witness the Comstock, which after a whirl of unrestrained excitement has become the basis of mining that will endure longer than we can now foresee! Witness also the enthusiasm at Butte when rich silver ores inflamed the minds of the early comers, who have been followed by the orderly multitudes who are winning millions of pounds of copper each year under the guidance of mammoth companies whose life will extend far into the future. The immense industries of Colorado have grown up within this epoch of fifty years, and Arizona, now threatening to become the premier mining region of America, was still unwrested from the Apache at the beginning of that period. The art of gold dredging has been evolved as a means for recovering the precious metal even from gravel of low tenor, and the cyanide process has revolutionized the metallurgy of gold and silver, while copper matte is now 'blown to blister' in a few hours, and then electrolytically refined, whereas a half century ago the slow and costly reverberatory process was used, producing at best only an impure grade of metal unless the original ore was of exceptional quality. And who, looking back upon this, can doubt that in the next fifty years even greater progress will be made? In that progress technical science will play a dominant part, and it will be the privilege of technical journalism in general, and of the MINING AND SCIENTIFIC PRESS in particular, to inform, to help, to guide the captains of industry under whose creative hands enterprise will flourish and commerce expand. No vividness of imagination is needed to picture the growth of the communities dwelling on the Pacific Coast of North America; the Panama

Canal is being built; the centre of population trends westward, the path of empire has halted, the Orient meets the Occident at the Golden Gate, the MINING AND SCIENTIFIC PRESS is published at the cross-roads of the world.

Time was when this paper looked only to local support and concerned itself only with local industry. During Mr. J. F. Halloran's régime the field of usefulness was enlarged so as to cover the Rocky Mountain region, but since he yielded control, in December 1905, the scope of the paper has been further enlarged so as to cover metal mining throughout the world. Nothing is alien to the MINING AND SCIENTIFIC PRESS that concerns the miner. The name lays emphasis on the mining and then on the scientific aspects of the great search for minerals. The paper was started when mining meant digging holes into the ground, and it has lived to see the application of modern science in every department of a world-wide industry. In 1906 a motto was adopted: "Science has no enemy save the ignorant." We may also say: Mining has no friend like Science.

In bringing science to the every-day aid of the miner, it has been the privilege of technical journalism to be the agent of transmission, to be the bearer of the knowledge that gives light underground and to carry the tools that give a tenfold strength to the hand of man. That has been the mission of the M. & S. P. for fifty years; that will be its mission in the years to come.

Our Motto*

A good wine needs no bush and a suitable motto should require no explanation. Nevertheless, it seems fitting at this time to give reasons for the faith that is in us. "Science has no enemy save the ignorant." It is a true saying and worthy of all acceptation. Time was when the mariner cut down the oak and made him a vessel wherewith to cruise the seven seas; he depended upon the fickle wind to propel his ship and he steered by the light of the stars. As he fared forth across the main and began to make traffic over the waste of waters, he found the need of something stronger than the old wooden boat, something more certain than the stars. His brothers took the iron from the earth and gave him steel to sheathe his ship, they dug the coal from which he drew the throbbing energy that furrowed the wave, they made him a compass whose trusty finger should point a path when the storm curtained every star. Navigation became a science and naval construction an art. So also to those who go down to the mine in skips; to them Science gave tools, energy, and a light wherewith to illuminate the dark places in the earth. The simple digging of ore was well enough so long as the miner did not penetrate far from the daylight, using pick and spade to move the mineral, applying his muscle to carrying the product of his toil and the sight of the ore as the guide to his advancement. But as he burrowed farther, these simple ways did not suffice, he harnessed the horse to his windlass and made a whim, he yoked the oxen to the cart that carried his ore, he compelled the torrent to turn a wheel and drain his hole in the ground. Then, penetrating to a depth greater than the height of the tallest trees, he found simple mechanical methods began to fail, he called on Science for help, for further he could not go alone. Aid was given abundantly. Steam replaced muscle, steel replaced wood, and engineering took the place of rule of thumb. Far from the day-light he penetrated into the adamantine heart of the earth, until he walked in galleries a mile beneath his dwelling.

But even that was only a beginning. Science sharpened his tools with the diamond and quickened his operations with electricity. And then with faithful hand and trusty word, she told the miner how to separate the waste rock from the valuable mineral, the dross from the metal. Metallurgy became an art. Nor was this the end, Science did more; in every department of his manifold operations she breathed a system which crystallized into a great industry, orderly as the arrangement of a crystal, smooth as the working of a machine. The prospector became a geologist, the miner became an engineer, the hole in the ground became the basis of a business that supported a vast community. And yet the story is not told, for Science became more than an aid to work, she became a companion in pleasure, a guide, a philosopher, and friend. As the piece of ore is converted to burnished silver, so the old common sense was transmuted to a trained intelligence ready to cope with every problem in life. Man went forth to conquer, first nature and then himself. Self-reverence, self-knowledge, and self-control led him to sovereign power. Therefore, as a child to its mother, as a patriot to his native land, so he who mines the ore, who wins the gold, refines the silver, or smelts the lead, turns to the fairy who has blessed his going forth and his coming home; he honors her ways, which are ways of truth, he follows her light, which suffers no eclipse; and to those that follow he says. "With this sign shalt thou conquer: 'Science has no enemy save the ignorant.'"

*From MINING AND SCIENTIFIC PRESS, July 7, 1906.

SAILORS have from the early days of mining in the West contributed their share to the growth of the art. The rope-splicer has always been in demand for hoisting works, and no one can repair a rope better than Jack Tar. The early ropes, of course, were all made of hemp, and the sailor was consequently dealing with familiar material. The Pompeian initiative in using the wire rope was not followed until comparatively recent times, after mines had attained great depths. Mr. Joseph McGillivray reminds us that sailors found much employment during the days of the Argonauts in the sewing of canvas into pipes for hydraulic mining. Though gold miners have taken to building fleets for dredging, the sailor has not found his training to have fitted him for service in their manipulation, but not long ago, when a gold dredge at Oroville needed radical repairs to its hull because of the wear of the stern against the ever present pile of sand-tailing it required a crew of sailors to show how easy it was to clap a caisson on the end of the boat, and renew the worn out part without stopping the work.

TWO pages from the first issue of the SCIENTIFIC PRESS, the predecessor of the MINING AND SCIENTIFIC PRESS, are re-printed in this issue.

TYPE used in printing this paper from 1866 to 1870, inclusive, was made by Faulkner & Son, and included the first font cast in California.

WITH this issue of the MINING AND SCIENTIFIC PRESS we will have furnished our readers with 67,554 printed pages. Their appreciation of the material that has filled those pages is indicated by the growth of the paper from 8 to 212 pages in size. Increase at the same rate through the next fifty years implies a volume of nearly 6000 pages for our Centennial number. This will involve difficulties which we gladly leave to our successors of that date.

MINE RESCUE work is likely to receive great impetus from the organization of the new Bureau of Mines. Mr. Frank Mondell, of Wyoming, has introduced in the House a bill appropriating $200,000 for additional stations for instruction of miners, and other similar bills are under discussion. The progress which has already been made in providing equipment for fighting gas and mine fires is vividly shown by the account on another page of the attempt in 1889 to fight a fire in the Idaho mine, by using divers' helmets.

EDITORIAL responsibility has been but lightly assumed in preparing this issue, and the blue pencil has been held back when the temptation was strong to bring all to conformity with the present style-sheet. Much of the flavor of the old pages lies in the form of expression adopted, and in reprinting them we furnish illustrations of the change in style that the years have brought. Adjectives, as bonnets, have their day of popularity and the style of writing of a half century ago is as archaic as the style of dress.

AMONG the papers formerly published by the proprietors of the MINING AND SCIENTIFIC PRESS was a *Ladies' Home Journal*. We are not informed that it ever attained the circulation of Mr. Edward Bok's justly celebrated Philadelphia publication of the same name, but we judge from certain paragraphs which strayed over into the columns of the PRESS that it was at least as interesting in spots. When the *Ladies' Home Journal* was a member of our family the editor of the PRESS could always fill awkward spaces in the forms with recipes for biscuit and other items important to bachelor miners, by 'lifting' copy from his associate.

THE CALL for an International Gold convention at Denver, in July 1897, mentioned in 'Concentrates' this week, brings to mind that this was the beginning of the movement which resulted in the formation of the American Mining Congress. The growth of the latter in membership and influence has shown that there was a real need for the organization. Plans for the Los Angeles meeting of this year are now being made and everything points to an unusually large attendance and an important session. The recent passage of a bill to create a Bureau of Mines at Washington is a distinct triumph for the American Mining Congress, which has been foremost in its advocacy.

ALASKA in 1860 was practically unknown to Americans. Mr. W. P. Blake's account of what he saw there in 1863 will, therefore, be read with special interest. His original report was reviewed in these columns at the time it was published, and in 1868, on the return to this country of Mr. W. H. Dall, a long account of the geography and geology of Alaska was published. The map printed on page 766 is from this account. The contrast between this and the maps now published by the United States Geological Survey is striking. In later years the MINING AND SCIENTIFIC PRESS has kept in close touch with Alaskan development, and aside from the special correspondence we have published from there, our readers will recall with especial interest Mr. T. A. Rickard's articles on the Yukon country and Seward Peninsula.

CONCENTRATES appeared as a department in this paper June 9, 1894. Long before that, however, short practical paragraphs such as especially characterized that department were a feature of the paper. At first they were used to fill out the pages following longer contributed articles. Later a special column was devoted to 'Coast Industrial Notes', under which heading were run miscellaneous news items, personals, commercial paragraphs, and the material now classified as 'Concentrates'. These notes were usually placed near the end of the paper. In 1893 they were given the title 'Mining Briefs' and placed next the Editorials, taking on at the same time something of the nature of editorial paragraphs. In the same year the names 'Tailings' and 'Slickens' were used for awhile, but eventually 'Concentrates' was chosen and has since been used.

ORE GENESIS is a subject of study that has made especially notable progress in the last half century, as will be realized by those who read Mr. S. F. Emmons' account in this issue of the prevailing theories fifty years ago. His article is but a portion of a long and valuable discussion of the development of theories of the formation of ores, that we expect to publish in full at another time. J. D. Whitney, to whom Mr. Emmons devotes considerable space, was one of the first great American mining engineers. His fame is indissolubly associated with both the Mississippi Valley and the Pacific Coast, and despite certain errors which have been much exploited by critics, his work was of high order and of basal importance. Joseph Le Conte, whose activities were in the period immediately succeeding that which is here discussed by Mr. Emmons, was also one of the men who did much to promote geologic work in California. It is worth while to recall that as early as 1871, in an article published in the MINING AND SCIENTIFIC PRESS, he announced his belief that veins were due to (*a*) deposition from solution; (*b*) that the solutions were hot; and (*c*) that they were alkaline; a quite modern theory of ore deposition. 'Professor Joe', as he was lovingly called, did little work,

however, as a mining engineer and made his main impress as a teacher. To the men of the Geological Survey must be conceded the largest influence in developing the present theories of ore deposition, and among them Mr. Emmons, as for many years the geologist in charge of investigation of metalliferous ore deposits, was largely influential.

Stamp-Milling

No attempt has been made to review in this number the development of milling processes during the last fifty years. The evolution of the California stamp-mill has been lightly treated, merely to show the controlling influences. The fact needs to be borne in mind that the California stamp-mill was an adaptation to ores which as a rule contained coarse gold. In many cases the amount of concentrate available was entirely negligible, or the extra recovery by finer crushing was insufficient to warrant the added expense. Hence California practice settled down to moderately coarse crushing in shallow mortars, admitting of high capacity. The Californian, however, looked upon his mill as an amalgamating quite as much as a crushing device. This involved attention to the details of the 'splash', so as not to scour the inside plates, and that in turn made standard the 5-stamp battery, which admits of the most uniform distribution of the ore within the mortar, and of the least violent wave-motion of the pulp. At the same time it placed a limitation upon capacity. The high duty which, at first thought, one might anticipate with mills having a discharge height of from two to four inches was not obtained because of the need of maintaining conditions favorable for amalgamation. The great capacity reported from South Africa, reaching 9 tons per stamp per diem, could not, of course, be attained if inside amalgamation were practised. The California mill, doing its allotted work, often crushed 5 tons per diem, though 3½ to 4 tons was nearer the average. This was accomplished by using screens ranging from 20 to 30 mesh, and stamps weighing about 800 pounds. On the Rand the screens used are as coarse as 12 mesh, and the stamps weigh from 1600 to 2000 pounds. There is no marvel in the Rand stamp-duty when these conditions are taken into account. It merely represents a change in method; the adoption of a two-stage instead of a one-stage crushing process. If it paid better to provide more batteries and crush finer, instead of to crush coarse for tube-milling, or if it proved more economical to crush coarse in one battery, and to finish in a second, that would be done. The modern African stamp-mill is probably more economical of power than are mills where inside amalgamation is employed. The great weight of the stamp results in less masking of the blow. The resiliency of the die is better realized, and crushing is accomplished less by abrasion and more by reaction after impact. Experiments, however, show no important variation in the screen analyses of the pulp produced under the two systems.

It is noteworthy that during this same period another distinct type of stamp-mill was evolved in Gilpin county, Colorado. The existence of ores heavy with pyrite, and containing free gold locked in the sulphides, necessitated either crushing for concentration only, or crushing fine for amalgamation. Transportation costs worked against shipment to smelter, and the Colorado miner discovered that by using a deep mortar a selective action was obtained, the gangue being promptly discharged, while the heavy sulphides were retained longer and became more finely crushed. This involved slow speed to facilitate settling of the heavy particles, and the high drop led to the use of light-weight stamps. A tendency today, when finer crushing is found advantageous in so many cases, and when cheaper power admits of the economic application of more energy than could be consumed in the past for crushing alone, is toward the deepening of mortars without reduction in the weight of the stamps. The stamp-mill, which is nothing more than the modernized primitive mortar and pestle, seems to be both elemental and eternal. It refuses to be displaced, and its evolution continues. It is not inefficient, and it is the most flexible machine for comminution of ores ever devised.

The American Mining Law

The complexity and diversity of the law relating to mines in the United States is comprehensible only by knowledge of the historic reasons underlying its growth and development. The original colonies inherited the 'common law' of England, and the general rules of law governing the operation of mines and quarries and their tenure became part of the jurisprudence of this country. The regalian doctrine that the crown was entitled to all mines of precious metals was of no practical importance to the original States, because comparatively little mining outside of coal and quarries has been carried on in them. Another cause operating to prevent the creation of a radical system of mining jurisprudence in those States was the absence of any 'public domain'. They and not the Federal Government owned all land within these original thirteen States.

As soon as new territory, owned by the Federal Government, was added it became necessary for Congress to pass laws providing for its control and disposition. The necessity for the enactment of mining legislation arose with the acquisition of zinc, lead, and copper lands on the public domain in some of the States of the Middle West. In the early part of the last century a system of leasing the mineral lands of the public domain was instituted, but in 1847 this was abandoned, the years of its operation having proved it to be 'radically defective'. The Acts of 1846, 1847, and 1850 provided for the outright sale of mineral lands, "and laid the foundation of a more substantial prosperity," to quote the Presidential message of the time.

With the acquisition of the vast territory included within California, Colorado, Oregon, Nevada, Idaho, Montana, Wyoming, Utah, New Mexico, Arizona, the Dakotas, and Washington, and through the discovery of the precious metals, a new era in mining began. It was here that the 'American Mining Law', so-called, had its birth. It was a unique growth, an in-

stitution that was characteristieally American. It resembled in its origin the principles of democratie government that were the outgrowth of the old New England town meeting. Hordes of people of all nationalities, but predominantly Anglo Saxon, rushed to the new El Dorado. The Mexican law of mines previously in foree had been abolished by military proelamation. Some sort of law was imperatively necessary, otherwise individual might, and continual shedding of blood in the lawless attempt to establish rights, would have been the inevitable result. It rested with the Federal Congress to pass such laws, since the mining took place on the public domain. But Congress was many weeks' journey distant. The States might have aeted in the absenee of Federal legislation, but neither the Federal Government nor the States saw fit to enact a code of laws. To fill the void the miners legislated for themselves; they organized mining distriets, met in convention, and passed their own governing laws and rules. This was turning back a page in history to the parliaments held by the tinners of Devon and Cornwall, eenturies previous. In time these rules came to have a remarkable uniformity. Later they were recognized by the eourts and the legislatures of some of the States. From the diseovery of gold in 1848 until the Federal Act of 1866 the acquisition, control, and mining of mineral lands in the West was carried on entirely in aeeordanee with the rules and customs of miners as established in the mining districts.

Various aets providing for the control and disposition of the mineral wealth of the West have been suggested from time to time. There was a plan to lease on a royalty basis, and the idea of paying off the enormous publie debt inherited from the Civil War by this means met with great favor in the East. The long failure of Congress to aet on this question was probably due to a fear on the part of the Western interests as to what the legislative mill might grind out if the question were advanced for final settlement. Finding, however, that there was a strong tendeney to enaet some sort of legislation which might perhaps prove detrimental to the mining interests of the West, Senator William M. Stewart, of Nevada, aided by other Western Senators, drafted the Aet whieh is now known from the year of its passage as the Aet of 1866. This Aet, strange as it would seem from the early importance of placer mining, applied only to lode-claims. This was probably due to the faet that plaeer mining was on the deeline and lode-mining had reeeived a powerful impetus by reason of the discovery of the Comstock Lode. The Act of 1866 was in large part a codification of the miners' usages and customs, whieh had by that date beeome erystallized into a fairly homogeneous set of rules. It recognized what had previously been but a right of possession by sufferance, and declared the mineral lands of the public domain to be "free and open to exploration and oeeupation." The lode was the main thing granted, and the amount of surfaee territory incident thereto, and necessary for the convenient working of the lode, was left for determination in the individual eases as they arose. It also granted the right to follow the vein on its dip into adjoining ground. The Aet of 1870 provided primarily for the acquisition and patenting of placer claims. Both this Act and that of 1866 to a large degree still left the manner of locating mining claims to the local miners' rules and eustoms.

The Aet of 1872 is mainly concerned with lode-elaims. It prescribes their exact maximum limits, provides for parallelism of end-lines, and contemplates the granting of a piece of ground enclosing a vein and including all other veins found therein, and thns it subordinates the importance that the single vein assumed in the Act of 1866. These modifications were to remedy the imperfections of the Act of 1866 as demonstrated by practical experience. The Act of 1872 was so much more complete in every way that it largely did away with the necessity for the existence of the miners' customs and rules. They had served their purpose in the evolution of our mining law and were now embodied in permanent legislative form. Sinee the Aet of 1872 there has been no general Federal mining legislation of great importance. The mining laws have been extended to Alaska with minor modifications. A new code has recently been enacted for the Philippine Islands. This provides for the vertical boundary system for lode-claims, doing away with the extralateral right as far as these islands are concerned.

The eomplexity of our mining jurisprudence has been increased by State legislation. Each of the mining States and Territories has from time to time enacted codes regulating the details of location and tenure of mining claims. These supplement the basal Federal law, but are far from being uniform in character. The statutes of each jurisdiction must be consulted to ascertain the nature of its particular enactments. There are few who will not admit that our system of mining jurisprudence has many imperfections. As we look back from the vantage-point of the present, many possible improvements may be indicated, but when we consider the adverse conditions whieh surrounded its origin and realize that it was the outgrowth of the enactments and experience of the miners themselves, it compels admiration. Instead of being a code of rules imposed by men unfamiliar with the conditions to be regulated, as many unthinking critics have assumed, it proves to be the erystallization of the very customs and usages which were created by those most vitally interested, namely, the miners themselves. It is one of the most democratic products of our whole seheme of Ameriean jurisprudence.

The most unique feature of the 'American mining law' is that granting the owner of the apex of the vein the right to follow the vein to any depth on its dip, even though it pass beyond his vertieal side boundaries into adjoining land. This extralateral right has provoked severer eriticism than any other provision in the law, but the fact that the miners themselves originated and codified this idea in their local district conventions and followed it in practice for more than a deeade prior to the passage of the first Federal act whieh recognized and perpetuated it, should eause the critics to pause. It is questionable whether at this late date the advantage many think would result from the adoption of the vertical boundary system would not be far more than offset

by the added confusion and uncertainty which would result from having two inconsistent systems of tenure in virtual operation side by side, since extra-lateral rights already acquired and vested could not be abolished by subsequent legislation. Evasion of the requirements concerning annual labor, and the acquisition of 'association' placer claims on the wholesale plan by individuals, are abuses that should be corrected. Far more threatening and imminent is the so-called 'conservation' idea which is sweeping the country. While metal-bearing lands have not as yet become seriously involved in the revolutionary legislative changes which are now being proposed for governing the disposition of lands valuable for coal, oil, gas, phosphates, and water-powers, yet there are many who would include even these. There is no way of foretelling what this radical change of national thought may bring about, and the reservation by the Federal Government, and the leasing of mineral lands on a royalty basis, may be seen in the not far distant future.

Mining is attended with great uncertainty, and the prospecting for and development of ores and other minerals should receive every reasonable encouragement in the future as in the past, and the element of security resulting from a fee simple title should not be lightly sacrificed.

Gold and Prices

In modern times three distinct golden ages are recognized. The first was in the colonial days and was due to the placers of South America. The height of production during this period was reached in the middle of the eighteenth century when the average was more than twenty tons of fine metal per annum. That was four times as much as the annual production in 1492 when Columbus made his first voyage of discovery. The second gold age was in the middle of the nineteenth century. It was no coincidence that the MINING AND SCIENTIFIC PRESS was founded in the midst of this period of mammoth production. It was the need of an organ for the mining industry, stimulated by an annual output of 200 tons of gold, that called the paper into existence. On the other hand, it certainly is a coincidence that the golden jubilee of the PRESS occurs at the time of another wave of phenomenal output. Between the extremes of this fifty-year period the curve of production lay far below the maximum of 1859 and 1860. Even as late as 1890 the yield of gold in the United States had not risen to thirty-three million dollars. Last year it touched $100,000,000, representing the culmination of a growth that had been steady since 1893.

In 1860 the population of the United States was 31,450,000; in 1910 it will be approximately 85,000,000. During the same epoch the gold production of the country has expanded from about $48,000,000 to $100,000,000. So far as the United States is concerned the quantity of gold won has not been in proportion to the increase in population. Reliable figures for the population of the earth as a whole during these fifty years are not accessible, but it will be conceded that the growth of the United States has been at a greater rate than the rest of the world. On the other hand, the consuming power of the individual for commodities has enormously increased through elevation of the standard of living. In Africa alone within ten years it is estimated that 50,000,000 negroes have abandoned the simple Adamic costume for garments made of imported cotton. In all parts of the world the demand for staples has increased at an enormous rate. The annual gold output of the world has risen from 200 to 950 tons in 50 years, constituting a ratio of 1 to 4.75. Mere figures of population are of little value for comparison with the gold output, since the demand for gold in exchange depends upon the consuming power per individual. This has risen both absolutely and relatively among nearly all races. The growth of this consuming power in the world has certainly been as great as the increase in population in the United States during the last fifty years, and that has been at the ratio of 1 to 2.7. The wheat crop has increased in the last forty years in the ratio of 1 to 2.4, while the ratio of population-increase has been as 1 to 2.18. In the same period the pig iron production has grown in the approximate ratio of 1 to 8. This is a measure of the increase in the production of other metals as the output of wheat is a measure of agricultural development. The disproportion sustains the contention we have previously made that high commodity-prices are a result of inadequate growth of the agricultural, as compared with the development of the mineral industry. This is emphasized by the enormous increase in the price of agricultural products and the low price of metals at the present time. Were high prices due in any degree to a reduced purchasing power of gold because of its abundance, the elevation should be horizontal. It is not, and the argument is fair that the present output of gold is needed to effect exchange in the hugely expanded business of the world. In 1860 the bankers were in trepidation and the economists were sounding dire warnings of evil because of the golden floods pouring out of California and Australia. But gold did not lose its value in exchange. The development of continents was stimulated by it, and all that could be won found place and need. At the close of another fifty years, confronting a remarkably similar situation, we predict that the subduing of new lands in the enormous areas yet untouched in Canada to our north, and in Latin America to the south, the reclaiming of enormous areas of swamp and wooded land in the Southern States and of desert land in the West, and the opening of Africa to colonization, will produce effects analogous to those following the great gold output of half a century ago. While the world has opportunity for pioneering no fear need exist of a surplus of gold, and he who has traveled thousands of miles through the almost unpeopled areas of South America, with its tens of millions of acres of rich but unused lands, has a strong impression that pioneering will not be over even in several epochs of fifty years. The economist who undertakes to explain so complex a phenomenon as the present high cost of living by charging it to the medium of exchange has not penetrated deep into the problem.

Twenty-Three Years a Mining Editor

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES G. YALE

It was merely force of circumstances, not choice, which made me become an editor of the MINING AND SCIENTIFIC PRESS in 1871, though I continued to hold that position for 23 consecutive years and until the old firm of Dewey & Co. sold the paper. I was really being trained to become a mining engineer, when the death of my father necessitated my seeking immediate employment in the city, so my active mining career ended.

Among others to whom I then applied for suitable work was Albert Hart, librarian of the law library. He knew W. A. Skidmore, who was at that time acting as California assistant to Rossiter W. Raymond, the United States Mining Commissioner. Mr. Skidmore mentioned to Mr. Hart that Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS, were looking for a young man "who was college bred and knew something of mining," to act as assistant editor. I called at the office, was accepted, and went to work at once; all without the slightest possible knowledge of an editor's duties. This was the force of circumstances I speak of, that stopped my career as a mining engineer before it really commenced, and fixed me on the editorial tripod 'for keeps'. I have been an editor on various technical and daily papers ever since, besides following other occupations connected with mining. It was only on January 1 of this year that I finally laid down the editorial pen and retired from that field, after inflicting many thousands of columns of all sorts of printed matter on an unoffending public. In palliation I may say, however, that I probably blue-penciled and condensed, or 'killed' altogether, more pages of manuscript than I ever wrote.

In looking back now it seems to me I have been all my life in the midst of a great mass of manuscripts and 'exchanges', clipping into some and cutting into others. There has always been more of that kind of work to do than actual writing, as far as my experience shows. My old friend Arthur McEwen, one of the best writers ever on this Coast, after all sorts of vicissitudes, finally became managing editor of the San Francisco *Examiner* at a large salary, but resigned the position after three or four months. I remonstrated with him for his foolishness, and he gave me as the reason that he thought he was put into the world to write, which, as an editor he had no time to do. Instead he had daily to put out of existence, by his blue pencil, column after column of what others had written. It went against his conscience, and he became a free lance on the weekly and daily papers with much a smaller income.

When I became assistant editor under Warren B. Ewer he had been editing the MINING AND SCIENTIFIC PRESS and the *Pacific Rural Press* both for a month or two, and was glad to get an active and energetic young 'sub', though an inexperienced one. A. D. Hodges, Jr., his very capable assistant and virtually the principal editor of the MINING AND SCIENTIFIC PRESS, had shortly before resigned, and they had not been until then able to find a successor. It was with some fear and trembling that I took his place, knowing his superior acquirements and facility with the pen, but there was no choice; I had to do it. Mr. Ewer set me to work clipping the exchanges, making up the mining summary, reading proof, and hunting up things, and on the second week I proudly presented to him my first carefully written editorial. I do not now remember its import, but I recall that I used a Latin expression, to show my erudition doubtless. This he promptly cut out, explaining that mining people did not understand Latin, and it was bad form anyhow to use it in ordinary newspaper work. That settled my Latin quotations forever after.

The MINING AND SCIENTIFIC PRESS was in those days a very different paper from what it has been of late years and is now. In the first place there were only 16 pages weekly, including advertising matter. Moreover, there was very little original matter of a technical nature printed, the editors depending almost entirely on scientific journals published elsewhere for material of that class, and printing it under classified heads or departments. These departments were made up by Mr. Ewer, and consisted of condensed articles on different subjects, but none of them original. Some were re-written from clippings, but there was no pretense of original investigations. It is to be remembered in this connection that the PRESS in those days catered to the working miner and not at all to the engineer or skilled superintendent. California was filled then with men who were prospecting or mining, and there were comparatively few incorporated companies with large works and plants, and not one-tenth of the men working for wages that there are in these times. One of our most popular departments was 'Domestic Economy' wherein were given receipts and hints on cooking and such matters, all much appreciated by the hundreds doing their own domestic work in the mining camps. It took several years hard urging later on to get Mr. Ewer to abandon this department as too undignified for a technical paper, but it served its turn in its day, as was noted by the complaints from certain old-time subscribers when it was finally dropped.

For a number of years after I joined the paper, they continued the custom of sending the made-up forms outside to a job-printing office for printing. The man came for the forms with a hand-cart at 7 a. m. every Friday, and they just had to be ready for him sharp on time. This occasioned strenuous work late on Thursday night of each week, and we usually did not leave the editorial rooms before 2 or 3 o'clock on Friday morning. Often we remained until the man came for the forms. The force in the composing room was comparatively small, with a smart foreman and one good 'ad' man. Dewey & Co. issued other papers, notably the *Pacific Rural Press*, and work on the 'Scientific' as we always called it, was often put off pretty late. In those years a large part of the income of the paper was derived from the delinquent sale advertisements, resulting from pub-

lished assessments of the Comstock and other Nevada mines. Some of these sale 'ads' took up one or two or three pages of small type and they often came to the office late on Thursday afternoon, so that work upon them had to be done in the composing room at night. They were put in hand at once and often not a stick of type was set on editorials or mining summary before 10 p. m. on the day prior to the forms being sent to press. The reading of proofs and revises therefore, on the 'second' or editorial forms was necessarily done at night. I have, times without number, gone to the office at 7 a. m. on Thursday and left at the same hour the next day. I can see now that this was not necessary but the system, or lack of it, prevailing called for these duties at the time. It was some ten years after I went on the paper before plans were adopted which did away with night work in the editorial and composing rooms.

The firm was not in a position, or thought it was not, to pay for contributions to the columns of the paper except on rare occasions. The editors had to depend on occasional contributors, or on the 'traveling correspondents' sent out into the mining camps to obtain subscriptions and advertising. These men sent back letters describing the camp and the mines which had generally to be re-written entirely in the office. One of the first things I was set at when I came to the office was to put in shape a dozen or so long letters from the Montana mining districts written by W. H. Murray who was a 'rattling good' solicitor but a poor letter writer. Mr. Ewer had dodged editing this so-called manuscript. The notes were written on all sorts of paper, and sometimes all around the white margin of a newspaper. I had to take a map and follow Murray around to fix 'where he was at' while writing. He got lots of subscribers, but it was hard to make readable matter out of his 'stuff'. Murray is still alive, and still in the same old business in another State.

Another solicitor who wrote many letters in his day was the late L. P. McCarthy who was with the firm of Dewey & Co. many years. He called himself a statistical writer, his statistics usually consisting of stating the exact distance of a camp or town from San Francisco, from a railroad depot, the number of inhabitants, and so on. A mine was so deep, had so many feet of drifts, tunnels, etc., employed so many men, and was discovered at such a date. The compositors used to say that they had to 'sort up' their cases with capital I's when 'Mac' was on the road, he used the personal pronoun so often. He was on one occasion sent to write up in the old-fashioned way the Comstock Lode and its mines. An arrangement had been made with Adolph Sutro, of tunnel fame, by which he had placed the Gargantuan order of 10,000 copies of the M. & S. P. for this series of letters, and they had to be done pretty well to satisfy him. As soon as 'Mac' left on his mission I fortified myself by obtaining all the literature available about the Sutro tunnel and the Comstock mines. Then, when his manuscript arrived I found it had to be all re-arranged and virtually re-written. I simply wrote the letters in the office, using such of his facts as I could, and offering the subject in as fair shape as might be. 'Mac' was always proud of those letters, and never in any way resented the liberty taken with his manuscript. Another 'outside man' we had later was an Englishman with a decided thirst, who in about every so often would go on a spree for several days. He was a very useful man, and Mr. Dewey did not like to discharge him. He was finally made to sign an agreement with the firm that if he got drunk again in the State of California he would forfeit $500. After keeping straight for a longer period than usual, he disappeared and was not found for a week. He turned up in Portland, Oregon, where he had gone by sea for his regular spree, but as he did not have it in California, he forfeited nothing. Mr. Dewey was much astonished at being out done by this unexpected ruse.

Perhaps the most annoying thing in connection with my editorial work for many years after joining the paper, was the trouble about obtaining engravings. We had to have at least two illustrations each week, and it was always hard to get one good one. Engraving then was all done on wood, and electrotypes made from the wood-cuts for use on the press. I can never remember a time when we had engravings for two issues ahead. A three-column cut cost somewhere near $100, and we seldom had any made when we could obtain them from catalogues, or other sources. New mining machinery and inventions were our strong suit, and the inventors or manufacturers paid for their own cuts. We also obtained many plates from Government publications, the American Institute of Mining Engineers, and others, but the idea of illustrating as fully as is done now was never dreamed of. We were forced to use all sorts of things for illustrations, many of them being entirely out of keeping with the character of the publication. It was not until about the nineties that we began to get many decent illustrations. Notwithstanding this difficulty in the matter of engravings Mr. Dewey was constantly starting new publications, most of them being illustrated. He had an unfortunate fad of starting new papers or buying out old ones, greatly to the financial detriment of himself and the firm, and to the annoyance of the editors. He seldom got a new editor for these papers, so those of us already there had to take the added task. I gave at my home in Oakland a dinner to the 'office' on the occasion of the twentieth anniversary of the firm of Dewey & Co.,—not the paper—and arranged a souvenir composed of headings of all the papers Dewey & Co. had started up to that time—that is, all I could find. The list surprised even Dewey himself, and 'there were others'. Many of these were papers devoted to the interests of fraternal orders and with one exception—*The Watchman*—they were all more or less unprofitable.

The most detested of these papers to me was the *Mechanics' Fair Daily*, printed for a month or six weeks of each year during the continuance of the annual fairs given by the Mechanics' Institute. Its contents consisted mainly of 'write-ups' of exhibits, and it was hard work, indeed, to get up a paper like that every day for a month or two and to make it in any way interesting. In fact that was impossible, but the paper was a pet of Mr. Dewey, and some-

times made money. I had to edit it in addition to my ordinary duties, and in fact, I had often to neglect the ordinary duties. Another rather unpleasant duty weekly was to 'write up' the foundries and machine shops of the city. I had to visit these in rotation, interview the proprietor, and describe anything of interest in their shops. With a big piece of machinery I would often find part in the molding room, part in the machine shop, and part still in the draughting room. Taking the specifications and seeing such parts as I could, the descriptions were made. We derived a large income from foundry 'ads', and this advertising of the shops was gratuitous on the part of the paper. We obtained much that was new, and kept in advance of mining machinery orders in this way. Moreover, we obtained also the first call on many 'cuts'. I became rather skilful in this kind of work, so much so, that in later years, when the large foundries wanted machinery described in the daily papers, I was often employed to prepare the articles, and was paid for it. This sort of writing was also useful when I had to prepare specifications for a year or two in the patent department of the firm later on.

It may be here noted that San Francisco was in the seventies and to some extent in the eighties, the principal place in the United States for the manufacture of mining machinery, especially for large plants. At that period it had no rivals. Agents for 'ready to use' mining machinery were hardly known. This city had for a market the States of California, Nevada, Utah, Colorado, Oregon, Washington, Idaho, Montana, and Arizona. The mechanical ore-feeders, originated here, as did the hydraulic nozzle, the Pelton water-wheel, and a dozen other notable things, and the best quartz milling practice was known to be that of California. Mine pumping-plants were also important things for the local foundries. Mining men from all parts came here to obtain what they wanted for their enterprises. For these reasons the foundry business had an intimate connection with the publication of the Mining and Scientific Press. The foundries and machine shops all advertised in it, and all considered it their special journal. For some years a special column of 'Foundry Notes' was run, containing items of special importance.

It may be mentioned, incidentally, that shortly after I came on the paper as assistant editor, Mr. Ewer dropped all editorial writing, and never took it up again. I had to write the editorials, make up the mining news summary, edit correspondence, provide engravings, edit manuscripts, make up the market reports, and those on stock transactions, and do all the work on the paper with the exception of the 'departments' which Mr. Ewer continued to carry on. There was no assistant, and when I wanted a vacation I had to provide a substitute. That substitute was for many years the late Dr. Henry De Groot, well remembered by all old California mining men. He was a frequent contributor to our columns on mining topics. He was a pioneer miner, and was the first newspaper man to interview Marshall, Wimmer, and others at Coloma after the discovery of gold in California. He did this as correspondent of the New York *Herald*. Dr. De Groot was the best posted man on general mining affairs, who could write, that I ever met. He had been to all the 'excitements' on the Coast, and had visited all the mining camps. He was a keen observer and could describe what he saw excellently. For many years he wrote for various papers on mining topics. The late Almarin B. Paul was another who wrote often for the Mining and Scientific Press. He had a fad on saving fine gold, among other things, and he wrote much on that subject. Charles H. Aaron, author of several books on assaying, which were published by Dewey & Co., was a frequent contributor to our columns. So was the late Henry G. Hanks, the first State Mineralogist, who wrote on the assay of gold, gold in black sands, borax, minerals of California, etc. Melville Attwood, the geologist and noted gold miner, was a frequent caller at the editorial rooms, and often wrote for us. Amos Bowman, who preceded Mr. Hodges, a former editor of the M. & S. P., sometimes sent in articles. W. A. Goodyear, author of 'Coal Mines of the Western Coast of the United States'; Guido Küstel, author of 'Concentration and Chlorination'; C. A. Stetefeldt, inventor of the Stetefeldt furnace, and J. S. Phillips, author of 'The Prospector's Companion', were also occasional contributors to our columns.

The prestige of the Mining and Scientific Press was great in the mining communities of the Pacific Coast, and many attempts were made to dislodge it from the place it had attained. I can recall a dozen or more mining papers which were started in San Francisco to take away the business of the Press and take its place. None of them ever succeeded. They thought the Press too old-fashioned and conservative, and that its proprietors had no enterprise. This was to an extent true, but the Mining and Scientific Press had established itself firmly in the favor of the mining communities where it circulated and could not be displaced. In this connection I may say that I confess to surprise that the paper did not lose caste entirely for a period during the agitation about hydraulic mining, and when injunctions were issued which resulted in closing down mines of that character in the drainage basins of the Sacramento and San Joaquin rivers. This question brought about a very decided antagonism between the miners and the farmers of the State. The firm of Dewey & Co. published the *Pacific Rural Press* as the organ of the farmers, and the Mining and Scientific Press as the organ of the miners. Obviously there was a difficulty in this situation. Neither paper had much to say on the subject and indeed ignored it as much as possible. I was given strict orders by the head of the firm to write nothing on the subject of hydraulic mining, to put in the paper only 'official news' about it, and to show him any items about to appear. Here was an unpleasant situation for an editor, to be muzzled on the very topic most of all interesting to the community that his paper was supposed to represent. Many a savage letter did I get, and many a personal growl from prominent mining men, for the course I was taking. For hundreds of these men knew me personally and did not know either Mr. Ewer or Mr. Dewey. The latter dominated the firm and its policies, Mr. Ewer being something of an in-

vertebrate, with no opinions opposite to those of Mr. Dewey, or at least none that he advanced. He was a kindly old gentleman and an excellent associate, but he often aroused my anger by his way of dodging questions and of taking no side nor giving an opinion. Mr. Dewey's sympathies were with the farmers, so the MINING AND SCIENTIFIC PRESS was suppressed as far as hydraulic mining was concerned.

The position taken by the paper on this subject injured it materially, no doubt, for the suppression of hydraulic mining resulted in the closing of many such mines, and almost the entire depopulation of some small camps and communities. It was not until the paper was sold to Halloran and Holman that its editor was allowed to speak freely on the question of hydraulic mining. Just about that time a convention was called by the miners of Placer county, at Auburn, to take some steps for the rehabilitation of hydraulic mining, and I was sent to report the proceedings. I was one of those who drew up the appeal to the people of California and to assist the hydraulic miners, and I happened to be the only mining representative from the city of San Francisco to the convention. I was by that body appointed a committee of one to try to organize the movement in San Francisco, and to get the daily papers in line to help the miners again. On my return to the city I was fortunate in getting the active assistance of my young friend William C. Ralston, and between us we managed to arrange a meeting of a few prominent mining people and we organized the San Francisco Miners' Association of which I have been the perpetual secretary. We also got the daily papers to accept articles which I wrote on the subject of the condition of the hydraulic mining industry. The result of these efforts was the organization of the California Miners' Association. At the first convention of that body I, as editor of the MINING AND SCIENTIFIC PRESS, was appointed to represent the miners, and Robert Devlin to represent the anti-débris men, and we together drew up the memorial to Congress adopted by the convention, which resulted in the passing of the Caminetti law permitting hydraulic mining to go on under certain conditions. The law has not had the good effect hoped for, but it certainly permits hydraulic mining where it was not permitted before.

I was allowed by the proprietors of the paper to say whatever I thought should be said about hydraulic mining, and I was not curbed in any manner. I took this chance to put the 'old Scientific' back into its proper place as a friend of the miner in this State, which it had almost lost by the policy adopted by the former proprietors.

Among other departments which used to be in vogue with us was that of 'Answers to Correspondents'. This was a big nuisance to me sometimes, as conundrums were propounded which it took a good deal of looking up and running around to answer. As I had succeeded Mr. Hodges as editor of the paper, so I had succeeded him as secretary of the California Academy of Sciences, a position I held some 16 years. On scientific topics, therefore, I had good advisers. On mining topics, geology, mineralogy, and those connected with machinery, etc., there were plenty of able men I could consult with. It turned out, however, that a large number of the questions related to mining laws. A new mining law was passed by Congress, May 10, 1872, and we have it yet. Before that everything was done under the crude law of July, 1866. My father, Gregory Yale, had written the first treatise on mining law published in the United States, 'Legal Titles to Mining Claims and Water Rights in California'. To that work I had contributed some Spanish translations, and a glossary of mining terms, the first of that sort published, I think. When the law of 1872 came into effect the miners were puzzled by its terms, and it became one of my editorial duties to answer questions on the subject. I had to make mining law a study, and consult books and lawyers so that I became quite expert on that subject, and was considered rather an authority, though a layman. I did not have any Judge Curtis H. Lindley to help the paper out on mining law questions in those days, so I had to make a study of it myself.

It may be confessed, however, that the paper during the period while I was its editor, never became the authority it has since, nor was it at all to be compared in literary or technical excellence with its present standing. Mr. Halloran improved it in many ways, and may be said to have 'put it on its feet' financially and to have made it valuable. T. A. Rickard, however, bringing to it his editorial genius, his wide knowledge, and his acknowledged standing in the mining world, has done more to make it an authority in a scientific way than any man connected with it since I knew it. There is no comparison between the paper now and what it was twenty years or more ago. Its present editors and proprietors are men whose names alone would give it standing equal to any others did not their work every week prove this beyond doubt. It is now a world paper, whereas in my day it was quite a provincial one, confining its activities to a limited sphere and not employing technically skilled men to conduct it. While I was the editor of the MINING AND SCIENTIFIC PRESS for the long period of 23 years, and have since been connected editorially with other technical journals, I should now hesitate some time before accepting a chair in its editorial rooms were I asked to do so.

The editors have asked me to write some reminiscenses and I have done so hurriedly, as is my wont. I am told that your old foreman, my good friend John Young, said when told I was to contribute to this special edition: "You'll get Yale's stuff if he promised it, but you' ll get it late"; and he was a true prophet. He has had experience of me in the old days. But we always went to press on time, even if my yachting and other sports unduly interested me, and I never made him wait for 'copy'. If this copy is written late and comes late it is only through my usual habits of long standing; and such habits give no time for revision or for careful writing.

Quick Time.—The steamship *Rising Star* arrived in New York on the 8th inst., with passengers from San Francisco, Nov. 19th—the passage having been made in the short time of 19 days and 21 hours!—December 14, 1867.

Rambling Recollections of an Old Sixty-Niner

Written for the Mining and Scientific Press
By A. D. Hodges, Jr.

It was the golden age of California when, in 1869, I became junior editor of the Mining and Scientifc Press. It was the age of simple, comfortable living, hopeful happiness, and unstinted hospitality. The mines were yielding annual dividends of 25% or more. At least, when a mine was offered for sale, if the examining engineer could not report that it would probably return the purchase price in four years, his clients refused to buy. This was the general rule among those whose regular business was mining.

There was a class of these mining operators, with headquarters at San Francisco, which is now extinct. They could be seen any week-day on Pine street, dabbling in stocks and ready for a good mining investment. The majority had worked in the mines where they had accumulated a capital sufficient for their wants. When one receives 25% interest, a large capital is not needed for the simple life. Many of them had pleasant homes across the bay, and it was their custom to invite thither, to spend Sunday, half a dozen to a dozen guests, who were then regarded as members of the family and given the freedom of the place. Did you desire to give a ride to a charming young lady, whom you, perhaps, had met for the first time, it was merely necessary to order the hostler to harness up a rig. Everything on the place was at your disposal. With these men it was "easy come and easy go," and they generally spent all their income in free-handed hospitality. They lasted until the days of the Bonanza stock speculation which wiped them out. Pre-eminent among those practically engaged in the extraction of gold from the ground was the drift-miner. What a brave, generous, independent optimist he was! How capable and intelligent! The whole tribe of miners was fine, and it was a joy to sojourn with them in the wonderfully beautiful Sierra region. But the drift-miner excelled.

Many of the Argonauts were still on deck, and their achievements had inspired the later comers. Some of them lived chiefly in the past. These were the ones who were wont to lead you to a street corner and, pointing to a large building, tell you how they had once owned the land there, and if they had only held on to it, instead of selling it for a song, they now would be rolling in wealth. A much larger number was prosperous, vigorous, and enterprising, and welcomed heartily those who had come to aid in the development of the Coast. The pioneers, while proud of the commonwealth which they had builded, still retained strong affection for their native hearths; still talked of going 'back home' to live—some time. Emperor Norton was still existent, but in rather a decadent state. No longer could he sell his bonds, redeemable when he should be seated on his throne in Mexico. Every morning, dressed in his plumed hat, brass-buttoned blue coat, and gray trousers, bearing a bottle of beer which some still loyal subject had given him, he entered Sorbier's restaurant, laid a 'short bit' on the counter, and was served with a full meal—the regular price here being a bit a dish. The Gutter Snipe still prowled about the streets, refusing to accept anything which had not been first thrown into the gutter whence he extracted it. And those two large dogs (Bummer and Lazarus) still had the freedom of the city.

San Francisco had the best cheap eating houses in the world. There were excellent French, German, Spanish, Italian, and American restaurants, each with its specialty, where dinners of at least three courses cost 25 to 50c., wine included. The swellest places, the Poodle Dog and the Maison Doreé, as well as the first-class hotels, charged one dollar; and for $10 a week the best hotels offered four meals daily: breakfast, from 6 o'clock a.m. to about noon; lunch, from noon to 2 or 3 p.m.; dinner, from 6 to 10 p.m.; and supper, from 10 to midnight. If hard up, or very economical, you could get a clean, abundant dinner at the What Cheer House for ten cents, the payment of which sum entitled you also to the use of the comfortable, well-stocked library where you could read, chat, and smoke until midnight. A bedroom, with clean sheets, was obtainable here for 25c. a night. The flower-girls were a feature of the restaurants. At dinner time they came around with their bouquets which cost two bits; unless holding a camellia, when the price was four bits. These girls did not verbally solicit custom, but a new-comer or a regular customer often found a pretty flower laid silently beside his plate.

As a rule wages were good and the number of house-owners in San Francisco was remarkably large. Old lame John, waiter in the two-bit Clay Street Restaurant, confessed to owning two houses, which he rented, besides the 'shack', as he called it, where he and his wife resided. The poorest paid individuals seemed to be the laborers in the fields of literature and art. San Francisco was not then a literary or an artistic paradise. It was related of a certain rich man, who was building a large and expensive residence, that he and his wife declined to purchase some genuine 'old masters' because they "didn't care to have any second-hand pictures in their new house." There was no public library (the Mercantile Library, however, was most liberally administered) and no art museum. In addition to the many bright journalists, there were artists, who, failing to sell their pictures which were not then in demand, contributed articles on all subjects to the papers whenever they could get them accepted. Thus the market was overstocked. My primary wage was $16 a week, sufficient to enable me to live decently and put something in the savings bank. When I finally received $150 a month, my income exceeded that of all but a few of my brethren. Nevertheless it was a bright and jolly brotherhood, a genuinely Bohemian brotherhood of the pen and the brush. Anyone writing the early history of the Bohemian Club of San Francisco would needs tell how many members, in the days of which I speak, paid their dues in the shape of witty entertainment and artistic production.

A. T. Dewey was manager of the PRESS during my term of service. He had an ambition to be known as the publisher of many papers, and accordingly launched numberless ephemeral publications with the general result of crippling the resources of his chief journal. He was also prone to changes in the make-up and even the name of his papers. Yet he clung tenaciously to certain features inappropriate to a technical journal. He was a newspaper man of experience in small towns, but as manager he failed to take advantage of the opportunity to increase the influence of his best publication. However, he had many fine qualities, and I hold him in affectionate memory.

The senior editor was W. B. Ewer, a charming associate. He had been in journalism from youth, and had edited papers in both the East and the West. He had lived in the mining regions and understood well the mining conditions of the Coast; but his greatest delight was in agriculture, and he had always desired to edit an agricultural paper. When at last his wish was fulfilled and the *Pacific Rural Press* was founded, he devoted himself to this paper and turned over the charge of the MINING AND SCIENTIFIC PRESS to his junior. My predecessor was Amos Bowman. I have often wondered how he was able to abandon the profession of journalism to which he seemed so well adapted. He was a man who knew something of everything, and had been in many parts of the world. At one time he was a reporter on the New York *Tribune*. Then he spent a year or so in Russia as an attaché of the American legation. He studied mining for a year at Freiberg, Saxony, and art for a year at Munich, Bavaria. When I arrived in San Francisco I found him on this paper. The State legislature met that winter and he was engaged by the Sacramento *Union* to report the proceedings in full. He invited me to hold down his editorial chair during the legislative session. When the session ended he decided not to resume his position here, and I retained the place. George H. Strong, graduate of Dartmouth and mechanical engineer, was at the head of the patent agency owned by Dewey & Co., and closely affiliated with the papers. While not officially on the editorial staff, he was constantly aiding the editors in the subjects of mechanics and mechanical engineering. He was our most valued 'special contributor', although he did not bear any such label. Perhaps the term 'cheerful contributor' would have been more appropriate, for his presence always brightened the editorial rooms. Dr. William Barstow was in charge of the department of Mechanical and Scientific Progress. He was a full-fleged M. D., and those who knew him, considered him a very skilful practitioner. But he abounded to such an extent in kind-heartedness and diffidence that he was never able to render a bill for services performed, and hence was obliged to seek other sources of income than his professional practice. He was a scholar in a wide field of knowledge, and his work on the paper—at ten dollars a week—was excellent.

Of all those connected with the paper, McCarty and Murray had the most numerous acquaintances. They were our canvassing agents for the interior and traveling correspondents. McCarty was irrepressibly optimistic as to the power of the press when he was soliciting. He once promised that, within a year or so, we would have a railroad built up through Mendocino, Humboldt, and Trinity counties, to places where at the time there was only a weekly stage, and that uncertain; and our circulation in those regions increased mightily. Had we done all that McCarty declared we could do, we should have built a network of railroads throughout the Coast and crushed the Central Pacific. I had frequent discussions with him, but his enthusiastic imagination was unrestrainable.

Murray was quieter and steadier but equally persuasive in his work. He once landed in a camp, where few, if any of the miners could read. Not daunted by this he showed them the pictures and induced a number to subscribe on that basis. He was a faithful correspondent and sometimes his letters in spots ran thusly: "Mr. Editor: I arrived last Monday in this district which is favored so wonderfully by the God of Nature. I have been surprised to find, in addition to many developed mines, such an abundance of brilliant prospects which, through the efforts of the highly intelligent miners, are bound within a very short time to pour out a steady golden stream. You may rely—say, old man, you've been here and seen this place. So whoop her up the best you know how. Every miner in the vicinity has subscribed, some for two years, and all have paid in advance. Hank Smith, who runs a *first-class* hotel, has taken six copies. He says he knows you and I think you really ought to give him a bang-up mention." Murray occasionally dropped into poetry, and the editing of his stanzas, which he sometimes requested, strained the resources of the staff.

We sought to make our editorial room a centre of the mining industry of the Coast, and succeeded in a measure. The principal miners and engineers visited us occasionally and told us of their operations. They were all very busy men and it was extremely difficult to obtain written articles from them, but now and then fortune favored us. Almarin B. Paul, Guido Küstel, C. H. Aaron, Charles A. Stetefeldt, and Dr. Partz were, I think, the most frequent contributors. Whenever Mr. Stetefeldt and Dr. Partz met in the sanctum, we expected an earnest and entertaining discussion, carried on in characteristic German fashion in the German tongue, as to whether that certain mineral was designated properly Stetefeldtite or Partzite. The editors of papers published in the mining districts, with all of whom we exchanged, often made calls. And every man on the Coast with an eccentric wheel in his head came and showed how his machinery worked.

I had come to the Pacific Coast to be an engineer, not a journalist. I had come prepared to find the mining world eager to secure my valuable services, and I was uncertain whether to demand, say, twenty thousand dollars a year as my initial salary, or to be philanthropic and accept only fifteen thousand for the first twelve months. I was accordingly surprised to find that what I had considered my high qualifications—a college degree and a four-year

course at the best mining academies—were simply *dis*qualifications. I was treated kindly by those to whom I applied for employment—at *any* salary, finally—but nobody needed me. People welcomed me to a seat at their generous tables, but not to a situation at their mines. As they expressed it when frankly confidential, what they wanted was "a practical man and no damn theoretical cuss."

They were right in part. They had suffered severely from glib-tongued imposters calling themselves scientists and pretending to be graduates of Freiberg. But they seemed to me rather too liberal in the extent of their condemnation. However, as I did not succeed in altering the country's custom in this respect, I decided to adapt myself to it, and at the first opportunity worked in a silver mill as pan-charger—at two and a half dollars a day and board. It was a strenuous job, twelve long hours daily, but I stuck to it. Before a full month had passed I was accepted as a practical man, and thenceforth my services were in demand.

THE IDAHO MINE FIRE

The attempt of the men in divers' armor to extinguish the fire in the Idaho mine was unsuccessful. They went down the shaft twice. At the 900-ft. level the candle went out and the electric light showed a thick smoke, but they found no difficulty in breathing, the supply of air through the hose and into the helmets being good. Near the 1000-ft. level the cage was stopped. The heat was very great and the helmets became very hot. The rubber around the wrists softened. The signal to hoist was given and the men were taken to the surface.

Several reasons are assigned by the men for their failure to accomplish anything. The pump which supplied them with fresh air was, unfortunately, situated at the mouth of the 700-ft. level, and consequently the air was vitiated and impure to such a degree as to be absolutely poisonous. Again, the provisions made in a diver's submarine suit for disposing of the air after it has been deprived of its life-sustaining properties are altogether regulated by the pressure of the water upon the rubber suit. As the surplus air expands the rubber the water pressure releases a spring, which opens a valve and allows the foul air to escape without admitting any water. In the Idaho mine the clothing of both Page and Tucker became bulged out with the impure air, the atmospheric pressure being inadequate to release the spring, and consequently both men were compelled to open the valve themselves and take chances on the poisonous gases which surrounded them effecting an entrance. Some idea of the heat experienced may be formed when it is known that one of the eye-glasses of Page's helmet was cracked. Had it broken, his life would have paid the forfeit. They are satisfied that their experiment will be of value, as it will cause scientists to endeavor to discover some material from which diving suits for mine fires may be manufactured. As far as possible air has been excluded from the lower levels. The stove plan for burning charcoal and generating carbonic gas has been abandoned and a furnace for the same purpose has been built. This comprises an iron shell six feet in diameter and lined with brick eight inches deep. At least a week will be required for surcharging the mine with carbonic gas. Then the gas will have to be expelled before workmen can go down into the depths. If bad caves have occurred, many weeks will elapse before the 200 employees will again be at work.—MINING AND SCIENTIFIC PRESS, June 15, 1889.

TRAVELING FOR THE 'PRESS'

Written for the MINING AND SCIENTIFIC PRESS
By W. A. SCOTT

My connection with the MINING AND SCIENTIFIC PRESS began in 1896, when J. F. Halloran was at the helm. His ambition was to extend the circulation into all the mining States of the West, as well as those of the Pacific Coast. I began in Colorado, and during the six years of my connection with the publication under Mr. Halloran's management its circulation in Colorado, Utah, Idaho, Arizona, Oregon, and Montana increased until we were in the lead. Machinery salesmen, who traveled among the mines of those States, came back to their houses with the announcement that they saw it everywhere, and that mining men, millmen, assayers, and engineers were swearing by it. After that advertising came easier. Mr. Halloran was a ready writer, an enterprising publisher, and a diplomatic mixer. He possessed the adaptability necessary to 'jolly' the prospectors, advise with the mine operators, and fraternize with the machinery men. He and I each thought the other peculiar, but we got along amicably. He wrote me long letters filled with both approval and criticism. He was given to jesting, and sometimes would talk in parable. He visited me once in Denver and together we called on some of the prospective advertisers. Among others I introduced him to an ore-buyer, to whom he said in a soft voice which was not altogether natural: "If you have any advertising for us you'll have to talk to Mr. Scott, as I spend most of my time on subscriptions." In those days the Denver machinery houses were forging to the front and the most of them used the advertising columns of this paper liberally. Hendrie & Bolthoff, the Mine & Smelter Supply Co., Colorado Iron Works, Denver Engineering Works, and the Leyner Engineering Works Co. were among those who gave substantial recognition to the merits of the PRESS as an advertising medium.

In 1898 I secured over 800 new subscriptions in the inter-mountain country. The list in Colorado rose from 60 to 600; in Utah it advanced from 30 to 300, and the increase was nearly in that proportion in Arizona, Idaho, Montana, and Oregon. Cripple Creek, San Juan country, Creede, Park City, Tintic, Mercur, Butte, Sumpter, Bisbee, and Clifton were each visited and at each many new subscribers were obtained.

In general I have observed a remarkable growth of technical journals since 1896, and have noted the constantly increasing number of those who read and loyally support them. Readers of those journals are becoming more exacting and critical concerning the matter they contain, which only serves to emphasize the necessity for high standards.

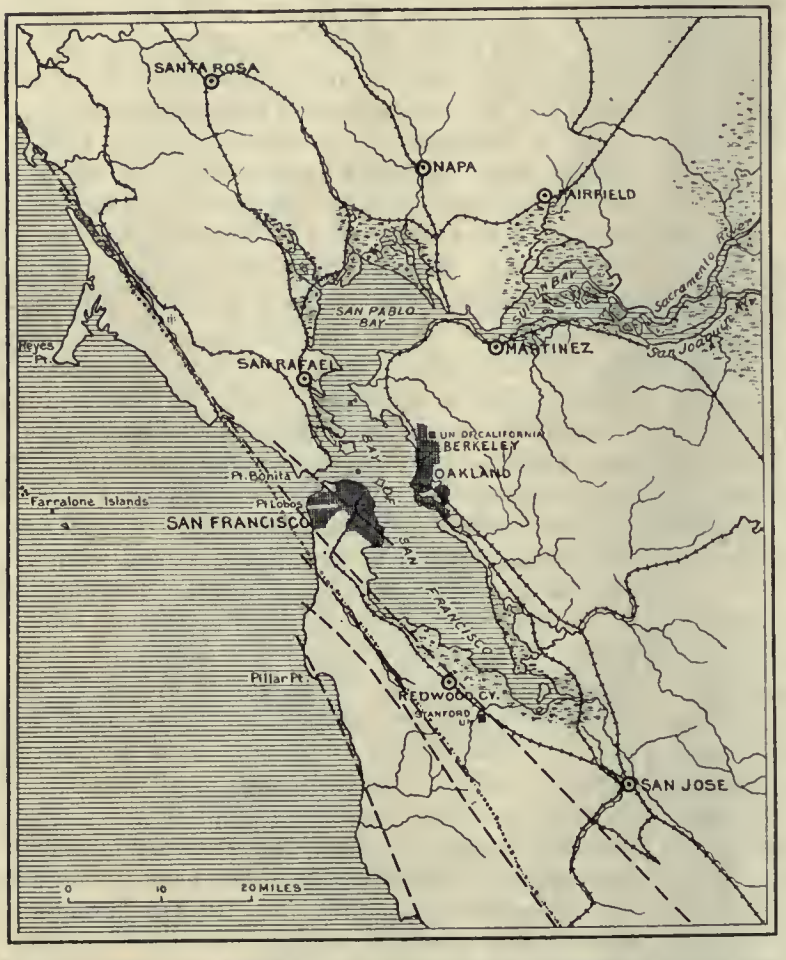
The Earthquake-Fire

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD

When the MINING AND SCIENTIFIC PRESS attains its centenary, and the editor at that later day turns back to the past record of a paper that in 1960 will be a growing educational force in a still more highly advanced community, he may mention my name as the man who happened to be in charge at the time of the earthquake of April 18, 1906. It was my privilege to be at the helm during a period of stress and trouble. Now that the horror of a great catastrophe is almost forgotten, I can look back upon those strenuous days four years ago and enjoy the retrospect. It was a great experience, and one that I would not have missed, however undesirous of repeating it. All experience that is not searing or debasing is enriching. Times of peril and periods of disorganization such as befell San Francisco in 1906 afford opportunity for an intimate knowledge of mankind, which is then tried as metal in the fire, exhibiting the pure gold of essential manhood freed from the slag of mere brutishness. We who dwelt on the Bay of San Francisco when the earth trembled and the fire raged had a chance to see human nature with the clothes off, to note the ape and tiger of the primeval savage, and to recognize the superman in his conquest of nature and circumstance.

The story of the MINING AND SCIENTIFIC PRESS, and of the men associated with it at that time, may be told, in the interest of those who will be celebrating a centenary 50 years hence. To them the event of 1906 will be the mere tradition of an episode buried under greater events, such as the completion of the Panama Canal, the political regeneration of California, the municipal reformation of San Francisco, and the progressive development that shifted the industrial supremacy of the American continent from the Atlantic to the Pacific.

At 5:13 in the early morning of April 18, 1906, I was rudely awakened by the shaking of the bed in my home at Berkeley. At once I recognized the symptoms as evidence of an earthquake and assured my wife that it was "only an earthquake, and would be over in a minute." This was not a scientific statement, for a minute means 60 seconds and that is a much longer interval than I had in mind. As a matter of fact the heavy shocks lasted for 75 seconds—and it seemed a geological period. After the first series of pulsations there was a slight decrease in the violence of the tremblings, which were succeeded by a second series of stronger vibrations, culminating in a wrench that threatened to bring down the house. Our dwelling was one of those wooden houses characteristic of California; being lined with redwood there was luckily no plaster to fall upon us, but during the earthquake the groaning and squeaking of the timbers constituting the framework of the building was deafening; it reminded me of a storm at sea. I thought the house would collapse and be thrown into the street from the hillside on which it was built. However, the idea of death was absent, we remained in bed, and through the window I could see the trees rocking. Finally the vibrations ended, we jumped out of bed and ran for the children. One of the nurses had fainted, but the entire household was soon in the lower hall, ready to run out if further quakes started.



Map of the Bay of San Francisco. The Dotted Lines Indicate Earthquake Rifts.

It was dawn; in the street were frightened men and women in night garments, talking in an excitable manner, as was natural. As no more shocks were felt, I returned to bed, and dozed until 7, my usual hour for rising. The magnitude of the event was not appreciated, but, expecting a busy day ahead, I deemed it well to get the usual allowance of sleep. Soon after rising—at 7 o'clock—we received a call from our landlady, Miss Rickoff, warning us not to light the kitchen fire, as the chimney had fallen. Luckily, we had a gas stove, which was intact. Both chimneys had been shattered and the bricks from one of them had fallen on the roof, upon an upper veranda, and then upon the wooden porch, and yet the racking of the timbers had made so much noise in the house that we were unaware that we had lost the use of our hearth. Moreover, the shaking of the house was so severe as to nauseate both children.

A Glimpse of the Old San Francisco.

one, one and one-half, and the other five years old.

Breakfast passed off without incident; at 8:10 I went on the front porch to watch the cloud of smoke that now enveloped a large part of San Francisco. Evidently the earthquake had started several fires, as might be expected. While standing on the porch I *heard* an earthquake before the house began to tremble; the sound resembled a heavy blast four or five hundred feet underground. At 8:14 another shock followed, and caused sufficient anxiety to make me undecided whether to stay at home with the family or go to the city and ascertain the fate of our offices. Just then came a telephone call from Edgar Rickard. He informed me that it was impossible to go to San Francisco.

Here I may explain that Berkeley is a university town on the eastern side of the Bay of San Francisco, which is reached by six miles of electric railway and six miles of ferry. Berkeley, Oakland, and Alameda are the bedrooms of San Francisco, from their suburban residences the businessmen cross the Bay daily to the metropolis of the Golden Gate. The office of the M. & S. P., which is known to its friends by these initials, was then at 330 Market street, at the crossing of Bush and Battery streets, in a six-story building belonging to the Crocker estate. Most of the staff lived out of town; Edgar Rickard was then at the Claremont Country Club, Oakland; H. F. Dexter at Alameda; but John J. Young's home was on Shotwell street, near Twenty-fifth, in the Mission district of San Francisco. These facts had an important bearing on subsequent events and will help to explain my narrative.

Now I revert to Edgar Rickard, who at 8:15 was at Berkeley mole; he telephoned, warning me not to try to reach the city, that the railroad and ferry service was stopped, that entrance to the city was forbidden, owing to a great fire, that he feared our office must have been destroyed, as it was in a a quarter evidently in flames, and that he would join me as quickly as possible.

He arrived at 2 o'clock. In the interval I first walked around our neighborhood and noticed that most of the chimneys were down; at the asylum for the deaf and dumb one tower had been overthrown and another badly shattered. All clocks had stopped at 5:13 or 5:14, but the damage in Berkeley was not as impressive as the big cloud of smoke that was now rising to heaven from the doomed city across the Bay. After a short stroll, however, I went into my little library and utilized the time in writing an article on earthquakes. This is the editorial that appeared in our issue of April 28. It happened that Vesuvius had been active early in March and only the day before I had received some excellent photographs of the flows of lava invading Italian villages; it was my intention to write on the subject, linking the events of a geological today with the evidence of similar occurrences in the remote past, with particular reference to the igneous rocks familiar to the miner. Thus I was primed to consider the subject of subterranean unrest and it did not take long to gather the neces-

TO OUR READERS

IN face of the calamity that has befallen the community in which we live, our own loss seems small. Our records, our library, the note-books of the editors, the manuscript ready for the printer, and the whole of the plant in our composing room, all lie buried under the ruins of San Francisco. But, owing to the customary precaution observed by two of us, complete copies of the weekly subscription lists had been taken to Berkeley, so that we possess that necessary record. Fortunately, most of the members of our staff live at Berkeley, where the earthquake was less severe and where no conflagration followed in the wake of this terrifying occurrence: As the earthquake occurred at 5:15 A. M., and the fire in San Francisco prevented people on this side of the Bay from reaching their offices, most of us were spared the horror of scenes that sear the memory. We are fortunate, therefore, as compared to many of our fellow citizens. And for other reasons. Our plant has been demolished; but this journal is built on nothing so ephemeral as paper, and on nothing so cheap as machinery; it is based upon the support of many thousand readers and subscribers who are never less likely to withdraw their support than at a time of misfortune. The goodwill of the Mining and Scientific Press is locked up in no safe, confined to no printing room; it cannot be shaken by an earthquake or consumed by fire. And, gentlemen, our friends, there is another something that is not destructible by physical misfortune or financial adversity, and that is the spirit that gives life to the printed word.

T. A. RICKARD,
Editor.

Berkeley, April 20, 1906.

TO OUR ADVERTISERS

OUR old offices at 330 Market Street, being in the very center of the most damaged section of San Francisco, have been totally demolished. We have lost our entire mechanical plant, including cuts, half-tones, type and the issue of April 21, which had already been set up; but fortunately, our complete and most recent mailing list has been saved.

We have secured ample offices in the First National Bank Building at Berkeley, which is on the east side of the Bay of San Francisco and close to the terminus of the trans-continental railroads. Through the courtesy of The Standard Publishing Company, we are in possession of proper facilities for printing. The Miehle presses, which will do our work, are new and of the most improved type. We will only be handicapped (for a few issues) by scarcity of paper; the rush of work at the local photo-engraving houses will prevent the use of half-tones with our reading matter, but we have arrangements pending to have this work done at Sacramento, which city was not affected by the earthquake.

We would urge all of our advertisers whose places of business have suffered, to communicate with us at the earliest moment, as our issue of April 28th will afford the best medium for advising their clients the world over of any change of address.

EDGAR RICKARD,
Business Manager.

sary ammunition. Among my books was a compilation of most of the magazine articles that were published on the Mount Pelée catastrophe of 1902, a subject in which I had been keenly interested because it had been accurately described in the light of modern ideas of vulcanism. By the time Edgar Rickard arrived, I had written an article suitable for our next issue, the publication of which seemed just then most remote.

Edgar brought news. He had walked from the mole to Oakland and then through that town toward Berkeley; on the way he had been fortunate enough to meet Mrs. Charles Butters in her motor-car and had obtained a lift. It appeared that in Oakland the

earthquake had done much damage, all business was at a standstill, wild rumors were afloat that Los Angeles had been overwhelmed by a tidal wave, that Santa Rosa and San José were in ruins, that Denver had been destroyed, that Chicago was under Lake Michigan, and that the railroad system connecting San Francisco with the rest of the country was shattered.

Meanwhile the great mass of smoke across the Bay rose higher and higher into the serene sky until it reached 10,000 ft. vertically, for not a breath of air was felt and the peaceful beauty of nature seemed to deride the welter of destruction into which we had been plunged. Psychologically this was the most vivid moment; we did not know whether or not our local disaster was on the fringe of a cosmic catastrophe; it looked like the end of all things; we were prepared to hear that the rest of the American continent was in the throes of a worldwide horror, and we scarcely dared to ask whether any news had come from Europe. But we possessed an invincible optimism, coupled with a keen appreciation of the capacity for exaggeration possessed by our local newspapers, and so refused to believe the weird tales that had a brief vogue amid an anxious community.

We had work to do; that was the best anodyne. One of the first things Edgar told me was that the mailing list was saved. My readers will know that this is a printed list giving the name of every subscriber, with the address and the date at which each subscription expires. We had only taken control of the M. & S. P. four months earlier, Edgar having become business manager on December 1, 1905, while I assumed the editorship on January 1, 1906; but it was our custom, as it was that of our predecessor, J. F. Halloran, to take home a copy of the mailing list as a safeguard against a fire in the city. Edgar had just returned from a visit to New York, and in his absence I had adopted the same precaution. Thus I had the mailing list for the week ending on April 14, and he had the list for the current week—brought home the evening previous. The point is worth explaining, for it was vital. I turned to him and said: "Well, if the rest of creation is not wiped out, we are all right; we want an office and a printing press; the rest we can manage, for the Lord knows there is news enough." Just then Miss Lie, the typist, arrived and confirmed the destruction of our offices. She had crossed on an early ferry, before communication was cut off, and had been able to go up Market street far enough to see that our building was doomed. We could not telephone to Mr. Young but we were soon in touch with Mr. Dexter. Thereupon Edgar and I went down town, that is, to the business portion of Berkeley, in search of offices and printers. Fortunately a six-story building had just been erected by the First National Bank, and being a steel structure and thoroughly well built, it had survived the earthquake intact; only a little plaster had been shaken loose. Being a new building there were many rooms vacant, and we hastened to take a lease of five on the top floor. Of the two Berkeley newspapers, the *Reporter* had presses large enough for the M. & S. P., which, it must be remembered, was then printed on a 32 by 46 in. sheet, the pages being 11 by 15 inches. It was not until the July following that we reduced the pages to their present size. An arrangement was made with the manager of the *Reporter*; no terms were specified, but he promised "to take care of us." He did! Thus Edgar, as business manager, had leased offices before 3 o'clock and had secured printing facilities before 5 o'clock on the first day of the fire. We bought temporary furniture, mainly kitchen tables, and engaged a number of refugee girls to address envelopes. Already a headquarters for refugees had been opened at Berkeley to take care of the crowds fleeing from the city across the Bay. We realized that the postal service would be so glutted as to prevent acceptance of second-class mail and arranged to send our emergency sheet by letter postage. Foreseeing a rush, Edgar bought the entire stock of stamped envelopes for sale at the Berkeley post-office.

Returning home I found that our neighbors, Mr. and Mrs. William E. Colby, knowing that our chimneys were down, had invited us to dine with them. We dressed as usual and found a party of a dozen people, including the veteran geologist, G. K. Gilbert. As the twilight darkened the flames across the Bay became vivid, and we stood in the window discussing a disaster the full extent of which was still unknown. Our host was a lawyer with an office in the Mills building, on Montgomery street, San Francisco, and as yet the fire had not reached that quarter, although the worst was feared. Those who lived in the city or had crossed early in the morning had been able to reach their offices before the fire spread, but it had availed them little, for in most cases they had failed to foresee the extent of the impending conflagration and had deemed it enough to place their papers in safes that proved useless as a protection against the fierce fire raging on the two subsequent days.

Soon after we had taken our seats at the dinner table, at 7:15 a severe shock was felt and my wife was on the point of hastening to our children next door; but the tremor was brief and we had become accustomed to such happenings, so that the dinner passed pleasantly. It was the last quiet evening most of us enjoyed for many weeks, for during the succeeding days the destruction of the business portion of San Francisco threw the community on its beam ends and created manifold anxieties. As we left our kind hosts and walked the short distance home, Mr. Gilbert was with us, and when we stopped to comment upon the spreading of the fire across the water, he said: "Do you feel as if you had been fiddling," the reference being to Nero's performance while Rome was burning. I answered unhesitatingly: "No, there was nothing we could do, this is a brief interval before days of consuming anxiety, and the quiet evening spent among friends has done good to all of us." He acquiesced. We knew not what was ahead, but we did know that there was lots of work to do.

Next day dawned beautifully. People talked afterward of earthquake weather: it is a fallacy. The day on which the earthquake happened and those that followed were worthy of the best that California gives to her children: without a cloud, without a breeze, not hot, but serene and calm, as if Nature

were lulled in a siesta; it was a glaring contrast to the calamitous event that culminated in the destruction of a beautiful city and the paralysis of a highly organized community. From the Golden Gate San Francisco lifted an ashen face to the blue of a pitilessly perfect sky.

Ready to Begin Again.

By the next day the rumors of general disaster had been contradicted, we learned that the tidal wave at Los Angeles was a myth; the destruction of a large part of Santa Rosa and San José was confirmed but the loss of life was small, Denver and Chicago were still on the map, the railroad was in operation and was taking thousands of refugees from the stricken city. From there the news was worse; the fire was spreading, the water pipes were broken, the gas escaping from mains had been ignited by short-circuiting electric wires. San Francisco was doomed. All the lower part of the town was already gutted by the flames; the Palace Hotel was gone, the St. Francis was threatened, and the Fire Department was helpless, for the chief of the department had been killed during the earthquake. Modern man, in the midst of the complex civilization he had himself created, was more helpless than a savage in a primeval forest.

The earthquake was on Wednesday; on Thursday our staff began to foregather. All were on hand except Mr. Young, from whom we had received no word. On the preceding afternoon D'Arcy Weatherbe, who was then on the editorial staff, had found his way into the city and gathered notes for the vivid article published in our issue of the 28th. On Saturday Weatherbe and Edgar obtained permits, penetrated into the smouldering ruins, and eventually found Mr. Young, whose house was badly shaken but had just escaped the conflagration. As soon as he had seen to the safety and temporary housing of his family, he came to Berkeley and stayed at my house, for we were all keen to rehabilitate the M. & S. P. On the very day of the 'quake Edgar had telegraphed to our agents informing them that we had secured quarters and printing facilities at Berkeley, and instructing them to procure new plates or 'blocks' from our advertisers. I wired to our regular correspondents telling them to send their letters as usual, and at the same time I had sent telegrams to those whose articles were in the issue of April 21, which was going to press on April 18, and was therefore destroyed. I asked the contributors to that issue to send me copies of their articles. In consequence of these steps we had plenty of good material for the issues of April 28 and May 5. In place of the number for April 21 we printed a single sheet—our 'disaster' issue, as we now call it. A facsimile of it appears on another page. The copy was prepared on Thursday, April 19, and went to press in the evening of that day, so that the issue of the M. & S. P. for April 21 appeared at 5 o'clock on April 20, and was promptly mailed in stamped envelopes that had been addressed by refugee girls who were paid by orders on the grocers. Thus the M. & S. P. appeared before the San Francisco fire had stopped spreading. The subsequent issue, that of April 28, was full of interesting accounts of the earthquake, well illustrated, and with plenty of advertising matter.

Opening a Safe in the Ruins.

We did not lose everything in our San Francisco office. Early on the morning of the earthquake John J. Young, the chief of the composing room, and

Philip F. Sage, a clerk, had gone to the top of the six-story building, already racked by the tremors and further endangered by the rapidly encroaching conflagration. Fourteen times did they go up and down the uncertain stairway. Fortunately another tenant in the building, Charles E. Townsend, a patent lawyer, had procured a light wagon from a personal friend, with the purpose of saving his library. An arrangement was promptly made whereby Young and Sage were to help him in moving his books and records, while he would give them the use of the vehicle for transferring such papers and material as they could save from our offices. It was impossible to hire any conveyance at this time. After two hours of hard work the wagon-loads of stuff were taken to the Central market, in the basement of which it was stored. But this building was soon threatened by the advancing fire; Townsend secured another vehicle and hurriedly moved his own belongings, and ours also, to a safer place. To make a long story short, he had to make six hasty removals, losing a few things each time, until finally he buried the lot in a hole dug in a vacant bit of ground near the Hollischikie Club, the members of which helped him to store everything under a safe cover of sand, together with the pictures and other articles of value belonging to the club. There it remained until the fire had spent itself. We supposed everything was lost, but on Friday (April 20) we received a telephone message from Miss Strong, the daughter of Mr. Townsend's business associate, telling us that some of our papers were saved, and on Saturday we heard from Young how it was done. A week later the salvage was disinterred and brought to Berkeley. Among the things that were saved we found the bulk of the contents of the editor's desk, the business manager's 'follow-up file', correspondence covering the last six weeks, an almost complete set of advertising contracts, and the monthly statements ready to be posted to advertisers.

On the ruins of the building that was formerly 330 Market street we found our safe, with a big hole in the side; evidently the iron sheathing had been punctured in falling and the cement lining was mere rubble. As soon as it was cool the safe was hauled to the water-front, where a stream of water was turned into the hole so that the cinders were washed out. These were panned in miner fashion and in the concentrate was found $55 in coin and a medal. This last had been awarded to the M. & S. P. at the Chicago Exposition; it was in an aluminum case, of which the plush covering was now represented by soot, but the aluminum had protected the bronze medal itself so that it was but slightly oxidized. I am glad to say that the gold medal won by the paper at the St. Louis Exposition was saved, for I had given it to Mr. Halloran at the time he resigned control. Of course, all the paper currency and account books in the safe had vanished in smoke.

For ten weeks, until a new addressing machine arrived from Chicago, all the copies of the paper were addressed by hand. Prompt notification to the postmaster at San Francisco caused our mail to be redirected to Berkeley and on the Monday following the earthquake we began to receive letters. This also meant a resumption of revenue, so much needed at a time when the banks were closed, and postal orders served as efficient currency. While the banks of California were officially closed for a couple of months, we had no trouble in arranging for financial credit, at first, and for ordinary exchange, later. Our stock of paper with Blake, Moffitt & Towne was consumed in the fire, but this old firm showed plenty of enterprise and we were soon supplied with excellent paper, furnished to us without extra charge. This was one of the few examples of fair dealing and of a refusal to take advantage of the disaster that had befallen the community. Our other experiences were less pleasant. The manager of the *Reporter* made us pay three times the usual rate for printing and then, assuming that we were helpless, he charged extras until the imposition became intolerable. The presses were in demand for the regular evening edition of the newspaper and a heavy demand for job printing at high rates offered lucrative returns. Moreover, the management of the *Reporter* was in a chaotic condition most of the time, owing to divided control; thus it can be understood that we had to suffer frequent delays and hindrances of an acute kind. The situation was precarious, and we did not know from week to week whether the M. & S. P. would appear or not. Just in the nick of time a printing establishment—that of the Stanley-Taylor Co.—was opened in San Francisco, so we bought a motor-car and sent our 'forms' across the Bay, a distance of 12 miles of land and water. This entailed delays, of course, but it enabled us to escape from the *Reporter*. After the earthquake our composition was done at the printer's but by the end of June our plant, ordered from Philadelphia, arrived; we equipped a composing room of our own in a building on Addison street, and despite the lack of 'sorts' we managed to do pretty well. In April of the following year we moved to San Francisco, and the general offices were once more under the same roof as the composing room, at 667 Howard street. In January, 1908, we installed a Mergenthaler linotype outfit and ceased setting type by hand, except for display advertising.

But I have gone ahead. In preparing for our issue of April 28, which was the first regular issue after the disaster, we reproduced 8 pages of advertisements by zinc-etching from our issue of April 14, and a number of illustrations were made from photographs showing the fire and the effects of the earthquake. This work was done at Oakland, Sacramento, Fresno, and Los Angeles. In order to have good half-tones I sent a number of photographic prints to Chicago. Another sample of unrestrained commercialism was afforded by the Oakland *Tribune*, which charged us five times the usual rate for a few zinc plates that we needed in a hurry for the issue of April 28. Our experiences were like those of others, we saw how small men can be when greedy to make money, but we also had plenty of opportunity to note the enlightened unselfishness of the better element in the community. The refugees from San Francisco know what that means, for the whole of America was so stirred by horror and sympathy as to elicit an astonishing expression of good-will in the form of supplies of food and clothing, accompanied by the most generous out-

Earthquake Rift in Made Ground, East Street Near the Water Front.

The New San Francisco, Palace Hotel, Monadnock, and Call Buildings.

pouring of friendly interest. As I have said, for a time we saw human nature with the clothes off. For two or three weeks the community, with rare exceptions such as I have noted, acted and spoke as if they had the fear of God in their hearts. As normal conditions supervened, they reverted to their old ways, but while the effect lasted it was strong and intensely stimulating.

At that time the congestion of traffic on the railroads was tremendous, for the main lines were glutted with supplies for the refugees, and with every kind of material required by a community temporarily beggared. On the side-tracks at Oakland and Sacramento were thousands of cars consigned to people that had no warehouses and therefore postponed unloading as long as possible. At one time 14,000 cars stood on the tracks. Owing to lack of system, the confusion became so great that cars were lost; it took months to trace a consignment and receive material urgently needed. We suffered by the late delivery of paper, especially the 'cadet blue' cover-paper intended to mark the reduced size of the M. & S. P. from July onward. The issue of July 7 appeared in white, for the cover-paper, ordered four months previous and actually in California before the disaster in April, was not delivered until July, having been returned with 'empties' to Galveston, Texas.

Of course, we worked to all hours, especially Mr. Young, who made himself ill with overwork and devotion to duty. For five or six weeks we knew no intermission, no Sundays, no abatement of the high pressure, but finally one morning I realized that we were "out of the woods", for I picked up my racket and went off at noon to the Country Club to play tennis. That marked the end of the crisis. And when the crisis was over we celebrated our deliverance in the good Anglo-Celtic way: by having a dinner. At that dinner the toast was: "It's the men behind the pulp that make the press."

The earthquake itself was almost forgotten in the devastating fire and the commercial upheaval that ensued. But the scientific aspect of the event has not been overlooked; never was an earthquake so diligently investigated or so thoroughly described. The report issued by the State Earthquake Commission, under the direction of A. C. Lawson, G. K. Gilbert, A. O. Leuschner, and other scientific authorities, was finally published by aid of the Carnegie Institution.

Briefly, the main facts may be stated as follows: The rupture in the earth's crust that was the immediate cause of the seismic phenomena has been traced from Point Delgada to San Juan, a distance of 270 miles. It follows an old line of dislocation and does not conform to the present topography. The plane of rupture is vertical; the vertical displacement was as much as 3 ft. and the horizontal displacement was as much as 21 ft., with an average of fully 10 ft. The zone of destructive effects reached for 35 miles on each side of the fault. Nearness to the fault determined the intensity of the earthquake shocks, but the character of the foundation was also a larger factor in modifying the effect on buildings. Alluvial tracts and filled ground were much more severely shaken than the solid rock. The maximum effects were felt near Bolinas and Inverness. On the Shafter ranch the fault-crevasse entombed a cow, the earthquake-rift marked by a natural trench 6 to 8 ft. wide.

It is recorded that rumbling, as of a train or rushing wind, preceded the big shock. Visible undulations, more than a foot high, were seen on the surface of the ground. Persons were made dizzy and nauseated. Horse and cattle showed fear just before the earthquake and many of them were thrown by the commotion of the ground. Horses whinnied and cattle bellowed in fear, but the noises made by human beings were more varied and more sustained. The shock was perceptible from Coos Bay, in Oregon, to Los Angeles, in California, a distance of 730 miles; laterally the vibrations were felt as far as Winnemucca, Nevada, a distance of 300 miles. This indicates the limits to which the vibrations were sharp enough to appeal to the senses, but the earth-waves pulsated round the entire globe and were recorded by the seismograph in every civilized country. The financial reverberations are felt even to this day. The total loss of life in California was about 1000; the loss of property in San Francisco is estimated at $500,000,000. But the city by the Golden Gate, "the warder of two continents," true to the prophetic words of Bret Harte, rose, "serene, indifferent of fate," from her ruins, imperturbably victorious over Nature and instantly responsive to the energy of her citizens. San Francisco survived; the Mining and Scientific Press survived. It was a great episode.

FARROBAMBA COPPER PROPERTY

This property is situated some 60 miles east of Cuzco, Peru, which is the terminus of a railroad line from Molendo. A report was made on the property for English clients by Gordon Firebrace, and the statements made in this report are absolutely stupendous. The holdings of this group of claims consist of six different properties, only two or three of which have been reported on by Mr. Firebrace. He states in his reports that the principal one of these is the Farrobamba on which there is an outcrop of 1000 metres long, 300 metres wide, and 100 metres high which apparently is solid ore. Shots put in various parts of the outcrop give an average of 8%, which assays from 2 to over 20%, the ore being sulphide. In a supplementary statement which he made for the chairman of the company, he states that there are about 400,000,000 tons of 8% ore. In addition to the vast quantities of ore, it is stated that there are about 125,000 hp. available in the river which flows through the property. On the strength of Mr. Firebrace's report, the company has appropriated £25,000 for carrying on a campaign of development by means of open-cut and churn-drills. They have purchased a Keystone drill in this country which is about to be shipped to Peru and they are engaging a drill runner. In addition they have employed a man who was formerly in charge of the open-cuts on the Dunderline iron mines in Norway. Claude Vautin is now on the way to the property to investigate metallurgical conditions.

Copper Through Fifty Years

Written for the Mining and Scientific Press
By James Douglas

The copper industry of this country since the middle of the last century presents many points of interest. It has been subject to the usual vicissitudes of trade and finance. It has tried the experiment of high protection and of no protection at all. It was at one time controlled by an agreement of the large producers, but during the longer period has been subjected to unlimited and untrameled competition. And yet it has prospered. In production we have grown from almost the most insignificant among the world's contributors to being the controlling influence of the world's market. For our report of our monthly output the copper market waits with bated breath.

In 1850 the rank of the world's copper producing countries was as follows:

WORLD'S PRODUCTION OF COPPER FOR 1850.

Country.	Pounds.	Per cent of total.
Great Britain	29,648,000	26.8
Chile	25,000,000	22.9
Russia	12,900,000	11.8
Austrian Empire	6,660,000	6.0
Cuba	6,800,000	6.3
Australia and New Zealand	7,000,000	6.4
Scandinavia	4,000,000	3.7
German States	2,800,000	2.6
Rest of Europe	2,000,000	1.8
Turkey	2,000,000	1.8
Asia	6,000,000	5.4
South America (except Chile)	2,400,000	2.2
Africa	1,200,000	1.1
United States and Canada	1,300,000	1.2
Total	109,708,000	100.0

In 1909 the position of most of those mentioned above is strangely reversed:

WORLD'S PRODUCTION OF COPPER FOR 1909.

Country.	Pounds.	Per cent of total.
Algeria	224,000	0.01
Argentina	1,120,000	0.06
Australasia	98,560,000	5.22
Austria	2,800,000	0.14
Bolivia	6,160,000	0.32
Canada	51,520,000	2.72
Cape Colony	15,680,000	0.83
Chile	84,000,000	4.54
Great Britain	1,120,000	0.06
Germany	44,800,000	2.37
Hungary	224,000	0.01
Italy	7,840,000	0.41
Japan	115,280,000	5.56
Mexico	125,440,000	6.64
Newfoundland	4,480,000	0.23
Norway	22,400,000	1.18
Peru	44,800,000	2.37
Russia	50,400,000	2.66
Sweden	3,360,000	0.17
Spain and Portugal	116,480,000	6.16
Turkey	2,240,000	0.11
United States	1,099,840,000	58.23
Total	1,888,768,000	100.00

The United States stands first with a production of 1,099,840,000 lb., or 58.23% of the world's production, and Great Britain's production has become a negligible quantity. Spain does not appear in the old list, but today takes second rank. Australia has risen to third place, followed by Chile, which during the seventh decade of the last century rose to first place. Chile then declined through the exhaustion of rich mines, but is again coming to the front. During that period Venezuela became prominent, mainly through one great mine, the New Quebrada, but another has never been found, and the country has disappeared from the list. Peru, on the other hand, is in the ascendant. Africa's contribution during the half century has been from the coast mines of the Cape Copper Co., but may, now that the interior is being reached by rail, become a large factor. The rise or decline of a country's production, or even of a single large mine, may sensibly affect prices, as the volume of the world's copper production is comparatively small. This has been conspicuously shown by our own experience.

From 1857 to 1861, during which year our mines increased their output from 10,700,000 lb. a year to 16,800,000, copper was on the free list and the world's price virtually regulated ours. With the breaking out of the war the Morrill tariff act was passed, which taxed everything on which revenue could be raised, and copper was stricken from the free list. The duty first imposed was 2c. per pound, and from 1864 to 1869 2½c. was the rate. Our production increased from 16,800,000 lb. in 1861 to 28,000,000 in 1869. This rapid rise was due to the development of the Calumet & Hecla. The effect of the 2 and 2½c. duty was immediately felt in the higher price of copper here. In 1863 the price of Lake ingot in this country was 4c. above the price of Chile bars in England. Though this difference was not maintained, the average for a time was about 3 cents.

The tariff tendency—steadily upward till checked—was of course taken advantage of by the copper industries, and therefore they demanded more. The demand was acceded to and the duty on ingots was raised to 5c. in December 1869. And at 5c. per pound it continued till 1882, except during 1872 and 1873, when it was reduced to 4½c. Meanwhile the annual production of the country had risen from 28,000,000 to 90,600,000 lb., and great changes had occurred, disturbing the balance of powers as it existed during the supremacy of the Lake mines. From the time when Calumet & Hecla commenced its phenomenal production, say in 1868, till 1881, the percentage of production by Michigan had never fallen below 80% of the country's total, and had risen as high as 95.7 in 1872. During that period our production had begun to exceed our consumption. There was even a small balance of 102,821 lb. for export in 1864. In order to secure full advantage of the duty under these circumstances some combination by the copper companies had to be devised. The producers outside of Michigan up to that date might be neglected. The Lake companies alone were therefore included in the several plans which were either proposed or carried out. The Mining and Scientific Press, in its issue of July 20, 1872, said: "The copper ring has contracted at a stipulated price for the product of the prominent Lake Su-

perior mines for a certain length of time, reported all the way from six to twelve months." The scheme miscarried, for English holders of Lake copper who had bought large quantities of the metal the previous year, took advantage of the higher American price to unload their unused stock on the market, though the original buyers had pledged themselves not to re-export. The final attempt to create a copper trust commenced in 1879 and ended by decree of the Court in 1885. The story is told in the 'Tariff Reform' Pamphlet Vol. III, No. 2, page 440.

"The combination was formed by the following mines: The Calumet & Hecla, Atlantic, Quincy, Central, Allouez, Franklin, Pewabic, and Huron; the Copper Falls and Conglomerate companies were admitted later. It was agreed that all the sales of copper should be made by the sales agent of the Calumet & Hecla. The aim was to keep up the price of copper in this country to the limit allowed by the tariff of 5c. per pound. The surplus produced over the consumption in the United States was to be exported and sold on the condition that the buyers would not re-import it. This plan continued till 1883, when the sales agent of the Calumet & Hecla died. Thereupon, written contracts were made by all the mines mentioned above, providing that all the copper produced should be pooled and sold by the Calumet & Hecla either in this country or abroad. Ten per cent of the receipts from the sales of copper was to be retained for use either to buy Lake copper in the markets when they should become glutted, or in case it was thought best to hold the copper for a considerable length to assist the weaker mines to continue their operations. This contract was drawn October 13, 1883, to continue in force one year. On February 14, 1884, new contracts were made to continue the arrangements till January 1, 1885, and the third and last contract was drawn up and signed August 20, 1884, to continue the pool one year longer, from January 1, 1885. These contracts gave the Calumet & Hecla complete control over all the copper produced in Michigan to sell when it pleased and at what price it pleased. In the last contract the following provision occurs: 'It is the purpose of the Calumet & Hecla Mining Co. to make a large sale of copper for export at the best price obtainable, from 12,000 to 17,000 tons.' The sale was made and the copper was to be delivered in three installments in November, December, and January, and the price agreed upon was an advance of £4 per ton (equal to 0.86c. per pound) above the average price of Chile bars for those months. The Quincy company objected to this and proceeded to sell its copper for export through certain brokers in New York, who succeeded in getting more than a cent per pound above the price obtained by the Calumet & Hecla.

"The Calumet & Hecla, for itself and the other mines in the pool, applied for an injunction from the Supreme Court of New York, to stop the independent sale of copper by the Quincy company. The Sixth article of the complaint is as follows: 'Acting upon the faith of and in full compliance with said agreements, said Calumet & Hecla Mining Co. entered into an agreement and made a contract with certain European parties for the sale and delivery during the periods covered by said agreements of many thousand tons of copper. A part of the consideration of said last named contract with said European parties was the agreement made by the said Calumet & Hecla Mining Co., acting for itself and for all the other companies above named, that no more copper should be sold by said companies for exportation during said period, and the European parties agreed on their part that none of said copper should be reimported into the United States.' In answer, the defendant, the Quincy Mining Co., declares: 'For an answer and defense herein the defendant alleges that the contracts referred to in the plaintiff's complaint were executed by the several parties thereto for the purpose of carrying into effect agreements which they had made to combine with each other to prevent a free competition among themselves in the business of selling their productions of copper, and to enable the plaintiff, the Calumet & Hecla Mining Co., to control the amount of Lake Superior copper which should be put upon the market, and also to control and to keep up beyond what it would otherwise be, the price at which the same should be sold during the continuance of said contracts.' In January 1885, Judge Lawrence rendered his decision, refusing to grant the injunction on the ground that it was contrary to public policy."

Thus ended the only copper combine made by all the large copper companies who were in active operation at the time of its original formation. But in the interval between 1880 and 1885 natural forces less easy to evade than legal statutes came into play. Arizona had entered the field as a large producer in 1881, and Montana had followed suit in 1882, and these Western companies contained elements more difficult to harmonize than had been found in the little group of Michigan mining companies. The effect on production and on price was startling.

Year.	Production, lb.	Per cent of Increase over previous year	U. S. price of Lake Superior Ingots, cents	Foreign price of Chile bars—2c. under price of Ingots, cents
1881	71,681,000	18.6	18⅛	13¼
1882	90,646,000	12.5	18½	14½
1883	115,526,000	27.4	15⅞	13¾
1884	144,946,000	25.5	13⅞	11⅞
1885	165,875,000	14.4	11⅛	9½
1886	156,735,000	5.5*	11	8¾

*Decrease.

The Lake combination was ineffective in sustaining prices beyond 1882, owing to the entrance of the production of these Western mines into the market of the world and the impossibility of incorporating them into any copper trust. The Arizona Copper Co., making bars which ranked as Chile bars and were worth about 2c. per pound under Lake ingot, might have combined with the Lake companies; for in those early days Montana made matte only, and it was all, or nearly all, shipped to Europe for treatment. An equitable agreement between the Michigan and the Western mines would therefore have

been difficult, even if the personal element among the few men who controlled the copper trade had not erected a more unsurmountable barrier against co-operation than difficulties arising from discrepancies in values and divisions of quantities.

Soon after the appearance of the Western copper the law of supply and demand asserted itself. The enormous and rapidly increasing production of Montana, added to the notable but less phenomenal growth of Arizona's output, made the balance for export so large that the scramble for the protection of the home market became furious. As a consequence the duty soon became inoperative so far as the miner was concerned, and the price in this country fell to that of the world plus the cost of importation. This must inevitably happen with any protected article produced in excess of the home demand, unless some artificial method of making the duty effective is devised. The Anaconda output was in fact the principal factor in bringing about the drop in the world's price of copper in 1885, 1886, and 1887, which preceded the formation of the Secretan Syndicate. The fall in price was so grave as to tell on production, which, as the statistics show, fell off 5.5% between 1885 and 1886. The decline in price was such that Lake copper sold languidly at 10c., and the Copper Queen Co. made contracts for its bars at 8c., and at even a trifle under. The tariff gave the distressed industry no help, but M. Secretan came to its assistance, offering to buy the output of the mines for three years at stipulated figures. There was, however, no understanding or concurrent action among the American producers in their dealings with the French Syndicate. Some producers refused to sell, and with each of those who did sell there was an independent negotiation, and all by no means received a uniform price. The price paid was on an average 5c. per pound higher than had ruled for the two previous years. The effect on production is indicated by a rise of 15.4% between 1886 and 1887, and of 25.17 during the following year. On the failure of the syndicate, production was so far arrested that the figures for 1889 showed, for the whole country, an increase of only half a million. But this stagnation was only temporary. The syndicate stocks were rapidly absorbed or disposed of, and in 1890 the price of copper rose to 15c., and production increased 14.5% over that of 1889. But the terrible crisis of 1893 was at hand, and told disastrously on both production and prices.

In 1893 the situation changed. There was a decrease instead of an increase in production, and the average price for Lake ingot fell to 9.5c. Despite the staggering blow the copper trade rapidly picked up courage, and in 1894 showed a 7½% increase over 1893 and a rise in price of 1¼c. This resiliency, when the whole country was prostrate, may have been in spite of or may have been the result of, the self reliance which the placing of copper on the free list by the McKinley bill may have engendered. The plea for punishing the copper companies was that they had conspired with a foreign syndicate to artificially and injuriously influence prices. In fact, the companies which did sell to M. Secretan did individually what has been done before and since, namely, sold their production ahead to the highest bidder, at a most tempting figure, which raised most of the blighted concerns from despair into easy circumstances. So little benefit was derived from the tariff that when the trade was threatened by the complete removal of tariff protection the companies did not send a lobby to Washington or even protest. For years protection had ceased to protect. Every large company had opened its European sales agency and had secured its own customers, and therefore a market had been found for the total American surplus, no matter what it might be, if only the world's price were accepted. The removal of the duty therefore made no difference, but the financial crisis of 1893 did. Yet it was chiefly in the dividends. The price continued low till 1898, when a wave of high price developed, followed in 1902 by another decline. This lasted for three years, when a second wave within a decade of excessive price set in, followed by a relapse.

These serious vascillations in price doubtless create disturbance in trade and stimulate, even if they do not originate, speculative manipulation. The only remedy conceivable would be a vast combination, which would include both the mining and manufacturing interests, wealthy enough to absorb the existing companies by tempting the weak, and so omnipotent that no opposition could be started without risk of being crushed. The Secretan schemes were wrecked by not placating the manufacturers of the world, who unearthed unsuspected stocks of old and new copper of surprising magnitude. This remedy would probably be again administered. But assuming that such a world-wide combination in restraint of trade could be brought about with the view of securing stability of price, two consequences would follow. The price would inevitably be so high that the public would pay very dearly for the luxury of consistent uniformity in value. And as a result of high prices reduction in demand would follow. The supply can be controlled—the demand cannot, unless under rigid public control under State socialism. Past history showed a tariff without a trust to be powerless to create uniformity. A copper trust can no more be framed today than it could in the past. What we need more than a trust at present in this country is a large increase in consumption to use up the surplus that has been created during the past dull period. In this connection there would appear to be a great field for increasing consumption, if our copper mills would see their way clear to roll standard sizes of copper sheets for architectural purposes, and sell them to the public for roofing and such work as cheaply as copper wire is being sold at present. In the copper mills of Europe the difference between the price of wire and copper sheets is very much less than it is in this country, and this matter is well worth the serious consideration of our copper manufacturers, if they desire to retain this branch of their business for any long period.

During the past six years, 7920 wells have been sunk in the United States, and eleven and a half millions of barrels of crude oil produced.—Mining and Scientific Press, September 21, 1867.

An Early Opinion of Alaska

Written for the Mining and Scientific Press
By William P. Blake

You have asked me for a few words about Alaska as I know it in the year 1863. A year or more in Japan gave me many friends among the officers of the Imperial Russian navy. Meeting the commander of the corvette *Rhynda* in Shanghai when I was seeking a vessel for America, he said (with the consent of the Admiral of the station): "Come with me. I am bound for your country by way of our Russian America." I accepted the invitation. Leaving Shanghai we steamed to Hakodate, Japan, and thence by sail, skirting the southern side of the Aleutian Islands and encountering the ice-cold currents from the Arctic seas until we reached the forest-covered shores of Russian America at Sitka. The opening of sealed orders revealed the fact that exploration of the resources of the country was intended. Two boat expeditions were organized, one to proceed up the Stikine river into the interior by whale-boat and the other to study the hydrography of the coast. I was invited to join either one, and at once chose the Stikine boat party as offering me the best chance to learn something of the then unknown land. We were frequently the guests of the Governor General of Russian America, Prince Maxsutoff, at his castle in whose halls I found large slabs of native copper from the 'Copper Mine' river; pieces that reminded me of our mass-copper of Keweenaw, Lake Superior. We heard also of the believed great copper masses of Medni island, one of the Aleutian chain, and the only island I believe reserved from the sale, later, by the Russian Government.

After a few days in Sitka the boat party of picked sailors under the command of Lieut. Pererelesbin was organized, and we started for the interior. We rowed up the stream by day and camped upon the banks by night. The granitic and schistose rocks were in strong contrast with the generally volcanic shores of Japan, and had a familiar welcoming look, reminding me of old friends of my hammer in California. The banks and terraces carried some fine scale-gold, very light and evidently washed from far away sources in the northwest; probably from the Blue mountains of the interior. The first and most important discovery was that the upper parts of the Stikine followed a long interior valley parallel with the coast; its lower reaches cutting across what may be termed the coast ranges by a series of gorges and canyons. We had been told of 'mountains of ice' and soon found them to be glaciers of great extent, some of them with old terminal moraines crowding the river out of its course. Some were disgorged from hanging valleys. One I named the Popoff, in honor of Admiral Popoff.

Our progress up the rapidly flowing stream was slow, and for part of the way we resorted to towing by means of a long line from the boat to the shore. The ice of the headwaters of the Stikine was breaking up and huge cakes were floating down. The buds of the deciduous trees along the shores were bursting and the drumming of the grouse in the forest was a familiar sound as we passed under the shadow of the cliffs. A few hardy miners who had survived the terrors of an almost arctic winter were met on their way down the river to the coast with their hoards of gold, wrested by hard labor from the placers, and fortunate enough to escape death by freezing. From these miners I learned many interesting details of the low and high placers of the Blue mountains of the main range. It was evident that the ranges were gold-bearing, and from the general topography it was fair to conclude that the goldfields were co-extensive with the elevation and prolongation of the gold-bearing rocks.

I was not then aware of the negotiations for the purchase of Russian America, if indeed the negotiations had begun so early, but when I reached Washington in 1868, returning from the Paris Exposition of 1867, the advisability of acquiring the region was under active discussion in Congress. Some thought it would be a foolish waste of money to buy such an utterly worthless wilderness—a region of ice, snow, and savages. W. H. Seward, Secretary of State, was urging the appropriation for the purchase, and hearing that I had been in that region requested an evening at his home to learn what I thought of it. At the close of this interview he asked me to give him the substance of my opinion of the country in writing, which was done. He sent it to President Grant, who at once made it a special message to Congress, and it was so published.* In that statement, opinion, or report (the first and only one at that time), attention was directed not alone to the value of the country for gold, but for copper. The opinion was expressed that the goldfields would be found to extend to the very shores of the icy sea, the full length of the country. Attention was also directed to the resources of the region for timber, for fisheries, and for furs. Some of my professional brethren may say that the gold I wrote of was not 'in sight', which is true enough, but the case did not permit of blocking out the ground and weighing the metal. Years must elapse before that can be done, but I submit that my opinion of Alaska has been amply justified.

Fuel required to thaw gravel may be estimated on the following assumptions: That a cubic yard of gravel in place contains 3000 lb. of solids with a coefficient of thermal capacity of 0.2, and 387.5 lb. of ice with an average coefficient of thermal capacity of 0.75; that the temperature is raised 50° F.; that a pound of coal contains 13,000 B. T. U.; that the boiler efficiency is 50%; that 75% of the heat leaving the boiler is absorbed by the ground. Then heat absorbed per pound of coal equals 4875 B. T. U.; heat required to raise 3000 lb. gravel 50° equals 30,000 B. T. U.; heat required to raise 3875 lb. ice 50° equals 14,531 B. T. U.; total heat required per yard of gravel equals 44,531 B. T. U. Pounds of coal per yard, 9.1345; cubic yards gravel per ton of coal, 218.8. Then, roughly, 8 tons of coal per foot of depth per acre are required to thaw the gravel. Roughly, the fuel required to thaw 'muck' is as 3 is to 2 compared with gravel; thus, 12 tons of coal are needed per foot deep of 'muck' per acre.

* House Ex. Doc. 40 Cong. 2 Sess. No. 177. Pt. ii. 1868.

Fifty Years of Advertising

Written for the MINING AND SCIENTIFIC PRESS
By L. A. GREENE

Advertising for the past fifty years has made large progress. A perusal of the columns of the MINING AND SCIENTIFIC PRESS in the sixties emphasizes this fact most forcibly. In those days the advertiser was entirely satisfied to announce in stilted form his place of business and what he offered for sale. No particular arguments were advanced as to why the reader should buy, nor were the merits of the product discussed. Illustrations were used in very few cases, but a new advertisement was the signal for the immediate publication on the first page of an extended description of the machine or device offered for sale, written in superlative terms and assuring the reader that the editor had never before known of quite so marvelous a contrivance. The editorial and business departments collaborated in those days, while now they are entirely separate, and the stern editor allows the business manager to speak only on special occasions.

The 'Scientific Press' of 1860 contained advertisements of all kinds. At its inception the paper was not devoted exclusively to mining, and the hardware store, the dentist, the patent medicine man, even 'drinking emporiums' carried cards in its columns. Dancing schools, the opera, sewing machines, hay presses, a patent mono-rail street car, an egg substitute, pain killers, monuments, clothing stores, Dan Rice's circus, undertakers, washing machines, even the Siamese Twins, were duly advertised. This class of advertising soon disappeared. The patent medicine gave way to the ore crusher, and the 'Household Hints' to the technical article, and within a year the paper developed into a journal particularly devoted to metal mining. Its advertising pages grew in number and improved in character. The advertiser began to advance reasons for buying his goods, and illustrations appeared. The era of specialization developed the trade paper, each industry having its own journals and offering through their advertising pages a medium to reach that particular trade. A maximum of efficient circulation was thus secured to manufacturers and dealers in each line.

Although many of the advertisers of those early days have disappeared, some of them are in business today, enjoying the confidence of the readers of the MINING AND SCIENTIFIC PRESS as they did then.

A Group of Pioneer Mining Machinery Men of San Francisco.

Standing, left to right: 1—Bob Kerr; 2—E. A. Rix; 3—R. B. Noyes; 4—Sam'l J. Hendy; 5 ——; 6—A. J. Kittridge; 7—John J. Hendy.
Seated, left to right: 1 ——; 2—Joshua Hendy; 3—Wm. H. Reynolds.

The oldest regular advertiser in our paper is the Risdon Iron Works of San Francisco. Under the name of Lewis, Coffey & Risdon they first advertised with us June 29, 1861. A most interesting picture of their boiler shop at Bush and Market streets in 1862 appears in their advertisement in today's issue, and it is hard to realize that what was then the location of their plant, is now the busiest part of San Francisco. We find in our issue of July 15, 1865, that Hungerford & Hendy advertised the Prater concentrator as having received a prize at the Mechanics Institute Fair of 1864. The foundation of this company was laid in 1858 by the late Joshua Hendy, who engaged in the sale of saw-mill machinery. Ever since then the name of Hendy has been identified

with the machinery business of the Pacific Coast. After the destruction of their works in the fire of 1906 they established a new plant at Sunnyvale and maintain general offices and salesrooms in San Francisco. Harron, Rickard & McCone succeeded Parke & Lacy, who first advertised in the MINING AND SCIENTIFIC PRESS in 1874. The present firm has advertised continuously since. The Union Iron Works of San Francisco was started in 1849 by James and Peter Donahue. They began advertising in our issue of November 23, 1861. The first iron casting made on the Pacific Coast was turned out by them and cost 50 cents per pound to manufacture. Some of our warships testify to their efficiency, and they are also important factors in the mining machinery business of the West. W. T. Garratt & Co., who are still in business in San Francisco, appeared in our issue of October 7, 1862. The Selby Smelting & Lead Co. have advertised since 1870, and as far back as 1872 we find Francis Smith & Co. and The Gutta Percha & Rubber Mfg. Co. using the PRESS. The San Francisco Plating Works started in business in 1867, and since 1870 they have kept before the readers of our paper. A. Van der Naillen, of Oakland, California, has advertised his 'School of Practical Mining' for 30 years or more.

One well known firm of today that is even older than this paper is A. Leschen & Sons Rope Co. of St. Louis, Missouri. They organized in 1857. Today their plant covers 33 acres devoted to the manufacture of wire rope and aerial wire-rope tramways. St. Louis is also the home of the Broderick & Bascom Rope Co. The economical transportation of ore owes much to these firms. Another prominent figure in the machinery business of the Coast is E. A. Rix of the Rix Compressed Air & Drill Co. of San Francisco. As far back as 1878 the name of Reynolds & Rix appeared in our advertising columns. Today Mr. Rix can give many younger opponents a keen match at golf. The Ingersoll Rock Drill was handled on the Pacific Coast by various agents as far back as 1875, and they advertised it extensively. Louis Falkenau, who now conducts the Falkenau Assaying Co., of Oakland, California, was associated in 1868 with Henry G. Hanks under the name of Pacific Chemical Works. Mr. Hanks was the father of Abbot A. Hanks. The Baldwin Locomotive Works first appeared in our advertising pages in 1871. Fraser, Chalmers & Co. advertised in 1875, and was later one of the companies forming the Allis-Chalmers Company.

Among the earliest dealers in assayers' supplies on the Pacific Coast were Justinian Caire, organized in 1851, and John Taylor & Co., founded in 1852, in San Francisco. The former concern was incorporated in 1895 as the Justinian Caire Co., with Mr. Caire's two sons as managers. An interesting circumstance is the fact that they are today located within half a block of their store of 1880, after various removals due to fire and other causes. John Taylor & Co. was succeeded by F. W. Braun, and in 1908 the firm of Braun-Knecht-Heimann Co. was organized. The Braun Corporation, an affiliated company, has its headquarters at Los Angeles. Gradually Eastern manufacturers began to advertise, realizing the power of a paper published in the territory they desired to reach.

The contrast between the advertisements of fifty years ago and those of today is remarkable. Today emphasis is placed on the possible buyer's needs and the firm's power to serve him. No more do the mighty slogans, 'we lead where others follow', 'we make the best', and 'satisfaction guaranteed', convince the wary. The cautious man is the desirable customer, and one insertion of an advertisement may not interest him, but placing it before him regularly, attractively, and at opportune times will certainly cause him to associate the advertiser's name with the product. The readers of a technical paper should remember that each of these advertisements represents more than the mere illustration and type. They are the result of the hardest kind of work from the time the device advertised is an indefinite idea in the mind of the inventor, through the tedious experimental period, to the time it is presented in a finished and practical form. Think of that when looking through the advertisements, and remember that the manufacturers can only give the most meagre information in their advertisements, but are ready to supply much fuller details should they be required. Trade catalogues and bulletins of machinery firms are splendid productions and full of information, and are published at great expense. They form an excellent reference library. No concern gets so well known that it can stop advertising, for its competitor will surely supplant it. Who remembers the names of the vice-presidential candidates with Bryan? They were well advertised for awhile. But Bryan has an 'until forbid' contract. Today the effective advertisement must talk like a salesman, not repeat itself —and keep everlastingly at it.

MANAGING SALESMEN

The letter printed below illustrates some of the difficulties involved in selling goods through traveling agents. It is a copy of a genuine letter and is published by the courtesy of Charles T. Hutchinson, of the Joshua Hendy Iron Works, though he assures us it was not sent to a machinery salesman. Since the letter is written in English, German, and Yiddish, there are parts which will appeal to all of our readers, especially those who have at times been compelled to make sales whether business was good or not.

Dear Salesman:

On the furst of the month ve wrote you for your expense account, und gestern hat es rein gekomen. Ve cannot make head nur tail mid it. You have used $90.14 and your sales were $16.00. Mitel be you call dat bizness. A salesman is a person vat sells guts und makes for his balbossen sum masumen. You make us mahula and my bartner is balt mashuga in his kopf from dis. When you come hy us, die mispocha hat sur mir gesagen dat you were an actor, a gimbler und a volunteer fireman, but as we do not like a theater mit our guts, you will have to do more bizness mit weniger expenses, otherwise we cannot use you.

Believe us to be still in bizness vitout you.

Mining and Scientific Press in Early Days

Written for the MINING AND SCIENTIFIC PRESS
By ROSSITER W. RAYMOND

The notice of the fiftieth anniversary of the MINING AND SCIENTIFIC PRESS recalls vividly to my mind the early days, in which I first became acquainted with this journal, its work, and its editors. At the age of 28, after some years of technical study in Europe, other years of service in the U. S. Army, and a year of practice as a mining engineer and editor of the *American Journal of Mining* (now *The Engineering and Mining Journal*), I was, in 1868, surprised by an appointment as U. S. Commissioner of Mining Statistics for the States and Territories West of the Rocky Mountains, to succeed Mr. J. Ross Browne, who had been suddenly nominated as minister to China. Mr. Browne was not, and did not profess to be, either a mining engineer or a diplomatist; yet he filled with credit both the positions named, by virtue of his upright personal character and the general knowledge, tact, and insight acquired in a long and varied experience as traveler, author, and journalist. The two volumes of his reports as Commissioner, while they cannot claim to be classics of technical literature, are full of material, the historical value of which he instinctively recognized, and which a more pedantic observer would have overlooked. His son, Mr. Ross E. Browne, has achieved, as a mining engineer, an enviable reputation; but, whatever laurels he may win, he need never be ashamed of the pioneer work of his father.

As I believe, I owed my unexpected appointment as Mr. Browne's successor to the circumstance that certain articles of mine in the *American Journal of Mining* had attracted the attention of the two Senators from Nevada (Stewart and Nye), whose interest in the matter gave them a corresponding influence. Moreover, there was, at the moment, only a small sum remaining from the appropriation available for this work. Under the impression that no new Commissioner would be named until after Congress should have furnished the means for an adequate discharge of his duties, many persons, better qualified than I, had not been brought by their friends to the attention of the Secretary of the Treasury, who held the power of appointment—the office being simply that of a special agent of his department. Indeed, Mr. Hugh McCulloch, then Secretary of the Treasury, was inclined to take the view that it was not worth while to appoint a new Commissioner for the expenditure of so little money; but, after conference with my Senatorial sponsors, and a personal interview with me, he appointed me, upon the understanding that my first report, rendered with such slender financial means, should terminate my service, unless it commanded further Congressional support by legislation.

I recall these circumstances in order to acknowledge the generous assistance to which I was indebted for the success of an undertaking so adventurously and inauspiciously begun. It was after, in the ignorance of innocence, I had accepted a sort of forlorn hope, for which there seemed to be no competitors, that I found how many men were better entitled to the position, and might have accepted it, if the 'hope' had been less 'forlorn'. It would be unkind to name them; but the names of many of them will at once occur to the minds of those who remember the situation of that period. I may say, comprehensively, that I am thinking of men who were residents of the Pacific slope, already familiar with the exploration and exploitation of its mineral resources, and fully entitled by their past services to the recognition involved in a Government appointment. If further particulars should be desired by the curious reader, let him consult my eight reports as U. S. Commissioner of Mining Statistics, published from 1869 to 1876 inclusive, in which I think he will find the names of all these men, as generous contributors.

When I undertook that work, I was hampered, on one hand, by youth, inexperience, and the lack of means, and aided, on the other hand, by the cordial assistance of my old Freiberg colleagues; the correspondents of the journal of which I was the editor; and the men indicated, though not named, above. If I remember correctly, I had, the first year, $5000, and in no succeeding year of the eight during which I served, more than $15,000, to pay all salaries, traveling expenses, and clerical or other labor involved in my work. In any comparison of my reports with the volumes since issued by the United States Government upon economic geology, our mineral resources, our mining and metallurgical industries, this fact should be kept in mind. Yet I am not entitled to personal credit for the remarkable value of the books produced for eight years at so small an annual expense. This credit is due to the co-operation of many who could have commanded large sums for the knowledge and experience which they freely placed at my disposal.

In my annual journeys I encountered, of course, much suspicion and distrust, of the kind which the agents of the Census are still, in lesser degree, liable to meet among ignorant portions of our population. At that time the miners of the Pacific slope had previously settled their own laws and customs, and did not relish Federal intervention. The United States statute of 1866 had not disturbed them much, because it was, in fact, no more than a ratification of their own local system, coupled with an almost unlimited approval of whatever they might choose to enact, not inconsistent with the very liberal features of the Federal statute. But they did not care for further inquiry or further legislation. As I said in my first report, "the present law (the Act of 1866) is not operating at all; therefore the question of its benefits can hardly be answered." In fact, it accomplished little more than to legalize the existing customs of miners.

Gregory Yale, father of Charles G. Yale (long time editor of the MINING AND SCIENTIFIC PRESS) had then recently issued his treatise on 'Mining-Claims and Water-Rights', giving a clear, comprehensive statement of the existing situation, with a synopsis of local mining codes and an intelligent commentary upon the new Federal law. This book, which

Curtis H. Lindley, the most eminent of our publicists in that department,[1] characterizes as "the pioneer work on the subject of American mining law," has remained, ever since its appearance, a historic authority. In my first official report,[2] I acknowledged my indebtedness to this critical, comprehensive, and suggestive summary; and I acknowledge again with gratitude the cordial greeting and effective assistance which I received from Mr. Yale and his associates when, in the course of my peripatetic administration, I first visited San Francisco.

At that time I knew the MINING AND SCIENTIFIC PRESS only as an 'exchange' in the editorial sanctum; but I had recognized it as a technical journal, occupying the double position indicated by its title. In other words, it used to publish, not only really 'scientific' (and therefore disinterested) contributions, but also the statements, questions, criticisms, and crude theories of those who had 'axes to grind', or who were simply disinterestedly ignorant. In my judgment, this was, and still is, to a reasonable extent, the proper function of a popular technical journal, though it does not follow that editorial endorsement should be given to untried or manifestly unfounded propositions.

According to my recollection, the MINING AND SCIENTIFIC PRESS, while giving a hearing in its columns to many speculative, or even visionary propositions, always maintained editorially an attitude in favor of sane scientific methods and conclusions. In this way, I think, it served two great ends, of equal value, namely: the encouragement of suggestions, even from the ignorant, which might contain facts of importance; and the enforcement of the principles of science under which alone such suggestions could be suitably weighed and utilized. The history of technical progress has abundantly proved that the accredited representatives of science (that is, of the summary of facts and laws already generally accepted) cannot afford to despise the observations and experiences of those 'practical' men who are not scientific, because they do not know all that has previously been done by others. Such men should have a hearing. In many instances they have something to say which is worth notice. And a journal which records their (perhaps crude) statements and views is furnishing material for the science of the future. I am more disposed to emphasize and praise this feature of the management of the MINING AND SCIENTIFIC PRESS because I have devoted my life, for nearly forty years, to a technical society, organized upon the same principle. The American Institute of Mining Engineers, organized in 1871, has admitted to membership all respectable persons practically connected with mining, metallurgy, and related work, as well as those who held professional degrees. Its first President was 'Father Thomas', a dear, plain old Welshman, who claimed no 'scientific' standing whatever, but had been a pioneer in the manufacture of pig iron with anthracite fuel. Its membership has included common miners, mine-foremen, and others directly connected with mining or metallurgical work, though not the holders of academic degrees, or entitled to formal professional recognition. And the result of its work on these broad lines has been such as to challenge the criticism and command the admiration of the world. I do not enter here upon any proof of this assertion; for I cite the case merely in confirmation of the proposition that the great success of the MINING AND SCIENTIFIC PRESS is due to its skillful application of the same principle.

I may be permitted to say, however, without disparagement of its early managers, that its editorial force is, at present, more perfectly equipped for technical verdicts, and more disposed to deliver them, than it was fifty years ago. This is undoubtedly an improvement; yet it has had its incidental drawbacks. The new editorial boldness, born of conscious power and confidence, has exhibited itself in some utterances which I could not approve, though I did not question the right of the Editor to utter his conscientious convictions. But this need not prevent me from praising the general independence and high standard of the management.

When, just after T. A. Rickard had secured control of this journal, the earthquake and conflagration which devastated San Francisco overwhelmed his enterprise, with so many others, in apparently hopeless ruin, we were all thrilled with sympathy and admiration to see the MINING AND SCIENTIFIC PRESS emerge from that catastrophe, erect and undismayed; and we all join in congratulations upon its fiftieth anniversary, attended, as it is, with indubitable signs and omens of renewed and increased strength, and a career of continued usefulness and honor.

Nebraska.—A new and probably important mining region has been discovered in the western portion of Nebraska Territory. The discovery was made in September last by a party of some twenty miners, who were returning from the Bitter Root Valley Diggings, to Salt Lake. They collected about $50,000 in a few weeks, which they took to Salt Lake. This newly discovered mining district commences on Wind river, about 400 miles North-west from Fort Loramie, and embraces an area of about 200 miles in length by 100 in breadth. The deposits discovered up to the present time are of gulch gold, very similar in appearance and richness to those of the Feather river mines. It will assay at least $18 to the ounce. The region is the same as that described by Lieut. Reynolds, of the United States Topographical Engineers, in his report of 1859, in which he states that he discovered gold in all the streams embraced within a distance of some 200 miles. It lies at the eastern base of the Rocky Mountains, and is similar in its geological formation to the Salmon river and Bitter Root Valley districts, where rich deposits of gold have been discovered within the past year. The miners who discovered these new diggings unite in the opinion that they will prove fully equal to any ever discovered on the continent. The distance from Omaha to the Wind River Mountains, at the base of which the first discoveries were made, is about 900 miles.—February 9, 1863.

History of the Rock Drill

Written for the MINING AND SCIENTIFIC PRESS
By W. L. SAUNDERS

The percussion rock-drill, as distinguished from other types, is an American invention, the first practical patents having been taken out by J. J. Couch, of Philadelphia, in 1849. He was assisted in building this drill by Joseph W. Fowle, later of Boston, their experiments being carried on during the year 1848. The Couch drill was a crank-and-fly-wheel machine and its application to practical work was, therefore, limited to surface hole drilling. In 1848 Couch and Fowle separated, Mr. Fowle filing a caveat in 1849. This caveat describes the type of successful power rock-drills used today. The chief point was that he first showed a drill where the cutting tool is attached directly to the piston or to the crosshead connected with the piston. In other words, the bit leading into the hole was an extension of the piston rod. This important invention was described by Mr. Fowle in his testimony before the Massachusetts legislative committee in the contest with Burleigh in 1874, as follows: "My first idea of ever driving a rock-drill by direct action came about in this way: I was sitting in my office one day after my business had failed and happening to take up an old steam cylinder, I unconsciously put it in my mouth and blew the rod in and out, using it to drive in some tacks with which a few circulars were fastened to the wall."

The nearest approach to rock-drill inventions abroad was in the German work of Schumann, in 1854. Mr. Fowle being without means, but a genius in the true sense, his inventions remained in obscurity until Charles Burleigh purchased his patents and produced the Burleigh drill, about the year 1866. This drill was used in the Hoosac tunnel in 1867. Following these inventors came Haupt, De Volson Wood, and Simon Ingersoll, followed by Sergeant, Waring, and Githens; Githens being the inventor of the Rand drill. The Ingersoll drill was invented in 1871.

Simon Ingersoll, an ingenious, modest and honest mechanic, came to New York from Connecticut. Having a very fertile mind, he had conceived several inventions, models for which he made with his own hands. Being of a very confiding and loquacious disposition, he once, while riding in a horse-car in New York, described to a fellow-passenger the merits of his invention. One of the passengers in the car who overheard the conversation was John D. Miner, a contractor, who had a gang of men at work upon rock-excavation in what was then the upper part of New York. Mr. Miner broke into the conversation by asking Mr. Ingersoll why he didn't invent a rock-drill, something practical, something useful, instead of spending his time and his genius upon 'such traps'. Ingersoll asked him what he meant by a rock-drill, and what he wanted to do. Miner's reply was that he had a gang of men at work in New York striking steel with a hammer in order to make holes in rock for blasting, that they could only do about 10 ft. per day, and that he could not see why the work should not be done by machinery. Ingersoll said he could make a machine to drill the rock and would go at it at once if he had the money. Miner then and there gave him $50, together with his card, telling Ingersoll that, though he had never met him before, he had an honest face and he would trust him to spend that $50 in building a rock-drill. "When you want any more," said Miner, "come to me and I'll give you another fifty."

Mr. Ingersoll made his drawings and models and built his first rock-drill at a little shop on the corner of Second avenue and Twenty-second street, owned by J. E. de Navarro, who operated it under the management and title of Sergeant & Cullingworth. Henry C. Sergeant came into the works one day and saw the patterns for the drill. The front head was attached to, and was a part of, the cylinder. Mr. Sergeant's fertility in inventions was never more marked than when he promptly told the mechanics that the head and cylinder should be in two pieces; and of his own accord he took a hand-saw and was in the act of separating them when the inventor Ingersoll arrived. "What are you doing?" said Ingersoll. "I'm making this thing practical," was Sergeant's response as he finished sawing off the head before Ingersoll could stop him. The result was the first row between Ingersoll and Sergeant, which afterward resulted in Sergeant's inducing Mr. Navarro to purchase all Ingersoll's rights and patents; but the drill was made with the detached front head, as it is today.

The success of the machine was soon apparent, and after Mr. Navarro had purchased the patents he organized a company called the Ingersoll Rock Drill Co., putting $10,000 in the enterprise. Mr. Sergeant was now in full control and through him many very important improvements were made. Litigation arose at once with Mr. Burleigh of Massachusetts, who owned the Fowle and other rights; but through Mr. Navarro's plentiful command of funds and his liberal nature, the suits were settled and all fundamental patents placed with the Ingersoll company. The $10,000 which started the drill business was shortly afterward paid back to Mr. Navarro, and eventually he sold his rights for $525,000. Mr. Sergeant having sold out because of friction with the management, went West, engaged in mining, lost his money, returned to New York about the year 1885 and started the Sergeant Drill Company.

Addison C. and Jasper R. Rand had early become interested in rock-drills through their connection with the Laflin & Rand Powder Co. Addison C. Rand formed the Rand & Waring Drill & Compressor Co., later controlled entirely by Mr. Rand and merged into the Rand Drill Co., established in 1871 and incorporated in 1879. J. C. Githens, manufacturing superintendent of the Rand Drill Co., was the inventor of the 'Little Giant' rock-drill and also the double-screw column with column arm, which made practical the application of the rock-drill for mining and tunneling. The Sergeant & Cullingworth Co., a manufacturing concern engaged in building the Ingersoll drill, the Sergeant Drill Co., and the Ingersoll Rock Drill Co. were merged into the Ingersoll-Sergeant Drill Co., and later on the Rand Drill Co. was added to this amalgamation, forming the Ingersoll-Rand Co.

The California Stamp-Mill

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB

On the occasion of the golden jubilee, celebrating the fiftieth anniversary of the discovery of gold in California, the MINING AND SCIENTIFIC PRESS published an article by C. P. Stanford giving the origin of the California stamp-mill. He attributes the first improvement that led to the modern type of mill to his conception of providing a round stem, from which followed necessarily a similar shape for shoe, boss-head, and tappet. This mill was on Nathenas creek, in El Dorado county, and the date was 1851. This was by no means the first stamp-mill in the State. Mr. Stanford describes in his article an earlier stamp-mill erected by the Tennessee Quartz Mining Co. on the Cosumnes river, below the Union mine, which latter property belonged to him in conjunction with his brother and others. The original construction followed the model of the stamp-mills long used in the gold-belt of the Southern Appalachian region. He says of it: "The bed for the mortar block and battery frame consisted of layers of timbers crossing at right angles, tamped with sand, and flooded with water. On this was placed the frame of the battery, and between the posts was fitted the mortar block, not standing on end and deep in the ground, but lying on the ground, as did all the timbers under it. On the block was placed a low mortar, and the sides were built up of plank, and carefully secured with rods and bolts and screws. In the mortar stood five stamps, each consisting of a head 18 in. long by 6 in. square, without any shoe, and a timber 10 ft. long by 7 in. square. Through this timber was a slot wide enough to let the cam play freely through it. The upper end of this slot, when the cam stood on the die, was about on a level with the upper side of the cam-shaft, and was the point at which the cam took hold of the stamps to lift it up and drop it, the stamp being kept in place by suitable guides, top and bottom. The cams were much straighter than the tangent cams now used."

Medieval Stamp-Mill, After Agricola.

The troubles encountered are graphically portrayed. The amalgamator is still familiar with 'troubles'; he has so many of them as to think he possesses a virtual monopoly among metallurgists of this sort of thing. But the modern millman is not accustomed to find the boss-head, after a few hours work, worn to the shape of a sled-runner, nor to spend half of each day repairing the damages done to the plant by operating it the other half.

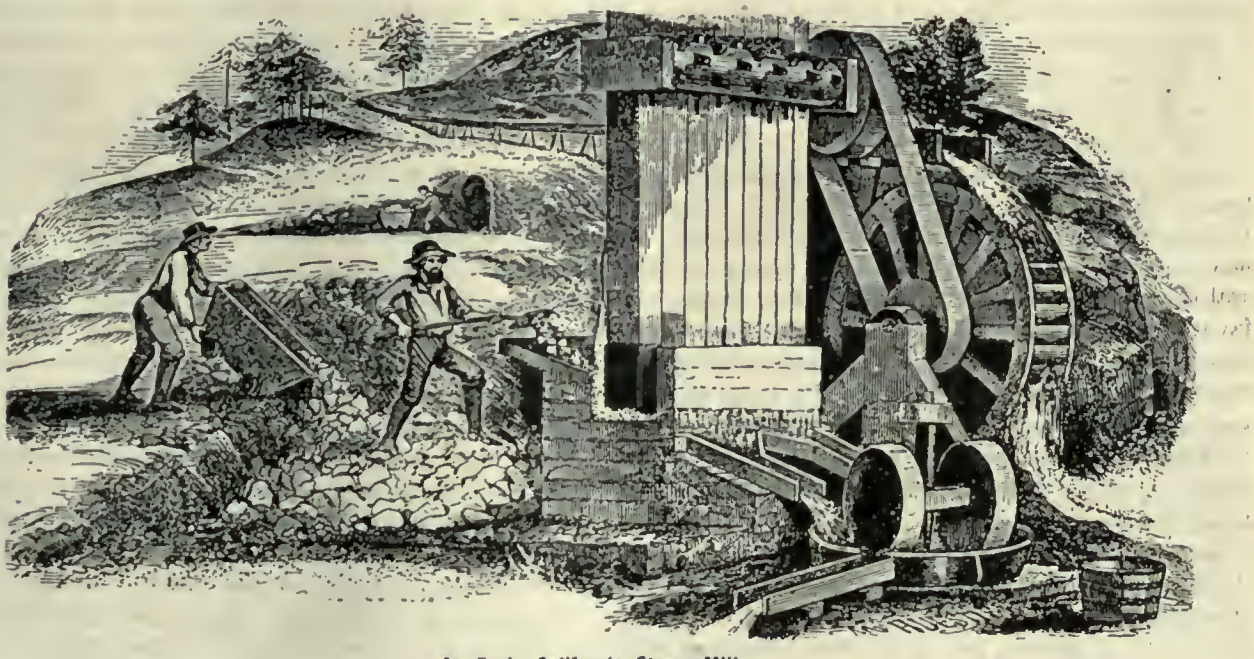
When round stamps were conceived the first trial was made with two pieces of round iron, 2¾ in. diam. by 12 ft. long. The success of these two stamps was so great that a full 5-stamp mortar was erected in February 1852, using shafting 2⅔ in. diam. The stems, however, were prevented from rotating. It was some time before the value of rotation was perceived, and it is interesting to note that the change was made by intention, not by accident. The honor for this is conceded to Isaac Fisk, a plain machinist who was connected with the company in which Mr. Stanford was co-owner. The first attempts were not eminently successful; the corner of the cam raked across the edge of the tappet, and it required considerable ingenuity to work out, in a rule-of-thumb manner, the proper curve for the cam so as to prevent excessive wear. This origin of the revolving stamp in the mill on the Cosumnes river is conceded by others who are in a position to know, among them being Almarin B. Paul, who also contributed an interesting historical article on stamp-milling to the golden jubilee number of the PRESS above mentioned. The gib-tappet, another improvement of immense importance, is attributed to Zenas Wheeler, who first introduced it in 1862, at Gold Hill, Nevada. This was further modified by casting the tappet with the gib in place, an achievement credited to Prescott, Scott & Co., the predecessors of the Union Iron Works in San Francisco. So far, the invention of the tangent-cam, of the high single-piece mortar, and of the deep vertical mortar-block, are unclaimed by anyone who has succeeded in validating his pretensions. The use of copper plates in amalgamation was known in 1853.

The early development of the stamp-mill seems to have been rapid in California. The leading improve- discovery of gold by Marshall at Sutter's mill. It discovery of gold by Marshall at Sutter mill. It

seems remarkable, at first sight, that so much was attained in so short a time on the Pacific Coast, while in the Appalachian States, which furnished the models for the first Californian mills, the plans and specifications of Agricola were still being so closely followed. The differences between the ancient structure, used in Saxony and in other parts of Europe,

Medieval Stamp-Mill With Mortar-Box.

as shown in the accompanying cuts from the famous classic 'De Re Metallica', published in 1546, and the early square-stemmed Californian mill also illustrated



An Early California Stamp-Mill.

herewith, certainly is not material. The explanation of the phenomenon undoubtedly lies in the fact that the almost fabulous riches reported from California in those early days brought hither the more alert and capable and ingenious men, those fitted for the frontier not only by physical vigor, but by the genius for adaptation, which is a better word under the circumstances than 'invention'. In the South the gold deposits were relatively small, although Georgia alone is acknowledged to have yielded an aggregate to date of more than $18,000,000 of the precious metal. Nevertheless this is insignificant compared with the output from the West. As early as 1850 it is estimated that 50,000 men were engaged in gold mining in California, and the number had doubled within a year. In the South Atlantic gold region the lands were mostly held in large estates, and were worked by slave-labor as an adjunct to agricultural pursuits. Under such circumstances the chances were few for directing much mechanical skill to the problem of milling.

According to J. Ross Browne, quoting Ashburner, there were 280 quartz mills in California in 1858, with a total of 2610 stamps, representing an investment in construction-cost of more than $3,000,000. Even then the common blunders, still so familiar in mining, were witnessed and decried; men insisted upon trifling with Providence by building a mill before they were certain of a mine adequate to feed it; and on the mechanical side the millmen were disposed then as now to use an excess of water in the batteries, and to feed quicksilver with too liberal a hand. Methods necessarily varied within wide limits, for such a thing as standard practice could not arise while there was no standard type of mill in vogue. The behavior of the pulp in a battery responds with astonishing delicacy to every adjustment of weight,

of stamp, height of drop, number of drops per minute, height of discharge, and volume of water. If to these be added variations in the number of stamps in the battery the difficulties of drawing lessons from comparison of working conditions are rendered still greater. The 5-stamp battery was by no means the prevailing style, even twenty years after the first mills were erected on the California gold belt. Four-stamp batteries were perhaps more common, and the 6-stamp mill was often found. At Soulsby, Tuolumne county, a 20-stamp mill was running as early as 1867. The stamps weighed 500 lb. each, and made 60 drops per minute. The mortars were deep, and the height of drop was from 8 to 12 in. It is not absolutely certain how much reliance may be placed upon these early records of recovery, but in this instance J. Ross Browne is responsible for the statement, in his report to the Government on the Mineral Resources of the United States, that 90% of the gold content of the ore was caught inside the batteries, and 95% of the remainder on the first copper plate. Following the plates blanket concentration was employed, the concentrate being ground fine and amalgamated. The Hayward mill in Amador county is reported at the same time as crushing 80 tons per diem in two mills having a total of 56 stamps. The heaviest stamp recorded in the earlier days of the art of gold milling was at the Seventy-Six mine in Plumas county, which had 32 stamps weighing 810 lb. each, making 60 drops per minute from a height of 10 in. This plant was erected in 1865. There is a manifest disproportion between the factors going to make up foot-pounds of power developed per minute in this mill, and conditions were such as to suggest millmen's 'troubles'. It would be interesting to know details as to the character of ore crushed, and the recovery attained. Mr. Paul asserts that in the first decade or two after the gold-rush, the extraction in the Californian mills seldom exceeded 20% of the original assay value of the ore, and anything containing less than $20 per ton was considered low-grade.

It is evident that conditions were rapidly improving, and that the better examples of Californian mills had reached a higher state of perfection in construction and practice by 1870, when Dr. Rossiter W. Raymond prepared his most famous report on Mineral Resources. He states that prevailing custom had favored five stamps to a battery; two batteries were driven from one cam-shaft, and in some cases three. The standard stem was 3 in. diam., 10 to 12 ft. long, tapered as seen in the models used today. The 3½ in. diam. stem was also used, showing a growing tendency to gain efficiency through weight, the total being not less than 620 lb., to which the stamp-head contributed 200 lb., the tappet 70, and the shoe 95. At that time it was considered that a white-iron shoe should last six weeks, and a die 4 in. thick, weighing 60 lb., should have a life of five or six weeks. The worn-out shoe and die together weighed about 30 lb. According to this report the Princeton mill on the Mariposa Estate, using 500-lb. stamps, recorded a wear of shoes and dies of 1.54 lb. of iron per ton of ore. The California mill was practically evolved by 1870, only requiring modifications in detail.

Early Mining in California

Written for the MINING AND SCIENTIFIC PRESS
By JOSEPH McGILLIVRAY

After the discovery by John Marshall at Coloma, Eldorado county, the news readily spread, and the people nearest to the place rushed in—Mexicans who used the batea, Chileans also, and from the Eastern United States, the Georgians, who were familiar with the rocker. All these came with their special appliances. The galvanized pan from the first was readily put to use, and up to the end of 1850 there were not many improvements better than the rocker. This was in general use. In 1851 river beds were turned by wing-dams into cut channels, and also into flumes built of lumber sawed by whip-saw, carrying during low stage all of the water available in the rivers, permitting the washing up of the beds, where in many cases large amounts of gold were recovered. Also drift-mining was begun this season, and Bowie gives me credit for beginning that kind of mining. Water-wheels were also applied, raising water to mine the bars in long-toms. When the gold was on the bottom of creek beds the top material was stripped off by pick and shovel, and the rich gravel washed by long-toms, and in the following season, namely, 1852, ground-sluicing was commenced by getting a head of water on the top of the bank and sluicing the waste material down to the pay-gravel, when the bottom was shoveled into the sluice-boxes at the head of the long-tom. The first attempt at hydraulicking was made by a man near Nevada City, whose name I forget. He had quite a bank of deep gravel, I believe about 15 ft. He took some green beef-hides of which he made a hose by riveting with copper rivets, then took two pieces of wood, gouging a half-circle out of one side of each, strapping them together with hoops of iron fastened to the end of the hose. This was a success; it readily washed the bank of gravel down. Later sail-canvas, 22 in. wide, was sewed into hose of about 6 in. diam. with a copper shank and nozzle; the nozzles were of various diameters, from 1¼ up to 3 in. The canvas was woven very heavy, and as the pressure was increased so that the hose could not stand it, another hose was put over the first, and then rope netting was woven over the hose. Later sheet-iron ferules were put over the hose to keep them from breaking. This was continued until a head of 125 ft. or more was attained, when 7-in. galvanized iron pipe was used. This was generally employed with a short piece of strong hose attached to the nozzle. Larger pipes were next introduced, carrying water from an elevation into a cast-iron box or chest, with lugs on one side, to which short pieces of hose were attached, with their nozzles, giving a greater flow of water with which to wash the gravel. The 'gooseneck' came in about this time; it revolved on a circle, but did not have a second motion to elevate or lower the stream against the bank. Mr. Craig invented the machine which he called the 'giant' about 1866. It was followed by different inventors, each giving their improvement different names. While this development continued, larger ditches were constructed.

Theories of Ore Genesis of Fifty Years Ago

Written for the MINING AND SCIENTIFIC PRESS
By S. F. EMMONS

The mining industry fifty years ago was in its early infancy. Up to that time no silver mines were known to exist in the United States, and hardly any deep mines in the modern sense of the word had been opened, most all the gold produced having come from the placers. It is true that the copper and iron deposits of Lake Superior had been worked for about fifteen years in rather a small way, and the lead deposits of the Mississippi Valley for a considerably longer period, and in even a smaller and more desultory way; a few mines of gold, copper, and iron had been developed in the Appalachian region, but the Great Cordilleran system which for centuries had produced untold wealth in silver for the Spanish miners in Mexico, was within our boundaries practically untouched. The years 1859-1860 were remarkable in the development of our mining industry, for in them had occurred the Pike's Peak boom which had resulted in the discovery of the first gold mine in Colorado at Central City on the extreme eastern border of the Rocky Mountain range, and in that of the Comstock lode, a silver mine comparable in size with the bonanza mines of Mexico, which was situated on the western border of that mountain system. Between them lay a belt of mountains and elevated valleys about a thousand miles in width, then, and for many years after, an unknown wilderness, marked on the map as the 'Great American desert'.

This period was notable also for an event of different order but of equally far-reaching importance. This was the founding, by act of the California Legislature of April 1860, of the Geological Survey of California and the appointment by the same act of Josiah Dwight Whitney as its Chief. There are undoubtedly wide differences of opinion as to the immediate value of the results of this Survey, especially in the State which was so generous and far-seeing in its original plans, and which was for many years divided by it into two factions, for Whitney possessed in a superlative degree that peculiar faculty which the well known artist, Whistler, has aptly termed the 'gentle art of making enemies', and during his official life built up a party opposed to himself and his work whose intense bitterness it is hard at the present day to conceive. It were unprofitable here to enter into any discussion of the merits of this controversy in which, like every difference between strong and earnest men, there were undoubted merits on either side. It lasted for fourteen years, and was ended by another act of the legislature in 1874, which not only finally legislated the Geological Survey out of existence, but so effectually prevented its resuscitation that Whitney was obliged to resort to private funds to publish his reports, and all subsequent efforts to establish another State Geological Survey in California have been futile.

Whitney was a man of wide reading, a remarkable linguist, and of undoubted ability as a writer and reasoner; he was the first American geologist to study vein phenomena in the schools of France and Germany and for a long time the only one to keep posted on the literature of that subject, which in the first half of the century was exclusively European. Up to the time of writing up the great results of the Survey of the Fortieth Parallel from 1873 to 1876, his private library was the only library in America in which could be found anything like a complete set of the various individual work and of periodical literature bearing upon this subject, the few public libraries of that period being singularly weak in that branch. From 1847 to 1850 he had conducted, under Government auspices, the first geological examination of a mining district, that, namely, of the copper district of Lake Superior, and during the decade 1850-1860, under State Survey auspices, he had made studies of the lead deposits of the Mississippi Valley. Early in this decade he wrote his 'Metallic Wealth of the United States' (Lippincott, 1854), which is a succinct but masterly review, not only of the then known ore deposits of this country, but also of the more important mines of the world, preceded by a discussion of the various forms under which the metals are found in Nature, and what was known at the time with regard to their genesis. His choice as Director of the California Survey was no less an evidence of the wisdom of those who planned the work than was the—at that time—unprecedented generosity with which it was endowed, $20,000 being allotted for the first year's field work and $6000 for the salary of the Director. It does not detract from the merits of the founders of the work that under subsequent legislatures there were considerable periods during which State funds were often absolutely wanting for the work, and it had to be carried on by money furnished by Whitney individually, or for which he considered himself personally responsible. His planning of the work was equally broad and generous and introduced many new and unprecedented features into geological surveying, as practised in this country, the most important of which was the preparation of base maps for the geology, which should show not merely the political divisions and the courses of the principal streams, but should figure the relief of the surface, or its topography, as well. As the fame of this great Survey of the gold-bearing Sierras spread throughout the scientific world, the opportunities it offered for a thoroughly scientific study of a new and most interesting field attracted geologists of exceptional ability from various parts of the world. From Germany and a geological expedition to New Zealand under the Austrian Government came Von Richthofen, better known in later years for his elaborate monographs on the geology of China, as published at the expense of the Government of Prussia. From France came the singularly brilliant young geologist Remond, who extended his studies on the Cordilleran system into South America, but died of consumption before he had had time to complete his work.

From the Sheffield Scientific School of Yale came Clarence King and his friend, James T. Gardner, who spent four years as volunteer assistants under Whit-

ney and Brewer on the California Survey. It was while engaged in this work that King conceived the idea of making a geological and topographical survey of the whole Cordilleran region to be opened up by the proposed transcontinental railroad, which should serve as a basis for the development of the great metallic wealth that his leisurely trip across the continent on an emigrant train in 1863 had convinced him must exist in that region. This idea carried into practical operation by the exploration of the Fortieth Parallel from 1867 to 1878 was the most important factor in bringing about the organization by Congress in 1879 of the permanent United States Geological Survey, of which he was the first Director. Thus to Whitney's reputation as a geologist was indirectly due the founding of this great Survey, which it is generally recognized has done more for the development of the study of ore deposits than any similar organization in the world.

Whitney wrote his 'Metallic Wealth' about the same time that von Cotta was publishing the first edition of his well known treatise on 'Ore Deposits', which for nearly twenty years was the only other book on this subject known in this country. (Prime's translation was published in 1870), so that between them they represent pretty well the average condition of technical knowledge on the subject. Both men had had a longer and wider experience in actual examination of working mines than any economic geologists who had preceded them, and Whitney had the advantage over von Cotta, in that he had seen the ore deposits of America as well as those of Europe, and had spent years in the continuous study of definite groups of deposits, while von Cotta had only given his summer vacations to relatively short visits. Von Cotta was writing a special treatise, however, to be used by his students, and with German thoroughness he had assembled not only all the facts known to him with regard to the mining districts of Europe, but also all the varied, and at times contradictory, views held by different authorities with regard to their mode of formation. In reading his work, it is difficult to determine which of the views presented he believes in himself, or even if he actually believes that any one of them offers a satisfactory explanation of all the phenomena he describes.

Whitney, who had spent years in the field study of types of deposits unknown in Europe—the native copper ores of Lake Superior, and the lead deposits of the Mississippi Valley—is equally non-committal with regard to general theories of genesis. His theoretical chapters are more brief, more concise, and more systematically arranged than those of von Cotta, and, therefore, more easy to analyze. That he had made some advance on the ideas that he might have imbibed during his studies in Europe is shown by the fact that in his classification of ore deposits, unsatisfactory though it may appear in the present state of our knowledge, he had introduced some genetic conceptions as a basis of his greater subdivision. Von Cotta's classification was entirely dependent upon the outward form of the deposit, regardless of its possible origin. Thus, he makes two principle classes: those of *regular* and those of *irregular* form. The former is divided into *beds*, which include beds of coal, etc., together with placer deposits, and *veins* which take in most tabular or vein-like deposits. Under deposits of irregular form are included, first, *stocks*, which are sharply defined bodies—contacts, cave-filling, pockets, etc., and, second, *impregnations*, which are bodies without sharp definition. Whitney's classification makes three general classes. I. *Superficial* deposits, including all formed by surface agents, whether physical or chemical, such as placers, bog ores, etc. II. *Stratified* deposits, which includes (a) those constituting the mass of a stratified bed; (b) those originally deposited from aqueous solution but since metamorphosed; and, finally, this third great class of deposit, III, *Unstratified*, which includes the great bulk of productive ore deposits which, with one exception, would today come under the head of epigenetic deposits or those formed later than the enclosing rocks. This is a far more philosophic conception of the subject than von Cotta's, for it recognizes the three fundamental differences of origin in reference to their time relation to enclosing rocks. In subdividing his last great class he brings in, as did von Cotta, the distinction of form and he makes, like him, a *regular* and an *irregular* sub-class. The former is subdivided into, (1) *segregated* veins—that is, lenticular bodies more or less parallel with the apparent bedding of schistose rocks; (2) *gash* veins, which are confined to a given bed or rock-mass; and (3) *true* or *fissure* veins, which he regarded as the most important and permanent form of metallic ore deposits. Under *irregular unstratified* deposits, he grouped: (a) masses of eruptive origin; (b) disseminated ores in eruptive rocks; (c) deposits; (d) contact deposits, and (e) fahlbands. Deposits that come under the head of the last, or irregular class, he evidently had had few opportunities of studying and considered of relatively little value. It was the importance of evidence of vein structure of some kind in a deposit that he was evidently desirous of impressing upon the minds of his readers, as is shown in the following summing up: "(1) True fissure veins are continuous in depth and their metalliferous contents have not been found to be exhausted or to have sensibly and permanently decreased at any depth which has yet been attained by mining. (2) Segregated and gash veins and the irregular deposits of ore not included under the head of veins, and not occurring in masses as part of the formation cannot be depended on as persistent, and they generally thin out and disappear at a not inconsiderable depth; at the same time they are often richer for a certain distance and contain larger accumulations of ore than true veins, although not of the same permanent value."

This very decided dictum of Whitney's, which was after all only a concise statement of the then generally entertained opinion, is very likely in great measure responsible for the popular prejudice especially among miners and prospectors in favor of the supposed *true fissure* vein, which economic geologists of later years have found it so difficult to combat, and which doubtless held back the development of many mining regions till after the remarkable wealth

and permanence of the Leadville deposits had demonstrated its falsity. On general theories of genesis, Whitney touches but lightly. (1) The theory that veins originated contemporaneously with the enclosing rocks he says "may be dismissed at once as entirely at variance with all the facts and as unworthy of consideration." (2) The theory "that veins have originated in the filling of fissures by injection of metallic and mineral matter in a state of igneous fluidity from below" he likewise rejects "as entirely untenable" from a consideration of the facts observed. (3) "The theory of formation by sublimation, according to which vein-fissures were filled by the volatilization of metallic matter from the great centre of chemical action beneath—namely, the ignited interior of the earth", he considers of very limited application in regular fissure veins, although in contact deposits and some other irregular forms of occurrence—notably, in mercury deposits—he considers "that some form of sublimation was very probable." (4) Werner's theory of chemical precipitation from solutions which entered the fissures from the surface downward, he says "pre-supposes a number of impossibilities, and has ceased to have the weight which was once attached to it." (5) The theory of lateral secretion he considers "to be more in accordance with all the phenomena of veins than any other one yet proposed." Furthermore, he admits that "some ores and metals do occur in rocks of undoubted igneous character in such a way that they must have had an origin contemperaneous with that of the mass in which they are disseminated. But these deposits do not belong to the class of regular veins." If veins had been the result of igneous action, he argues, we should expect to find in them the minerals common in eruptive rocks, "such as feldspar, hornblende, augite, olivine, and the like." On the contrary, "the usual gangue minerals, quartz, calcite, heavy spar, etc., according to the researches of Bischoff and other eminent chemists, cannot possibly have been introduced into vein-fissures * * * in a state of igneous fluidity, or by sublimation." To the theory of ascension, or of deposition from hot spring waters, or to the origin of the waters which carried the metallic minerals in solution, he does not refer.

In his practical application of theories to the deposits he had occasion to study in the field, he was a little more definite. Thus, in 1855,[1] he had given a fairly correct explanation of the origin of the black band copper ores of Ducktown as the result of electro-chemical action that produced the oxidation and leaching down of copper-bearing pyrites by surface waters; thus correcting Tuomey, the State Geologist of South Carolina, who had wished to bring in the agency of heat to account for their formation. Whitney's idea was a secondary enrichment that was stopped at the water-level; his error was that he thought it was a black oxide of copper, and that it was the hardness of the zone of underlying ore that stopped the oxidizing action. Of the iron ores of Lake Superior and Missouri, which were described as dome-shaped deposits, or elongated ridges of remarkably pure iron oxide, he wrote in 1856[2]: "They are simply parts of the rocky crust of the earth, and like other igneous rocks have been poured forth from the interior in the molten or plastic state." Of the magnetite bodies of northern New York, which he regarded as lenticular bodies included in and conformable with the enclosing gneissoid rocks, he said: "The facts seem to indicate that they are the remains of pre-existing igneous masses which have been broken down * * * * and deposited in the depressions of sedimentary strata in the process of formation." On the other hand, of the iron ore-bodies included in quartzites which he regarded as interstratified, he says: "They * * * seem to have been of sedimentary origin, (and to) have been originally silicious sand which has since been metamorphosed." Their original presence in the quartzite, he would have brought about either as a precipitation from ferriferous solution, or as sublimation of metalliferous vapors coming from below. The eruptive origin of the iron ores of Lake Superior he maintained long after all other geologists who had studied them, except his pupil and disciple, M. E. Wadsworth, had come to an opposite conclusion. He was equally persistent and uncompromising in retaining the term Azoic for all the pre-Cambrian rocks, and rejecting Dana's term Archean, which was proposed as a compromise until further investigation should prove more definitely whether they really contained relics of organic life or not.

In his 'Metallic Wealth', in discussing gold in California, he still holds to Murchison's view that gold is found only in the older rocks, as old at least as the Paleozoic. "There is room for doubt," he says, "whether the great gold deposits of the world did not originate exclusively in the Paleozoic strata, since we are not aware that rocks which have been proved to be of Azoic age have been found to be auriferous." He later modifies this rather narrow view by remarking that gold "only becomes evident after the strata have been metamorphosed or invaded by igneous and eruptive rocks," and states that: "In general the quartz veins may be supposed to have originated at the time of the metamorphic action on the strata themselves; and where there are igneous rocks in the immediate vicinity the development of the metallic contents of the adjacent veins is usually ascribed to their presence, since it is so often found that the metalliferous deposits are intimately associated with eruptive masses. It is not necessary to suppose, however, that these phenomena throughout the world were confined to any particular geological epoch; on the contrary there may have been a repetition of similar conditions at periods of time very distant from each other." The wisdom of this modification of Murchison's theory later found confirmation in the discovery by one of his own assistants, Clarence King, of Jurassic fossils in the gold-bearing slates of the Sierra Nevada, thus proving that the gold must have been introduced into them at some period later than the Jurassic.

The lead deposits of the Mississippi Valley, whose study on the Wisconsin Survey he completed just be-

[1] Am. Jour. Sci., Nov., 1855.

fore going to California,[3] he regarded as formed contemporaneously with the limestones in which they occur, possibly somewhat concentrated or segregated by circulating waters in later times. Forchhammer had recently published his studies on the composition of sea water, which had shown, among other facts, that certain sea plants contain sulphur. Whitney conceived that the early oceanic waters contained metallic salts in solution, and that decaying organisms had evolved sulphuretted hydrogen in sufficient quantity to precipitate them as sulphides. It remained for Chamberlin, who made later and more detailed studies of this region, to attempt to explain why the deposits were localized in this region rather than any other by endeavoring to reproduce the topography of the region in Lower Silurian times and indicate the oceanic currents that would probably have collected masses of sea-weed in an eddy in that region, resembling the Saragossa sea. It is possible that this idea may have accounted in some measure for Whitney's persistence in regarding the copper-bearing rocks of Lake Superior as of Potsdam age, for if they were admitted to belong to the Azoic system, there could have been no organisms there to precipitate the copper in its native state.

It may appear that the preceding account of Whitney's work and opinions has been unnecessarily prolix, inasmuch as it is difficult to determiue from it any definite set of theories and beliefs with regard to the origin of ore deposits that Whitney persistently held to, and he was a man pre-eminent for persistence in an opinion that he had once definitely adopted. It has, however, been intentionally made so, in order to show the very uncertain and tentative condition of the public mind on these subjects, a condition that the writer found to obtain with but very moderate improvement, except on the lines of general geology, when twenty years later he undertook his first special study of a mining district. Speculations and hypotheses were not wanting, but criteria had not been established, by actual study and demonstration, by which one could determine that one theory or view was applicable to a given deposit to the exclusion of all others. Hence, if one looks through the reports on mines made by mining engineers in that twenty-year period to demonstrate whether or not the deposit reported on is such as would justify the expenditure of a considerable amount of money for its development, he finds that most of them contain either no reference at all to the strictly geological relations of the deposit, or that such as is given is of a very perfunctory nature, confined to showing that it is a true fissure vein or bears some relation to one, and hence may be expected to continue indefinitely and probably grow richer in depth.

A rather exceptional report,[4] considering the ability and wide experience of the man, and the great importance of deposit, is that of F. von Richthofen on the Comstock Lode, made in 1865 for the Sutro Tunnel Company, with the object of showing that the ore would probably continue down to the depth at which it was proposed to cut it by the tunnel. Von Richthofen, evidently realizing that few of his readers would have any familiarity with matters geological, enters into somewhat elaborate explanations of quite fundamental matters. Thus, he gives the following characteristics of *true fissure* veins: (1) that they cut rocks of different kinds; (2) that they extend to an indefinite depth; (3) that they show evidence of dynamic action; (4) that they are ordinarily connected with the ejection of some eruptive rock; (5) that they are filled mainly from below and essentially by chemical action. He then says that various agencies have been advocated by different persons as the sole origin of veins, namely, infiltration from above, from the walls, from thermal action; but experience has shown that all these have been more or less simultaneously active in the filling of every true fissure vein. Thermal spring action would not explain the decomposition of the country for two miles to the east of the Comstock Lode; hence, the filling of the fissure must be regarded as the result of solfataric action, a solfatara being a vent for the violent emission of steam at or near an active volcano. Every solfatara passes through two stages: (1) one in which steam is accompanied by gaseous combinations of fluorine and chlorine; (2) by those of sulphur. A later phase, marked by the emission of carbonic acid gas, is no longer solfataric. In the Comstock silica was deposited in the first stage, and the fissure being opened again, the metallic minerals were then introduced as the second stage. As for the source of the water which furnished the steam and acted as a solvent, he says the ocean was too far away, but the waters from the Great Basin, which had a similar composition, penetrated to the heated region, thus furnishing the same source for fluorine and chlorine that they are supposed to have in active solfataras. "As for the source of the mineral substances", he says, "we have to look for the action of these elements on the surrounding rocks." This was the report of a professional geologist of the very highest standing and is, as before stated, a rather exceptional one. The average report at that time is better typified by that of A. Sutro on the same subject, in which he is endeavoring to persuade capitalists to subscribe to his tunnel scheme, and which is probably a paraphrase of that of von Richthofen. It says: "The Comstock Lode is a true fissure vein, * * * through which open fissure ascended steam and vapors, gases, acids, sulphur, chlorine, and fluorine, carrying with them silica and metallic particles in a volatile form, which, in course of untold ages, gradually filled up the fissure, and after undergoing many chemical changes, formed what is now known as the Comstock Lode." In the much more detailed and exact study made of the Comstock Lode by King and Hague in 1867-8, Mr. King declines to go into abstruse speculations with regard to the ultimate origin of the metallic contents of the Lode, it evidently being his idea that a greater accumulation of exact facts derived from exhaustive studies was necessary before such a discussion could profitably be entered upon.

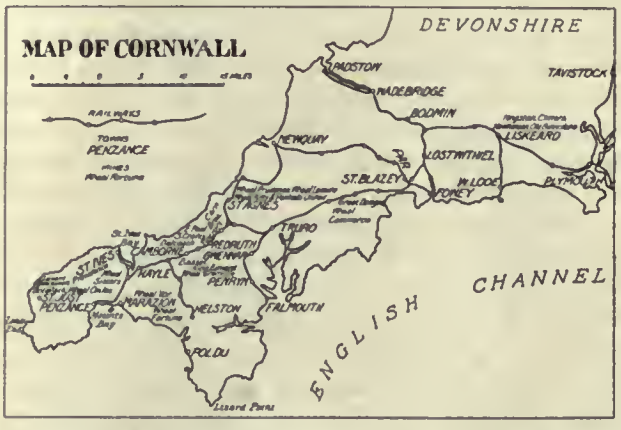
Reminiscence of Mining in Cornwall

Written for the Mining and Scientific Press
By Joseph Vivian

The rise of mining in this country appears only in dim tradition of the 'Tin Islands', as our native land was known to traders from the Eastern shores of the Mediterranean. Whether the Celtic natives discovered for themselves that many of our valleys were full of alluvial tin, or whether the enterprising adventurers of Phoenicia and Palestine made the discovery for them, it is beyond doubt that long before the Christian era a great trade existed in the export of the metal from 'Cornuwales', and that if much of it were shipped direct from Marketjew a considerable quantity found its way over land to the Eastern seaboard of Britain and across the strait to France and to that south of Europe where the tired Briton of today seeks the restoration of his vigor. Down through the ages tin has formed the staple product of the Western Peninsula, until copper became a rival and for a century or more took the first place. One is too apt to forget how, during the last hundred and fifty years, mine after mine became a great producer of copper, until Cornwall took the foremost place in supplying the world with that metal or the ore from which it was smelted. There was a time when the smelting was carried out at home, but by and by Cornishmen found it to their advantage to ship the ore to Wales, thereby making a great saving in freight on coal. Thus arose those great works at Swansea and elsewhere in the Welsh coalfields, which, now no longer getting their raw material from the Duchy which gave them birth, import their ores from the ends of the earth. But I have no intention of dipping further into a history which would naturally be the subject of great research and fill perhaps many volumes. My object is rather to relate, either from my memory, extending over about three-quarters of a century, or from the memory of those whom I intimately knew, whose experience extended back to the last quarter of the eighteenth century, events which may throw an interesting light on the spirit and achievements of an age which in the midst of the turmoil of today is in danger of being forgotten.

Camborne and the immediately adjacent parishes were from early times the home of a mining people some of whom attained to great wealth and founded families and estates which still testify to their energy and success. These were men of true and indomitable enterprise, who realized the possibilities before them and were not easily turned aside. Dolcoath had been eminently successful in the eighteenth century or before, but there came a time when partly, it is probable, through the difficulty of draining the workings, the mine was abandoned. But toward the end of the century Andrew Vivian, a man of dauntless resolution as well as of practical knowledge, entertained the idea that Dolcoath would pay to resuscitate. He placed his views before Lord de Dunstanville, the owner of the land and mineral rights, who was not slow to recognize the probability of profit to his estate by the re-opening of this old mine, and not only granted Vivian the 'sett', but took a large interest in the company which was formed to work it. Great results came of this venture, the mine has worked continuously for more than a hundred and ten years, and the Tehidy family has reaped more than a million sterling from this mine alone. So much for the enterprise of Andrew Vivian and the readiness of Lord de Dunstanville to give him every encouragement. Before this, mining was for several years at a very low ebb, but the early years of the nineteenth century witnessed the flowing tide.

North Roskear was in the land of Mr. Pendarves. He granted the sett and followed the example of Lord de Dunstanville in embarking largely in the company of adventurers. Many people, however, formed a poor opinion of the speculation and there was considerable difficulty in getting the money paid up to carry on the work, when a well known firm of



merchants who held one-eighth of the shares had the mine inspected and on the report of their agent determined to relinquish their interest. This was, or threatened to be, a serious blow to the company. A meeting of the remaining holders was called, and it was generally thought that the mine should be abandoned. The purser, however, advised that before deciding on this step they might hear what the manager had to say. The manager was called and gave his report which did not appear to shake the resolve to give up the sett, until he said that if the shareholders had decided not to go on, he had a favor to ask from them, namely, that they would lend him the machinery which was only of small value, for a few months, when he would carry on the work at his own cost. He was a young man of moderate means as he explained, but was so confident of success that he was prepared to take the risk for a limited period. His confidence was contagious, the company there and then resolved to go on, and in three months from that meeting, and for many a long year after, North Roskear was a highly productive and prosperous copper mine, and Mr. Pendarves, as the owner of the dues and the largest shareholder, reaped a handsome fortune from it.

These discoveries in the first quarter of the century were, however, but the forerunners of many others which soon made the weekly copper Ticketings held at Truro, Redruth, Pool, and Camborne important meetings both to the miners and to the cop-

per smelters, and at Hayle and Portreath might always be seen many hundreds of tons of ore on the wharves waiting for shipment to Welsh ports by the coasting scooners which loaded back from thence with coal for the mines and iron foundries. It was then no uncommon thing to see the harbors of Hayle and Portreath crowded with these sailing vessels, where now hardly one is seen, the diminished traffie being mastered by half a dozen steamers. This brings to mind the well authenticated story that 30 of these coasters sailed out of Hayle on one tide and ran into such a fearful tempest that only one of them escaped shipwreck. This has been ever since called the August gale, as it occurred in that month.

To return, however, to our subject, the new spirit thrown into mining in a measure by the success of Dolcoath and North Roskear was rewarded by great discoveries of copper at such mines as Wheal Seton, West Seton, Wheal Basset, West Basset, South Frances, Crenver and Wheal Abraham, Carn Brea, North Pool, and several others among which may be particularly named Wheal Buller, the discovery of which reads like a romance. The manager of North Roskear having business at a mine meeting in Gwennap walked there, and taking a short cut across country passed over the downs on the high ground east of Carn Brea hill. There, engaged in cutting and faggoting furze, he found an old man whom he recognized as a former acquaintance and stopped to speak to him. While chatting he noticed among the roots of the furze stumps bits of gossan, and handling one or two remarked that they were very kindly stuff. "Yes," said the old man, "I do think they are." "What is the name of this place?" he asked. "Wheal Blackbird," was the reply. He then continued his journey and at the mine in Gwennap met among others Stephen Davey and Richard Davey, well known mining men of Redruth. He told them of what he had seen in the course of his walk and asked who was the owner of the land called Wheal Blackbird. They said Mr. Buller, whom they represented as mineral agents or 'tollers'. A few days after this interview Frank Pryor, who occupied a prominent position in mining circles, came to North Roskear and asked the manager if he could recommend a good mining sett. "Yes," he said, and told him of Wheal Blackbird. "Thank you," said Mr. Pryor, "I will apply for it." But when he made the application to the Messrs. Davey they stated they were going to work it themselves. This they did, forming a cost-book company in a hundred and twenty-eight shares of which they retained one-half. A call was made of £10 per share and before the sum total of £1280 was spent, a lode was opened up which gave a profit on copper of more than £300,000, and shares which cost £10 reached a market value as high as £1400 each.

After Dolcoath had held its own for some forty years as a copper mine, it began to show the sere and yellow leaf of exhaustion. The deeper levels were abandoned and under water, and the ore remaining in the upper levels would not pay for keeping the mine going. Then the question was: 'To be or not to be'. The advice of experts was sought, one on behalf of Lady Basset, the owner of the mineral rights, and another on behalf of the company that held the lease. These experts, strange to say, agreed in the advice to unwater the bottom and to re-commence working in depth. This advice was taken and justified by the immediate raising of tin, with the result that in a short time Dolcoath became the greatest tin mine of the county, surpassing every tin mine in the world except, perhaps, one. A few years ago, the present Dean of Grahamstown, then Canon Missioner of Truro, told me that he was making a visit to Tasmania and would be ashamed to own when he got there that although coming from Cornwall he had never been down a tin mine. The hint was taken, permission asked and granted with the unfailing courtesy of the late Capt. Josiah Thomas, that Canon Carter should go to the bottom of Dolcoath. And so it happened that when he reached Tasmania the Canon could tell of his visit to a mine more wonderful even than their own Mount Bischoff. Since Dolcoath became a great tin mine, the depth of its workings has doubled and is now considerably over half a mile and still it goes down from "deepest depths to deeper still."

The strange thing is that the change of the lodes from copper to tin in Dolcoath is only an example of what is found in practically all the mines of the district, and there are many of these old mines once rich in copper, but now derelict, which as tin is more and more wanted will hereafter be re-worked and then will be repeated the success already attained in a mine which was so near being abandoned. West Seton with a good lode producing a considerable amount of tin, but given up for the lack of a little more of the spirit of enterprise may be cited. South Tolgus, rich in copper for a depth of 140 fathoms, abandoned just as the lode was developing tin is another. Forty years have passed since this mine was abandoned and from that time to this the dumps have paid to work on tribute for tin, and a tributer, who worked in the bottom of the mine up to the last, sent up tinstone by which he got £40 for his last month's work.

There are, however, other districts which have not been explored to nearly the same depth as the Camborne mines. Gwinear on the west has had several rich copper mines, and one which is said to have produced silver to the amount of £80,000 but none of these mines have been worked to any considerable depth. And the parish of Perranzabuloe has had its West Chiverton on the east and its St. George and Wheal Leisure on the west, notable and profitable mines in their day, but the great part of the parish lying between has never been fairly prospected and offers today the probability, with a comparatively small outlay, of finding prizes equal to any of those which have gone before. West Chiverton was worked for lead and silver by a gentleman called Cookney. He died and left the property to his widow who determined to sell it. When it was known to be for sale, a syndicate was formed with the object of purchase. Negotiations were entered into with the London agent, and it was found that the price asked was £30,000. The syndicate tried to get it for less. In the meantime two other men thought they would like to buy it. One of them, a

Cornishman, had known Mrs. Cookney, and on the strength of this business acquaintance, they determined to call on her. They found, however, that she had changed her residence, and when, after much enquiry they reached her door it was 9 o'clock at night. The footman who answered the bell, said Mrs. Cookney does not see visitors on business at this hour. But one of them wrote a few words on his card and asked the man to take it to his mistress. They were then granted an audience and told that the sale was left unreservedly in the hands of her solicitor, to whom, at their request she gave them a short letter of introduction. The next day they called at his office, and found that the other party had the option of taking the property up till noon on the next day. If they would call at that hour, he would, unless the others had accepted, be prepared to deal with them. Coming to his place the next day as the clock struck 12, they found that the property had not been sold, and without hesitation closed the bargain at £30,000. Going out fortified with a contract note, the Cornishman said to his friend: "Where are we going to get the money to pay for it?" "All right," said the other, "come along with me." They went to the office in the city of a man who commencing life as a barber in Cornwall had acquired considerable substance on the London mining market. "Well," he said, when they walked in, "what do you want?" "We want £30,000." "Indeed," he said, rather sarcastically. "Yes, and when you know on what grounds, you are going to let us have it." "Oh! of course," was the reply, "and what are these wonderful grounds?" "We have bought West Chiverton." "Oh, no! I know better than that." He was a member of the syndicate which was hoping to get the mine for something less. When, however, he was shown the contract and was told that if he would advance the money, that money should be the first charge, and that after that was paid they would all three share equally, he consented to the terms. The property was transferred, the purchase money quickly repaid, and each of the three gained more than £40,000 profit. This happened about forty years ago. Some people profess to think that the mineral resources of Cornwall have been pretty well determined. There are others who hold that much less capital than has been spent somewhat lavishly in re-opening deep mines, would, if devoted to prospecting new ground, have struck ore and met with rewards equal to Wheal Buller or West Chiverton.

The outlook for the petroleum industry in California is highly encouraging. Such flattering oil prospects have been obtained in Kern, Humboldt and several other counties during the year as denote for this industry early enlargement. Our oil-producing territory covers an immense area, and although the deposits generally lie deep and are somewhat scattered they offer great inducements for the inauguration of new enterprises and the investment of capital. —January 7, 1893.

Twelve and three-quarters tons of cinnabar ore, from Chapman's mine, 3½ miles south of San José, yielded 64 flasks of quicksilver.—July 13, 1867.

Early Smelting at Cerro Gordo

Written for the MINING AND SCIENTIFIC PRESS
By FRANCIS DRAKE

Lead smelting in the early seventies was carried on in rather a different manner than it is today. I went to Cerro Gordo, in Inyo county, in September, 1874. The mines there had been producing what I have seen described as a 'flood of silver-lead'. They were owned by Egbert Judson and Mortimer W. Belshaw, as to one-half, and Victor Beaudry as to the other. The ore as it came from the mines was sorted, the galena and waste being picked out; it was then divided on the dump. One wagon load went to the furnace owned by Messrs. Judson & Belshaw, and the next went to the furnace owned by Mr. Beaudry, and so in turn the galena was weighed, but no such trouble was taken with the ordinary ore. I remember Mr. Belshaw defending the separate treatment of ore by saying that the rivalry between the two furnaces treating the same ore tended to make those in control put forth every effort. There certainly was rivalry. One of my duties was to try to find out the size of the other fellow's bullion pile, and if either of the furnaces was shut down longer than usual for the almost daily patching of its brick walls, there was gratification in the rival office.

No attempt was made to weigh the quantities of materials going into the furnace.* The fuel was charcoal and the quantity to each charge was a 'box' of indefinite capacity as it had only three sides and was unequally filled by the charcoal passer whose work was to fill the box from the charcoal heap and inject its contents into the furnace when told to do so by the feeder. The superintendent exercised some supervision over the number of shovelfuls of galena, quartz, and slag to each charge, also told the ore-wheeler what proportion of the different colored ores to wheel on to the charge floor; but the feeder put in as many shovelfuls of this ore mixture as he thought the furnace would stand and keep running.

The furnaces were of an oval shape at the tuyere level, being about 4 ft. 6 in. on the longer axis and about 3 ft. on the shorter one. They had five tuyeres, two on each side and one at the back, and were about eight feet from the tuyere level to the charging door. The superstructure commenced about four feet above the tuyeres, was of common brick, and was supported by four iron columns. The walls of the furnace below this superstructure were made of large radial bricks which were made of local fire-clay and crushed quartz. They were not burned and were excellent flux for the highly basic ores which were being treated. The production was on exceptional occasions as high as thirteen tons of bullion per day.

The level of the charge was kept as low as possible without having a flaming top, and large quantities of ore were blown out of the shaft and thrown over the dump as flue-dust. At the Belshaw furnace this flue was about six feet long and extended downward at an angle of about 30° from the horizontal,

*Weighing of the furnace charge was introduced at Cerro Gordo in 1878 by Fred F. Thomas.

from one side of the superstructure of the furnace to a brick chimney, which extended a short distance above the roof of the furnace building. The dust was taken out of a door at the base of this chimney. Probably someone will write in your centennial number of the wasteful methods of this generation, calling attention to the 25 to 30% of value which we allow to go to waste from our copper concentrating works.

Late in 1874, a water-jacket was introduced to take the place of the air-dried bricks. It was of the same horizontal section as the brick furnace, except that the inside was a foot longer and wider. This was to allow space for a lining which was made of air-dried bricks half as long as those previously used. It was thought that it would never do to run it without a lining. The jacket was made of the best wrought iron obtainable and all in one piece, that is, it was not sectional. It had large opening for the insertion of water-cooled tuyeres, and these projected through the jacket about six inches.

This jacket, if not the first, was one of the first used in lead smelting on this Coast. It was designed by Mr. Belshaw and William E. Goodrum, the latter being the furnace superintendent at the time, and made by Hinckley, Spiers & Hayes, of the Fulton Iron Works. It was made to stand a boiler pressure and had a cylindrical steam drum at the back, to which it was connected by two 3-in. pipes about 3 ft. long. This drum was connected to the steam drum of the boiler and the bottom of the jacket was connected to the bottom of the boiler. The level of the water in the boiler was somewhere in the pipes connecting the drum to the jacket. This arrangement caused some economy in boiler fuel and was in use until the jacket became leaky, after which it was run as jackets are now. Water in the furnace was not conducive to good smelting and besides we had to be economical with it as it cost a cent and a half a gallon. The water-jacket furnace was a great success in that it saved the suspensions of work to patch up the walls of the furnace. It had occasionally to stand the blame for faulty metallurgical work though, as freeze-ups were sometimes ascribed to a leak in the jacket when the cause was something else. As the bullion was sent to San Francisco an endeavor was made to make it carry as much silver as possible and as the ores of the furnace owners were ferruginous, quartz ore was bought from any one who liked to bring it in. On one occasion supply of this ore was short and barren quartz was used. The bullion carried just under one hundred ounces to the ton. Mr. Belshaw came up from San Francisco and asked us why we did not put in some silver dollars. He said that it would have paid well to do it as he got a much better price per ounce when the grade was above one hundred ounces per ton.

The bullion was sent to the Selby works at Black Point, where the silver was separated from it, and the lead refined. It is said that the Selby people had agreed to take all of the production during a term of years, under a contract to pay a certain royalty on the refining process the right to use which was owned by Judson & Belshaw, and they were much embarressed at the quantities that were being sent. Judson & Belshaw magnanimously agreed not to enforce the conditions of the contract.

The freighting of the bars to San Francisco was a problem. Local freighters were tried, and the result was accumulations of thousands of bars at Cerro Gordo and other points. At one time 42,000 bars, weighing from 85 to 87 lb. each, were on hand at the furnaces. Eventually the Cerro Gordo Freighting Co. was organized, with R. Nadeau, of Los Angeles, as the principal owner, and gradually the accumulations were reduced. The organization of this freighting company is worthy of a passing note. Almost all of the country through which the freighting had to be done was desert, and water was scarce and often of poor quality. Stations were established at intervals, water was piped to them from the nearest springs, in some cases several miles distant, and supplies of food stocked for man and beast. The teams were kept on each run the same as stage teams are, going in one direction one day and back the next. The wagons went straight through with their loads. At first the bullion went to Los Angeles, but when the railroad got over the Tehachapi pass it came to San Francisco by way of Mojave.

Since those days the waste and slag dumps have been picked over at least once, and I understand that the present owners propose to go through them again. One of the dumps was the cause of much excitement. In a gossan which had been thrown out as valueless, gold was found by an old Mexican woman. Soon the dump was alive with men, women, and children, and the amount of gold won is unknown. It reached thousands of dollars, as some of the pieces were very rich, containing ounces of gold to the pound of rock. Many fruitless efforts were made to find the place in the mine from which the rock came.

THE ARGONAUTS

By Joaquin Miller

Lo! when the last pick in the mine
Lies rusting red with idleness,
And rot yon cabins in the mold,
And wheels no more croak in distress,
And tall pines reassert command,
Sweet bards along this sunset shore
Their mellow melodies will pour,
Will charm as charmers very wise,
Will strike the harp with master hand,
Will sound unto the vaulted skies,
The valor of these men of old—
These mighty men of 'Forty-nine,
Will sweetly sing and proudly say,
Long, long agone there was a day
When there were giants in the land.

(Extract from poem 'Joaquin Murietta.')

An alarming report that the fleet of British war steamers, pretended to have been built for the Chinese Government, is now preparing for an attack on San Francisco, lacks confirmation.—February 13, 1864.

Looking Backward

Written for the MINING AND SCIENTIFIC PRESS
By H. F. DEXTER

Of the early history of the MINING AND SCIENTIFIC PRESS, I can speak only from hearsay and what I have gathered from the files of the paper itself. The paper was founded on May 24, 1860, by J. Silversmith, who, in partnership with J. H. Winslow, printed the first number under the title THE SCIENTIFIC PRESS. "A Journal of Science, Art, Manufactures, Chemistry, Invention, etc," the object of the paper being set forth in the prospectus contained in the reproduction from the first issue printed elsewhere in this number. On the front page of the issue dated June 9, 1860, a notice of the dissolution of partnership between Winslow and Silversmith

Alfred T. Dewey.

was printed and the announcement was made that Silversmith would continue the publication of the paper. In the following issue appeared another notice to the effect that the paper would be published by J. Silversmith and edited by "An Association of Scientific Men." In the issue of September 1, 1860, it was announced that the paper would be published daily during the fair that was to be held in the Mechanics Pavilion during that month. It was also announced in the same number that owing to their growing importance the mining interests of the State would thereafter be the chief feature of the paper. On October 20, 1860, the name of the paper was changed to THE MINING AND SCIENTIFIC PRESS AMD MINING ADVOCATE. "The Association of Scientific Men" seems to have become tired of editing the paper very soon as in the issue of November 30, 1860, the name of J. Silversmith appears as both publisher and editor and continues so until October 7, 1862.

On January 19, 1863, W. B. Ewer joined C. W. M. Smith in partnership and they continued to publish the paper until December 14, 1863, when another partnership was formed consisting of W. B. Ewer, C. W. M. Smith, and A. T. Dewey under the firm name of Dewey & Co. Mr. Dewey came from La Porte, Sierra county, California, where he had been for five years publisher of the *Mountain Messenger*, and previous to that had been engaged in the newspaper business respectively in Westfield and Springfield, Massachusetts. This partnership continued until August 8, 1868, when Smith disposed of his interest to Dewey and Ewer who continued as partners until the Dewey Publishing Company was incorporated in December 1891.

The early owners of the paper seem to have been of a migratory nature; possibly they found it "cheaper to move than pay rent." The original office

Warren B. Ewer.

was in the Government House, corner of Sansome and Washington streets. On January 11, 1862, the office was moved to 522 Merchant street; on April 9, 1862, to the State Capitol building, or as it was afterward designated, the Federal building, corner of Battery and Washington streets; on September 21, 1863, it was moved back to the Government House; on April 10, 1865, to 505 Clay street; on August 8, 1868, to 414 Clay street; on October 1, 1871, to 338 Montgomery street, southeast corner of California street; on July 13, 1874, to 224 Sansome street, southeast corner of California street; and on July 28, 1877, to 202 Sansome street, northeast corner of Pine street, where it was when I joined the force.

When on the morning of May 1, 1878, I stood on the platform of a Silver Palace car passing over the summit of the Sierra on the Central Pacific railroad, gazing at the snow-clad mountains, for at that time the view was very much less obstructed by snow-sheds than now, the railroad company depending

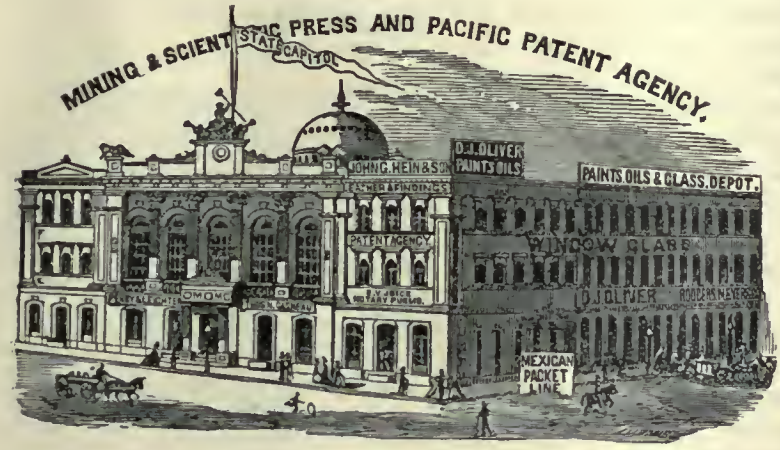
more upon snowplows than sheds to keep the track clear, I had no idea that thirty-two years later I would be helping to celebrate the fiftieth anniversary of the founding of the MINING AND SCIENTIFIC PRESS. As a boy I had a great desire to see California, and an opportunity had presented itself whereby I expected to earn enough money to pay my expenses for the trip and then I would return to New England and settle down for life. In a few hours we were down on the floor of the great valley which was carpeted with green grass and wild flowers, and late in the afternoon we arrived at the Market street station in Oakland, coming in by way of Stockton, Livermore, and Niles. This station has since been removed, the Overland route having been changed to that by way of Suisuin and Benicia. The day was bright and warm, and coming from the bleak climate of the Eastern States the transition seemed to me most beautiful. The next day I spent looking around San Francisco, visiting among other places of interest the celebrated Woodward's Gardens, which have now been out of existence many years. The following day I began my duties in the office. The business office was then in a three-story brick building, which was afterward torn down to make room for one erected by the Anglo-Californian Bank. The editorial, composing, and press-rooms were at 414 Clay street. As previously stated the MINING AND SCIENTIFIC PRESS was owned by the firm of Dewey & Co., publishers, consisting of A. T. Dewey and W. B. Ewer. They also established the *Pacific Rural Press* in 1871, the leading agricultural paper on the Pacific Coast. Affiliated with them was the firm of Dewey & Co., patent agents, composed of A. T. Dewey, W. B. Ewer, and George H. Strong.

There was at that time a great struggle between the miners and farmers over the débris question. This finally resulted in the creation of the California Débris Commission. The bitterness existing between the two factions was no doubt greatly ameliorated by the fact that the above mentioned organs of both were owned and controlled by the same firm, the members of which sought as far as possible to harmonize the interests of the two. The telephone was just being introduced and our office was among the first to have one installed, our number being 77. The following quotation from the MINING AND SCIENTIFIC PRESS of May 18, 1878, will be of especial interest: "The use of the telephone in this city has been marked by the character of enterprise which usually attends the introduction of progressive inventions among our wide-awake people. The American District Telegraph Co. has furnished a large number of the instruments to private parties, and has given the use of the telephone features which were original with them, but which from their plain advantages are now being introduced in other cities. Notable is the arrangement called the 'central system'. At their establishment on Sansome street, near California, they have a telephone department under the management of Mr. John I. Sabin. In this room each wire from the distributed telephones centers. If the owner of a telephone wishes to communicate with another owner in any part of the city he signals or calls the central office, and his wire is connected with that of the other party. There are now 100 firms centering in this office and each one can thus, at a moment's notice, be put in communication with any one of the 99 others. Thus any firm can communicate with another as man would speak with man, as the message goes direct without even the intervention of an operator. When a firm is called from the central office they are told the name of the party who addresses them by the central operator, so there would be no chance for the telephoners to impose on one another by calling wrong names. Each firm is furnished with a schedule of all the others which are in communication with the central office. As we have said, the manifest advantage of this centering idea is so great that the great cities at the East are thinking of following the example set them by the enterprising company in San Francisco." Out of this small beginning there has developed a system which now numbers nearly a hundred thousand telephones.

My work was at first in the engraving department. Several photo-engraving processes had just been invented and the firm had bought the right to use one from Leo Bok of New York. It was popularly known as the 'plaster process' and consisted briefly in photographing a line-drawing and printing the negative on a thin sensitized dry film of gelatine spread on a thin sheet of zinc. When immersed in water the parts of the gelatine not printed on would swell, thus forming a matrix from which a plaster of paris cast was made. Lye was poured over the face of the cast and allowed to dry thoroughly. A positive plaster cast or matrix was then made from the negative, the object of the lye being to prevent the two from adhering. A type-metal cast was made from the second matrix and mounted on a wood base, type high, when the figure was ready for the printing press. The weak point in the process was the difficulty of casting the type-metal plates from the plaster casts without cracking the latter. There was also difficulty in separating the two plaster casts when the shading was very fine. Another difficulty was that the printing of the negatives could only be done by sunlight, electric light not having come into use at that time, and in the prevailing cloudy weather in San Francisco, it was at times several days before any printing could be done. The process was adapted to such a limited variety of work that it was given up after a few months' trial and we returned to the use of wood cuts until the process of etching on zinc came into practical use.

In the meantime I had been called into the accounting department where I have since remained. At the time I first assumed my duties in the business department there were, as now, three kinds of money in circulation—gold, paper, and silver, but instead of being at par, each had its own value in the order named, gold being the highest, paper next, and silver the lowest. The difference between gold and silver was enough to drive gold out of circulation except where it was specially designated as being the medium of payment, hence nearly all promissory

notes stated the amount due should be paid in gold coin. Checks for amounts less than ten dollars were rarely used. Nearly all ordinary bills were paid in silver. In fact many of our subscriptions were paid in silver, the coin being shipped to us by Wells, Fargo & Co.'s express. It was not until several years afterward that money orders and checks came into general use for small amounts. Occasionally payments for subscriptions were received in small nuggets or gold dust, as still sometimes happens in the case of subscribers in out of the way districts.



MINING & SCIENTIFIC PRESS AND PACIFIC PATENT AGENCY.
STATE CAPITOL
PAINTS OILS & GLASS. DEPOT.
WINDOW GLASS
MEXICAN PACKET LINE

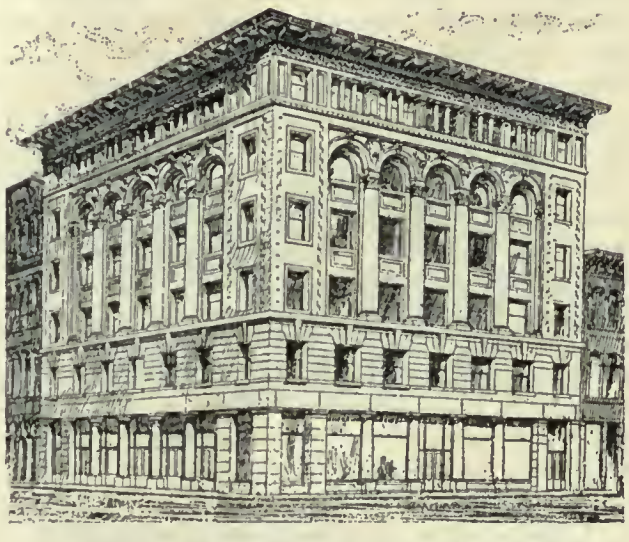
Old Capitol Building, Office of the Mining and Scientific Press 1862 to 1863.

In the fall of 1882 I went East on a visit and while there spent some time in New York trying to engage an engraver to come to San Francisco. There were plenty of engravers but none of them would undertake such a long journey. They thought it too far out of the world. In the fall of 1879 and during the year 1880 the firm published the 'Scientific Press Supplement', a semi-monthly which was intended to be to the MINING AND SCIENTIFIC PRESS what the 'Scientific American Supplement' was to the *Scientific American*. It never was popular and was so poorly supported that it was soon discontinued. In February, 1881, the company assumed the publication of *The Californian*, a monthly magazine which had been founded the previous year by Anton Roman, who at one time was the leading bookseller of San Francisco. It was published in our office a few months and then turned over to the Overland Publishing Co. and the title changed to *The Overland Monthly* under which name it continued to be published for several years. It was afterward purchased by the Southern Pacific Company and the title of the magazine again changed to the *Sunset*, which name it still retains.

In October, 1881, the business office was moved to 220 Market street, on the northeast corner of Front street. This change was made necessary as previously stated, on account of the tearing down of the building at Sansome and Pine streets. It was a fortunate move, however, as the new location was more central and on the principal thoroughfare of the city. In the fall of 1884 the editorial ,composing, and pressrooms were also moved to 220 Market street, quarters having been fitted up in the basement for the press-room and additional space secured for the editorial and composing rooms on the same floor as the business office. The advantage of having all departments of the business under one roof was immediately realized. Even this arrangement had its drawbacks, however, as we were obliged to furnish our own power and assume the responsibility of operating an elevator. It was at the time when gas engines were first coming into use and we installed one to supply power, and I believe we had our full share of troubles. Afterward when electricity came into use we put in a motor, and from that time on had little difficulty.

Building at 202 Sansome Street, Office of the Mining and Scientific Press in 1877.

Interior of Office at 202 Sansome Street.



Building 330 Market Street, Office From 1897 to 1906.

In the fall of 1891 Alfred Holman bought a one-third interest in the business and it was incorporated in December, 1891, under the name of Dewey Publishing Co. In June, 1893, Mr. Dewey sold the remainder of his interest to J. F. Halloran and the latter became general manager. Mr. Halloran had previously had considerable experience as a newspaper publisher, and also some experience in the mines, he was, therefore, naturally interested in the development of the MINING AND SCIENTIFIC PRESS.

In April, 1898, Mr. Holman sold his entire interest to Mr. Halloran, who, with Mr. Ewer, continued to own practically all of the stock until 1905, when T. A. Rickard purchased a controlling interest in the business.

In June, 1897, the office was moved to 330 Market street, northeast corner of Bush and Battery streets, where it remained until the memorable morning of April 18, 1906, when the whole business portion of San Francisco made a very sudden move. The story of the earthquake and fire is told elsewhere in this issue by Mr. Rickard.

The entire business passed into the control of its present owners in the latter part of 1905 shortly after T. A. Rickard severed his connection with *The Engineering and Mining Journal*. With him was associated his cousin, Edgar Rickard. Mr. Halloran retired at that time. Early in 1909 T. A. and Edgar Rickard established in London *The Mining Magazine*, a monthly periodical closely affiliated with the MINING AND SCIENTIFIC PRESS. The initial number of this publication appeared September 15 of last year. The favor with which the new magazine has been received indicates that it will realize to the full the expectations of its promoters.

Of the men under whose ownership the paper has been conducted during my connection with it I may be permitted to speak briefly. Mr. Ewer was well advanced in years and did not take any very direct interest in the business after I came into the office. What he did do was in connection with the editorial department. Mr. Dewey was the active member in the business affairs of the firm. He had a consuming desire to become a publisher of many papers which led him into several outside ventures in the way of fraternal publications. He was ever ready to adopt anything new in improvements which would enhance the value of the papers as was evidenced by his pioneer efforts in the introduction of the photo-engraving process and in the adoption of new machinery and appliances for the mechanical production of the paper. He was ever ready to get in touch with the best writers of the day, and it was largely through his effort and those of Charles G. Yale who was associated with the paper as editor, that such men as Guido Küstel, C. H. Aaron, C. A. Stetefeldt, Almarin B. Paul, George Davidson, J. S. Phillips, Melville Atwood, Henry DeGroot, Henry G. Hanks, and other leading men of their day became contributors.

Of the present ownership and management I need not speak at length as they are giving evidence every week of their success in making the MINING AND SCIENTIFIC PRESS the best paper of its kind in the world. It is a great pleasure and satisfaction to have been associated so many years with men who have all had such high and honorable ideals. May the superstructure be worthy of the foundation already laid.

"'MALGAMATIN'"

[From MINING AND SCIENTIFIC PRESS, Sept. 24, 1904.]

'Malgamatin' on the pans
  Down the Golden Mile,
Mixers belchin' boilin' sands
  Swellin' someone's pile.
Heat and dust and KCy,
Hot mud splashin' in your eye,
  Twenty pans rotatin';
Spin, you whirlin' devils, spin!
Can't hear nothin' for the din,
  'Malgamatin'!

Now the elevator's stuck,
  Twisted buckets jammed;
Never saw such purple luck,
  May the job be d—d!
For this flamin' dust is chokin',
Might as well in hell be stokin',
  "Bash those edges straight in!"
"Pass, oh pass the hammer here!"
'Taint all counter lunch and beer
  'Malgamatin'!

Chippin' mudflake off the edge,
  Hammer-head went plump!
Close up three-pound weight of sledge,
  Hear the muller bump!
Snatch the clutches out of gear!
Blazes! won't the foreman rear!
  Here's a lovely ratin'!
(Can't he give it to a bloke!*)
Bet a quid† there's somethin' broke.
  'Malgamatin'!

Boss says, "Clean up, Number Four!
  Get the tackle to her;
Lift the muller from the floor,
  Guess we'll have to shoe her!
Jam the bars beneath the dies,
Put some weight on, up they rise,
  Set those cogs gyratin'."
Pans on either side a-steamin'!
Lord! it ain't no place for dreamin',
  'Malgamatin'!

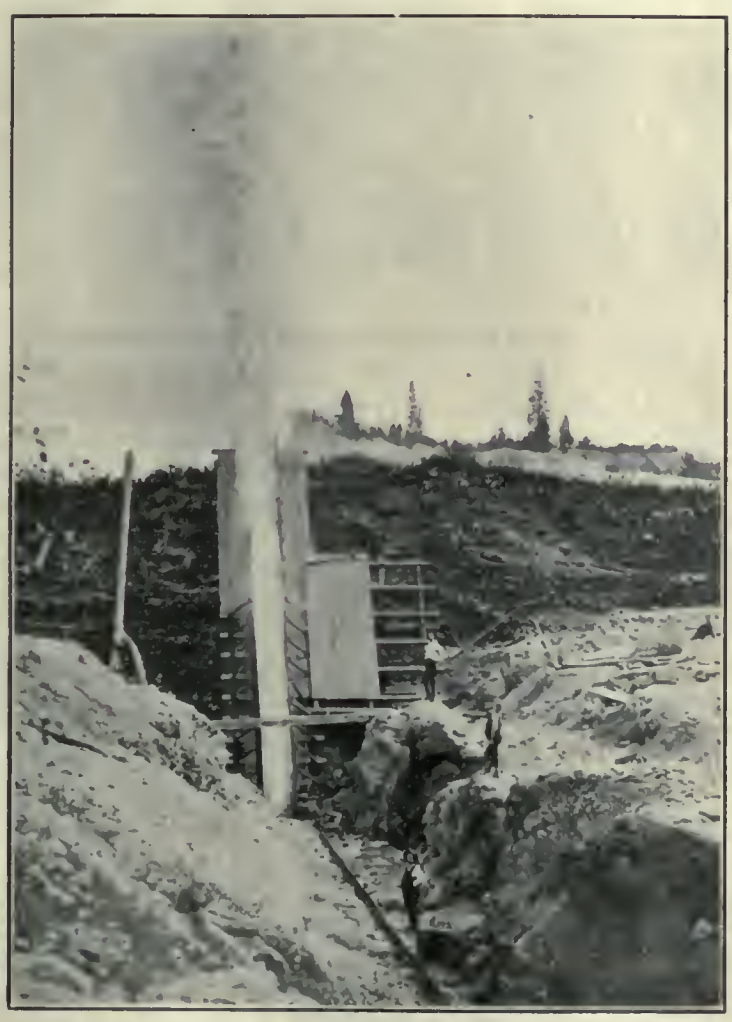
Lyin' thick between the dies,
  Cloggin' up the pan,
Don't it tempt a fellow's eyes,
  Man is only—man!
Half a hundred weight in this,
Ounce or two they'd never miss—
  Go to blazes, Satan!
While my girl's in me believin',
Haven't got no time for thievin',
  'Malgamatin'!

* Slang for 'one of the common herd.'
† Slang for £1.

Hydraulicking in California

Written for the MINING AND SCIENTIFIC PRESS
By H. P. GORDON

The history of hydraulic mining in California is most interesting, though little is known today outside of a few counties as to its present condition. The evolution of the art of mining auriferous gravels in California is the story of a beginning with the gold-pan, progress followed step by step to the rocker, the long-tom, the sluice-box, that terrible engine of destruction, the hydraulic giant, ending with the wonderful mechanism of the modern dredge.



Gravel Elevator, North Bloomfield, California, 1893-94.

Hydraulic mining began in California in 1852; it developed because the rich surface deposits were becoming exhausted. Up to 1883 the gravels of California had produced $1,050,000,000 (see A. J. Bowie's work on hydraulic mining, page 283). About this time the anti-débris law caused all the hydraulic mines to suspend operation except in the northern counties, and it was not until the Caminette law went into effect that hydraulicking was allowed to resume, and then only by mines that were so situated that they could impound their tailing or débris with restraining-dams of brush or masonry, and at present no brush or log dams are allowed, nothing but concrete or masonry being sanctioned, and very few mines are rich enough to afford such constructions.

Before the anti-débris agitation I had worked in hydraulic mines in Montana, and in Eldorado, Amador, and Calaveras counties, California, when the industry was at its best and booming; later I worked in Trinity, Del Norte, Nevada, and other counties of the State, and also in Alaska and in foreign countries. Mines in those days were not known simply as hydraulic mines; they had such names as Henry's Diggings, Slag Gulch, Indian Diggings, Fiddle Town, and Whisky Hill, the latter supposed to be at or near the place pictured by Bret Harte in his story 'The Luck of Roaring Camp.'

The hydraulic miners were the happiest in the State, and little did they dream that the iron hand of the law would soon crush them. When the blow fell, delivered by Judge Sawyer, hundreds of hydraulic miners entered into quartz and drift mining.

In 1893 I became foreman of the North Bloomfield gravel mine in Nevada county, which had been made famous as the mine against which the Anti-Débris Association had waged its bitterest warfare, and for over a year it was subjected to the closest espionage on the part of the anti-débris people. I have no doubt that there was a great deal of graft in that warfare, but that is all a thing of the past.

Echo Hydraulic Mine, Murphys, California.

At the present time hydraulic mines are not allowed to run tailing or débris into the rivers, so it is necessary to use elevators and to impound the tailing in some worked-out portion of the mine. The first elevator in use at this mine, which was previous

to 1893, was of the same style as the modern enclosed elevator of today, but the size of boulder that it could handle was limited to less than 15 in., the size of the throat. Later, the company used an open wooden elevator, which was nothing more than three or four sluice-boxes set on an angle of about 50°; the lower 8 ft. was lined on the bottom with manganese steel plates 2 in. thick, and above that were ordinary wooden riffle-blocks 13 in. thick. The lower sides were lined with boiler-plate iron and partly worn steel plates. Streams from ordinary hydraulic giants were used, the nozzles being set 2 in. from the bottom and on a line with the elevator, yet the friction was so great that the steel plates lasted only a month when running one shift per day. Above the 8 ft. of plates there was no friction to speak of, the wooden blocks lasting longer than in the regular mine-sluices.

I suppose more experiments have been made at this mine than at any other in the State; it was here that the idea of the deflecting nozzle first originated, and as usual in such cases, the men who evolved it never derived due credit or benefit in consequence. William H. Radford, who was manager, and a very progressive man, allowed me to experiment on the wooden elevator, with the result that between us we evolved the open steel-elevator, a view of which accompanies this article. It is an open trough, 4 ft. wide, and about 4 ft. deep, made of ¼-in. rolled steel plates, furnished by the Joshua Hendy Iron Works of San Francisco. The bottom corners are rounded, with a 20-in. board on the upper sides, set at an angle of 52°. The nozzles, 3½ in. diam., are set back 7 in. from the bottom of the elevator, this doing away with injurious friction. In experimenting with the wooden elevator, it was found that if the grade were varied 1° it would work 'heavy'; with 2° it would not work at all, that is, if given less pitch it would drag too heavy on the bottom, and with more grade, it would not fill, the water falling back and choking it. This is important to know, otherwise users will have trouble with this kind of elevator. There was 540-ft. water pressure through a pipe-line a mile long. I think the effective head was a little over 250 ft., but am not sure. About 1000 to 1200 miner's inches of water was used in the mine for 'piping', and anything that came through the sluices in the shape of boulders, pipe-clay, or stumps, went through the elevator without trouble; in fact it would not choke with any material, except by doubling up the water and sending it down with a rush. The view shows the elevator at a height of 54 ft., which was later increased to about 60. We used to keep a nearly round boulder, 22 in. diam., to send through the elevator for the benefit of visitors. It would be dropped in the sluices near the elevator, and in an instant it was out on the dump, then when the water was turned off would be rolled back ready for another visitor.

At one time this mine had been worked in benches but at this later period it was worked in one bench, and as the banks were just 300 ft. high it was occasionally quite dangerous. It would be a long story to detail the methods evolved for working this great mine; many years of experimenting by different managers, had given the knowledge of how to obtain the best results.

This mine had been operated for 30 years, and was good for 30 more, but the anti-débris law forced it to suspend. There was no room for storing tailing.

In all my experience in gravel mining, including Ecuador, Colombia, Costa Rica, Idaho, Montana, Oregon, and Alaska, I have never yet seen a territory that would compare in the value or extent of its mineral deposits with California, and some day it will be worked. It could be done without injury to the rivers, if the mine owners would form a powerful combination for reclaiming the tule and waste lands along the lower reaches of the river by diverting to them the débris from the mines.

COALINGA OIL DISTRICT, CALIFORNIA

A report on the geology and oil resources of the Coalinga oil district, in the western part of Fresno and Kings counties, California, by Ralph Arnold and Robert Anderson, has been published by the United States Geological Survey as Bulletin 398. The district described, which is about 15 miles wide and 50 long, stretches along the northeast base of the Diablo range and includes a band of productive oil land three miles wide and 13 long at its north end and a narrow strip of oil land along its southwestern boundary. The region includes about 550 producing wells, which range in depth from 600 to 4000 ft. and penetrate from 20 to 200 ft. of oil sand. The product ranges from a black oil of 15° Baumé to a green oil of 35° Baumé. The yield of single wells differs greatly, ranging from 3 to 3000 bbl. per day. The district is the leading producer in California and one of the most productive in the world. Its production in 1907 was 8,871,723 bbl., in 1908 it was 10,386,168, and in 1909, it was probably 15,200,000 or more.

The total quantity of oil thus far taken from the ground in the district to the end of 1909 was about 63,000,000 bbl. of 42 gallons each, leaving available a vast store of oil which has been roughly estimated as 2,737,000,000 bbl. Even if this great quantity of oil is in the ground it is not possible to state whether all of it can ever be obtained.

Pipe-lines connect the district with the seaboard at Monterey, 110 miles away, with San Francisco Bay, 200 miles away, and with other points. The report describes the topography, geology, paleontology, and oil in the Coalinga district, which have been in part described in an earlier report published by the Survey but not now obtainable. The present report includes a more complete discussion of the district and many new maps, sections, and other illustrations, besides a paper by Irving C. Allen on the chemical and physical properties of the oils. Many interesting points in connection with the history of the region in past geologic ages are brought out, and by means of careful descriptions of the formations a foundation is laid both for an accurate study of the occurrence of oil within this region and for the tracing of formations and oil horizons.

Fifty Years of Smelting in the Western States

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN

In the last few years of the decade 1860 to 1870, occurred a great development of the metallurgical works of this country, accompanied by the investment of much capital in mines and reduction works. In this article the development in lead and copper smelting especially, is discussed and comparisons made with present-day practice. Of the two kinds of ores those of lead are easier of treatment than those of copper. In White Pine county, Nevada, in the sixties smelting of pure carbonate ores was effected in little Mexican furnaces built of adobe, remains of which still exist throughout the West. On so small a scale this was too costly and was soon given up. By 1870 some fifty blast-furnaces were engaged in smelting lead-silver ores. In the main the oxidized ores were treated though sulphides were handled to some extent. The ore at Eureka, Nevada, contained arsenates and arsenical pyrite, so that the products of smelting were not only base bullion and slag but some matte and speiss. These by-products, because of the high percentage of lead carried in the charge, were poor and were thrown away. At Argenta, Montana, the base-bullion was cupelled and only the silver shipped, a method followed today in the remote districts of Mexico. Base-bullion in general carried $60 to $500 per ton in gold and silver. At the time silver had its full mint value of $1.2929 per ounce.

The earlier furnaces of the decade were 20 by 30 in., drawn narrower at the top with one or two tuyeres and had a capacity of 6 to 8 tons daily. By 1870 there were improved furnaces of two kinds, the rectangular and the round. Thus, at Eureka, Nevada, by 1870, Arents had put in a furnace 36 by 54 in. with side and end-boshes, and 78 in. square at the feed-floor. It had four tuyeres per side and two at the back, ten in all. A circular furnace 48 in. diam. was also built, 78 in. diam. at the feed-floor provided with 12 tuyeres. Both furnaces had a smelting height of 10 ft. and worked well, but the rectangular furnaces had 20 to 25% greater capacity than the circular one, say 42 tons daily. Today we find no other than the rectangular furnaces up to 45 by 160 in. with ten tuyeres per side and smelting a maximum of 250 to 300 tons daily. By 1870 the principles of slag formation had been clearly set forth and practised, particularly by Eilers, Hahn, and Raht, the so-called half-slag being preferred. It was then thought that for successful smelting the silicious ore should be crushed to about pea-size, though the carbonate lead ore was lumpy. It was feared that the hydrated iron ores would make iron sows. Indeed with the high percentage of fuel considered necessary there was this danger, and it was not until later, when fuel was cut to its lowest limit, that it disappeared. At Ogden, Dunn & Co.'s works, at Eureka, Nevada, litharge was added to a charge low in lead to hold silver from going into the matte. The fuel used was charcoal worth 15 to 34c. per bushel, some 22% of the charge being thought necessary. Coke was considered better, provided the low blast-pressure could be increased. As a matter of fact, when freight rates allowed later, it was brought in and gradually substituted for charcoal. Today it is practically the only fuel. The blowers used were Sturtevant fans and Root blowers. The pressure then carried were 8 to 12 oz. per sq. in., today five times as much is common. Then a so-called No. 8 blower would take care of three furnaces and needed 20 horse-power to run it. Today a single blower delivers 400 cu. ft. per revolution at a pressure of 3 lb. per sq. in., using 550 hp. By 1870 the Arents siphon-tap now in general use was introduced, so that an outside well was in communication with the interior of the furnace. The old way to tap was to stop the blast, open the tap-hole (sometimes a hard job), run the matte, slag, and lead into a kettle set in the ground, stop the hole, and turn on the blast. Sows made often during the stoppage.

Roasting of ores containing galena was recommended. This could be done in stalls and heaps, but roasting in reverberatory furnaces was considered by all means the best. In the West this was early done in small Mexican reverberatories and the product was withdrawn slagged. It is interesting to note how long-bedded hand-operated furnaces have survived despite their expense and the small output. This had been due to the fact that in a mechanical furnace lead-bearing ores, by an accidental increase of temperature over the normal, may unexpectedly agglomerate and stop the operation of the mechanical stirrers. For lead-free ores, such as copper sulphides, mechanical furnaces have been an unqualified success. Reverberatory roasting formerly cost $4 per ton; today it costs $1.75. Mechanical roasters operating on self-roasting ores cost no more than 25 or 30c. per ton. By 1870 the water-jacket was only just about to come into use; the water-cooled tuyere was, however, used. After the jacket came in, the water-cooled tuyere was retained and used for ten years, but was finally abandoned. Today the cast-iron jacket is still to be found, but in copper smelting practice has been given up in favor of steel jackets. These can be of any desired size to 6 ft. wide by 10 to 12 ft. high. They are built so that no rivet heads are exposed to the fire. Today it is possible to handle even these large jackets with ease.

Blowing in was then a serious business and fuel was freely used. The furnace was filled to the throat with charcoal and this was set blazing. Lead was added in sufficient quantity to fill the crucible, followed by slag charges and finally ore. Today the lead is melted in the crucible. Then wood is added to the bosh followed by coke, slag, and ore. Fire is then set at the tuyeres and the blast gradually applied. In such case the presence of appreciable overfire may be noted and the consequent loss of lead by volatilization. In the early times no forehearth was used; the small amount of matte made was low in silver and was thrown away. The furnace was stopped and the hearth cleared out every 8 hours, while campaigns lasted three to six weeks. When accretions in the shaft became excessive the furnace was run down,

blown out, and in about a week was again ready for use. Today a furnace is expected to run for months. When accretions form they are cut off and the furnace is again running in 24 hours.

In the sixties inside men worked 8-hour shifts. Ten to twenty years later the time was increased to 12 hours. Today the 8-hour system has been resumed. The cost of production per ton of ore was $39 with 25% lead in the charge. This included freight by way of San Francisco to New York and expense of refining ($35 per ton of base-bullion). Examples of slag were:

	SiO_2	FeO	Pb	Al_2O_3	CaO
I (thin)	26.12	5.2	2.79	5.8	12.0
II (thick)	37.50	50.7	8.00	—	2.8
III	30.20	50.6	8.70	3.0	7.1

Today in Utah where it pays best to run silicious slags, the silica has been increased to 37 or 40%. For more rapid driving the type of slag, called 'three-quarters', is considered best. The recovery in silver and gold was 93%, today there is a plus recovery of gold and 97.5% of the silver; even more when the modern bag-house is used. The lead in the slags instead of going to the above-named figures is now under one per cent.

In Colorado the first works, those of James E. Lyon & Co., were ill arranged and poorly managed. In 1866 smelting for copper matte was practised and some 80 to 100 tons produced. The furnaces were later torn down and upward of 100 tons of rich matte found which had leaked into the foundation. N. P. Hill's works, a short distance below them at Black Hawk, were built by 1868, and were carefully managed. Reverberatory smelting was practised and the copper matte produced was shipped to Swansea, England, for final treatment. The copper in it paid the cost of freight and treatment and the profits came from the gold and silver. The difficulty at this time was that there was not a steady supply. For gold 20 to 50% of its value was paid, also 75c. per oz. for the silver; copper was bought at $2 per unit. In operating, the smelting reverberatories took a charge of two tons every 8 or 10 hours; say 5 to 6 tons daily. Today our largest reverberatories, 19 by 114 ft. in size, smelt 250 to 300 tons daily, and mining is done on so large a scale that at the Washoe works, Anaconda, besides the blast-furnaces, eight reverberatories are steadily operated. While at that time the matte was shipped away, now it is brought to the stage of blister copper on the spot, and this is sent to near its marketing point (New York or Baltimore) for electrolytic refining.

In California the showy oxidized ores of copper were in evidence particularly in the vicinity of Copperopolis, Calaveras county, while in lesser degree sulphides were to be found. Most of such ore, going from 8 to 15% copper, was shipped to Swansea. Some blast-furnace smelting was attempted, but the furnaces were so small, fuel so expensive, and campaigns were so short that it did not pay, and by 1870 practically nothing was being done. In blast-furnace work, Haskell overcame the troubles incident to burning out at the bosh by the use of water-jackets. He used pine charcoal costing $70 to $80 per ton, smelting 12% copper ore with a consumption of one ton coal to 8 of charge. Much of the impure blister of 80 to 96% copper contained $50 in gold per ton. The works at the Union mine, Copperopolis, had two blast-furnaces and four kilns for roasting. The two furnaces needed a 20-hp. engine to produce the blast necessary and each had a capacity of 8 tons in 24 hours. They obtained from ore averaging 8% copper a matte of from 40 to 80%, and containing $200 to $250 in silver and gold per ton. We may compare this with the practice of today where blast-furnaces with 4 by 22-ft. hearth dimensions put through 500 to 600 tons daily, or where the 4½ by 86-ft. furnace at Anaconda has a capacity of 2800 tons in 24 hours. The smelting of oxidized copper ores to produce blister copper in one operation has been kept up to within recent years. The difficulty has always been to obtain a clean slag, since with every care the average of the slag was 2 to 3% in copper, which, on low-grade ores, was prohibitive. At Price's works, Antioch, near Mount Diablo, Contra Costa county, California, in 1862 a reverberatory furnace of 8 tons capacity, 13 ft. 6 in. long by 6 ft. 4 in. wide, with a 65-ft. stack, was built to produce a matte of 50% copper. The furnace was run some time, using local coal, and had to be shut down for re-lining once in 15 days. The interest on money in California was then 18 to 24%, and hence the undertaking was not a financial success. The Selby lead smelting works was established at North Beach, San Francisco, in 1867. Besides these ventures in Colorado and California some attempts at smelting copper ores were made at Peavine, Nevada, at Rockland, in southwestern Oregon, and at Williams Fort, in Arizona. At the latter place the Great Central Mining Co. had works which turned out an 80% copper matte.

In those days the energies of the metallurgist were devoted to obtaining a product of base-bullion, of matte, or of black copper, expecting to ship it away for refining. He took no pains to effect a close saving in the slags or in the flue-dust. This was left to a later period. He was content to waste one fortune over the dump and a second in the air provided he could obtain a third to put into his pocket. The small capacity of his furnaces, his short campaigns, and the high price for labor and interest on money were against him. Also his ore-supply was small and uncertain and delays of various kinds ate up profits. Today furnaces are large, and with regular supplies of ore, can make long campaigns. Labor is assisted by mechanical appliances. One of the greatest aids to modern smelting operations is that the railroad reaches into the mining district, and it is possible to assemble fluxes, fuel, and supplies, and with abundant capital to carry them, so as to bridge over periods of unexpected delays due to washouts and labor strikes. Yet with all these advantages with the best of business and technical skill it is hard to bring and keep smelting works up to their full capacity.

Railroad to Denver.—The Omaha Pacific Railroad Company have notified the Government that they intend to construct a railroad from Denver to the main road, a distance of 102 miles, and have it completed. October next.—Mining and Scientific Press, March 21, 1868.

Keystone Consolidated Mine and Its Early History

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM H. STORMS

The mining annals of the West contain no more interesting and romantic story than that giving the history of the Keystone Consolidated mine at Amador City, California. One of the claims included was the scene of the commencement of quartz mining in Amador county, it being at the Spring Hill mine, early known as 'The Ministers' Claim,' that the original discovery of gold-bearing quartz on the Mother Lode in Amador was made. This was in 1851. The first mill built at this mine was not at once the success that had been anticipated for it. Arrastres were built, after the Mexican fashion, at some neighboring mines and considerable gold obtained. The arrastre, though undoubtedly a famous gold-saver, is nevertheless a device of extremely low efficiency, and although the selected ore generally crushed in the crude mills at that time contained about $100 per ton, the process was slow and not at all in keeping with the energetic spirit of those strenuous days; consequently, the arrastre as a metallurgical device was soon abandoned on the Mother Lode.

Although the early outlook for the quartz mines was promising, expenses multiplied in an unexpected manner when underground mining had progressed somewhat. Heavy swelling ground was encountered in the fissures and became the cause of so much trouble and expense that in a number of cases the attempt to work the ground was abandoned as hopeless. The owners of some of the mines, like Hayward and Chamberlain at the Eureka, became involved in debt, which, together with the numerous other troubles mechanical and metallurgical, resulted in closing not a few mines for a time. It is related that at one time the management of the Spring Hill mine purchased a quantity of hay from a rancher near Campo Seco, and the company failing for a long time to pay this account, the rancher employed the sheriff to watch the mill and seize the amalgam at clean-up time. The superintendent, hearing of the presence of the sheriff in the vicinity, suspected a coup of some sort, and took the amalgam down into the mine and hid it. The sheriff, not in the least disconcerted by this trick, went below to search for the hidden amalgam. The superintendent thereupon stopped the pump with a view to flooding the mine workings, and saving his clean-up, but the sheriff was too quick for him and soon appeared at the collar of the shaft with the amalgam.

In 1857, the Spring Hill was consolidated with the Granite State and Walnut Hill, which latter had previously been consolidated as the Keystone, and the combination was then known as the Consolidated Keystone mine. The several properties included in this consolidation were heavily in debt, and a mortgage had been given on the property, which mortgage was foreclosed, but a prior judgment in favor of A. H. Rose and Philip Crusart took precedence, Rose eventually becoming sole owner of the property, which at that time was as unpromising an aggregation of mining ground as could be found along the Mother Lode. However, it was worked in a desultory manner, the mill being at times employed on custom ore, whenever any was obtainable. The shipments of bullion thus made reached many thousands of dollars. So, with many vicissitudes, the Keystone mine continued its unhappy existence.

Amador City and the Keystone Mine. From an Old Photograph.

On September 5, 1865, A. H. Rose sold the Consolidated mines to J. W. Gashweiler, John Henning, and H. N. A. Mason for the sum of $108,000. In December following this transaction, these men transferred the property to James McDonald, Andrew B. McCreary, and others. The consideration paid in this transaction I have been unable to learn, but the price, both in this transaction and the previous one, was considered exorbitant and entirely out of proportion to the actual value of the property. Mr. Rose was evidently well satisfied with his sale of the property, and presumably Gashweiler and his associates were equally glad to get rid of so 'bad a bargain'. It was commonly said that the returns on custom ores had been used by Mr. Rose in effecting the transfer to Mr. Gashweiler and his partners, though no such accusation was made in relation to the subsequent transfer. Mr. Rose, it is reported, was heard to say, "No child now living (1865) will ever live to see the Keystone mine a profitable enterprise."

Up to the time of the transfer of the property to

Messrs. McDonald and McCreary, but one vein had been worked. Some of the miners conceived the idea that there must be another and, perhaps, better vein back of the hanging wall. Accordingly a cross-cut was started easterly and at the first round broke into a vein actually bespangled with gold. Within the first month from the time of this discovery, over $40,000 was produced by the little Keystone mill. Month after month, this rate of output was maintained, until the Keystone mine came to be recognized as one of the most valuable gold mines in the world—one which could always be depended upon to yield monthly a large amount of gold at a handsome profit. The mine continued its heavy output of gold year after year until its production reached far into the millions. From official data the aggregate output to the present time is known to approximate $17,000,000.

When the Keystone workings broke into bonanza early in 1866, A. H. Rose, who had disposed of the property the September previous, was filled with great regret. After thinking the matter over for nearly three years, he finally evolved a remarkable plan by means of which he hoped to recover the property for practically nothing. There are few men who would dream of employing such a method as he devised to regain possession of property legally sold to honest men, and fewer still who would have the nerve to put such a scheme to the test. Mr. Rose had plenty of nerve and went about the execution of his plan without delay and apparently without fear of either failure, or of the consequences of detection. He contemplated nothing less than bribing a United States Deputy Mineral Surveyor to return a falsified plat of survey to the land office at San Francisco. Prior to the land survey, the land holders—mineral claimants as well as owners of agricultural lands—had no accurate knowledge of where their property would be found to be situated when the land survey had been completed. Rough surveys had been made, probably based on doubtful starting points, and it was commonly supposed that the Keystone Consolidated mines, the Original Amador, the Bunker Hill mines, and Amador townsite, were on the west half of Sec. 36. Mr. Rose owned a tract of agricultural land just east of Amador City and the Keystone mine, which tract was supposed to be on the east half of Sec. 36. When the survey was made in 1869, J. G. Mather, government surveyor, returned a plat to the land office at San Francisco, showing the mines to be situated, as had been supposed, on the west half and the Rose ranch on the east half of the section. Every section of Government land numbered 16 and 36 had been donated by the United States to the State, for the benefit of education, and such sections were known everywhere as 'school lands', and were usually sold as promptly as possible. No one thought strange of it, then, when application for a patent to the east half of Sec. 36 was made by H. Casey, A. H. Rose, acting as his agent. The patent was issued by the State and Mr. Casey promptly disappeared. Mr. Rose then came forward presenting deeds for his tract of land from the State of California, to the east half of Sec. 36, on which the Keystone and adjacent mines were really situated, and demanded possession of the mining property. Henry Casey had bought the east half of Sec. 36 for $400, and Mr. Rose now claimed not only the Keystone Consolidated mines, but the Original Amador, and Bunker Hill mines, and the townsite of Amador City as well. It is needless to say the demands of Mr. Rose were promptly refused and a new survey was made, which demonstrated the interesting fact that the mines and townsite were situated on the east half of Sec. 36 and that Mr. Rose's vineyard was on the west half of Sec. 31, adjoining. He insisted that as he had received a patent from the State of California for the east half of Sec. 36, he should be placed in possession. Fraud was clearly shown and his petition denied. He still fought desperately, and at great expense maintained a lobby at Washington and brought every possible pressure, political and otherwise, to bear on the Secretary of the Interior, but without avail.

The Keystone mine continued to develop year by year. The expense of mining and milling in those early days was much greater than now, accordingly only high-grade ore was extracted; the low-grade being left in the mine for those who came later, as has been done for a century or more in mines elsewhere. Had the ground been hard, this would not have been so bad, but it is not, and as a result, miles of the old workings of the Keystone property are now inaccessible and have been in that condition for years.

The Keystone mine, like most other great mines, is not without its tragedies. One of these occurred over 30 years ago. A large clean-up had been made and the amalgam placed in the retort in a brick building near the mill. For several hours, the fires were kept up vigorously and the quicksilver had been distilled, leaving a sponge of gold worth over $50,000 in the retort. For some reason, the superintendent decided to leave the gold in the retort until morning, placing a watchman in charge. A plot had been formed by a number of Austrians, to rob the retort, the presence of the watchman evidently giving them small concern. They first attempted to suffocate the watchman by means of chloroform, boring a small hole through the window frame for the purpose of introducing the drug, but it failed to have the desired effect. One or more of the men then boldly entered the retort room and quickly overcame the surprised watchman, preventing him from making any outcry by striking him on the head with a hammer. The blows rendered the unfortunate man unconscious and his death resulted in a few hours. When the watchman had been silenced, the murderers and would-be thieves turned their attention to the retort. Upon opening the outer iron door, they found the retort still very hot and were unable to remove the heavy cast-iron cover of the retort, not understanding how the key should be removed to release the cover. Failing in these efforts, the men became frightened and fled. Their crime was quickly discovered and pursuit commenced. In a short time several were captured and others killed by the posse sent out to apprehend them.

The Washoe Process

Written for the MINING AND SCIENTIFIC PRESS
By A. D. HODGES, Jr.

You, Mr. Editor, have asked me to describe the parentage, development, and metallurgical and mechanical limitations of the Washoe process. You have given me a task which deserves a volume. And you beg me to be brief. Under the circumstances the best I can do is to rehearse concisely certain facts, and let you draw what conclusions you can.

The father of the process was that energetic, enthusiastic, and capable millman, Almarin B. Paul. He was the first to conceive and carry out the idea of treating the sulphuretted auriferous silver ores of the Comstock with the chemicals of the patio process in the pans which he had used in the gold mills of California. His project was received with general distrust, but he perservered, and on August 11, 1860, his Pioneer mill began successful work in Washoe. Paul's mill, constructed in San Francisco, hauled over the mountains and set up in Gold Canyon, all in the space of two months, was necessarily imperfect; but its success led to the erection of a host of others. These were built by the able mechanics of San Francisco and Washoe. The problem submitted to these men was to construct machines which would treat the ores economically and rapidly and extract an amount of the precious metals sufficient to pay dividends. They solved this problem well. But as the millmen were unversed in chemistry and never were allowed to know what percentages of gold and silver was extracted in their mills, the first development of the Washoe process of necessity was purely mechanical.

Interior of California Pan Mill.

Let me here mention that during my active experience in Nevada, I knew of only two silver mills treating unroasted ores in that State, which checked their work by proper weighings and assays and knew exactly what they were doing.

Louis Janin was living on the Comstock, and with him were associated his brothers Henry and Alexis, all of them educated mining engineers. They were the next persons to develop the process, which had halted with the rich ores holding simple sulphides. Investigating the chemical side of the question, they discovered that, by the rational use of certain reagents, the poor ores and the tailing (slime and sand), which held multiple sulphides, could be worked profitably. Henry Janin took out a patent for the use of dichloride of copper, but nothing was ever done with his process; for the employment, in proper amounts and proportions, of salt and bluestone was found satisfactory. Louis Janin purchased and ran with pecuniary success the Dayton Reservoir mill so long as he could obtain tailing to work.

The Lyon mill at Dayton copied Janin's methods and improved them. This mill had an excellent superintendent, George Langtry, who was a fine millwright. It also had an assayer who was in charge of the sulphuric acid, the bluestone, and the bullion departments. Careful tests on a working scale were constantly made. The pans and settlers were perfected. The process was watched with loving vigilance and modified whenever, and as soon as, a change was found desirable. Observers were fond of saying that the Lyon mill never ran the same for two consecutive days. This of course was an exaggeration, but it illustrates the close watch kept over operations.

The Lyon mill, in the period from 1873 to 1877, treated sand and slime holding from 3 to 20 oz. of silver and 0.05 to 0.25 oz. of gold per ton, and extracted in the shape of bullion 70 to 85% of the precious content, and paid continuous dividends. The percentage of gold obtained varied from 25 (in the poorest grades) to 60 (in the better material); that of silver, from about 80 to nearly 90. The variable extraction percentage of the gold *seemed* to be due chiefly to the varying nature, amount, and gold-content of the iron sulphides whose behavior was erratic. Many thousands of tons, averaging about 0.055 oz. gold and 2.8 oz. silver, were worked at a profit of about 75c. per ton paid in dividends. The tailing escaping from the mill held about 0.036 oz. gold, less than one-half ounce silver, and a negligible amount of quicksilver.

The liberal use of chemicals resulted in a very base bullion which, at this mill, contained on the average about 85% of copper. No one had ever succeeded in refining such material (which could be sold only at a very heavy discount) until the assayer of the Lyon mill devised a cheap and easy process,* whereby the copper was recovered in the useful shape of sulphate, and fine silver and fine dorée bars were produced, while the losses in refining were so small as to be imperceptible. This completed the development of the Washoe process on the Comstock Lode, so far as known to me.

About 1870 Alexis Janin went to the Meadow Valley mill in Pioche where he was associated with, and later succeeded by, Gardner F. Williams who was afterward the brilliant manager of the famous Kimberley diamond mines. Janin and Williams introduced the Washoe process at Pioche, modifying

*Described in the Trans. of the Amer. Inst. Min. Eng., XIV:731.

it to suit local conditions, and ran it for years with great success although the ore contained noteworthy amounts of lead and other troublesome constituents. Mr. Janin published an interesting and instructive article which appeared, if my memory serves, in one of the reports of the United States Commissioner of Mining Statistics.

In 1886 mill tests of the Washoe process were made at Cerro de Pasco, Peru, in a broken-down mill, on *cascajo* ores holding from 12 to 18 oz. silver. The exact mineral composition of these ores—an ever varying composition—has never been determined. But here is an analysis which is fairly representative of a very large class:

	Per cent.
Silica	73.00
Alumina	6.50
Iron peroxide	13.50
Iron protoxide	0.50
Iron pyrite	2.00
Lead carbonate	1.25
Copper	0.05
Zinc	0.50
Silver	0.042
Antimony	0.37
Arsenic	0.03
Manganese peroxide	0.70
Lime and magnesia carbonates	1.50
	99.942

Gold occurs in mere traces. Thallium has been detected in some ores.

Tests for the condition of the silver have given diverse results. Charles A. Stetefeldt, to whom large amounts were submitted for lixiviation experiments, found 25 to 30% as chloride, about 20% in the native state, a slight amount in undecomposed pyrite and in lead carbonate, and the remainder in an unknown combination. The numerous tests made at the Cerro on samples representing thousands of tons indicate 50 to 60% in a metallic condition and as a chloride, the rest held in combination with sulphides, antimonides, arsenides, and lead carbonate in ever varying proportions. The ores tested in the mill yielded, with mercury alone, in fine bullion, 50 to 60% of the silver, equalling the results of the patio process. With the addition of salt and bluestone, such ores as the one whose analysis is given yielded 85%, but the bullion was very base.

To me amalgamation is the most fascinating of all metallurgical processes. It is neat and clean and speedy in its returns and full of alluring mysteries. It was my dream for years to have a large mill with a well equipped laboratory wherein the constantly occurring problems could be investigated. Perhaps if the Comstock merger be effected, my dream may be realized for somebody else. Until then I know not how the question of the possibilities and limitations of the Washoe process can be settled.

The metallurgical works of San Francisco have always formed a prominent feature of our local home industry. The recent addition of argentiferous ore to the auriferous, has opened a new and profitable field, which has lately been occupied by the Ophir Works, situated at the foot of Taylor street, North Beach.—June 30, 1860.

PRIMITIVE MINING

We reproduce below from one of the early issues of the MINING AND SCIENTIFIC PRESS, a wood cut illustrating methods of mining in California in the days when the industry was young. The two part-

ners, with only pick, shovel, and pan, are typical of the men who laid deep the foundations of American mining. Such pictures help to make clear how much early mining depended on muscle.

The pioneer ship of a Japanese coal fleet has arrived at this port from Kuchinotzu. She is the British ship Aigburth, and made the passage in the smart time of 33 days. Other vessels, coal-laden and consigned to E. C. Evans, agent for the Japan mines, and on the way, are the American schooner Puritan, the American bark Mt. Washington and the British ships Bandaneira and Lord Downshire. Some of the coal is in pressed bricks, but the most of it is destined to enter into competition with the cheaper grades of coal prevailing here.—December 16, 1893.

Concentrates Re-concentrated*

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

It is believed that the present (April, 1896) number of stamps in operation in this State aggregates a little over 4,000.

Salt cake is a commercial name given to crude sodium sulphate, and is an intermediate product in the manufacture of sodium carbonate from sodium chloride. It is employed in glass making.

When drilling in sandstone the drill-bit should be tapered somewhat and then flattened instead of drawn to a cutting edge. If a chisel-bit is used in drilling sandstone the bit will wear very sharp, and the hole will frequently become fitchered.

All borax contains more or less water of crystallization. Borax glass used in assaying is the borax which has been heated until the water is driven out. If the crude borax is introduced with the charge in a crucible it is likely to cause the charge to boil over, thus destroying the accuracy and value of the assay.

Where A owns a patented placer claim, B cannot go upon it and locate water, no matter how long disused. If a water right was at one time taken up on A's claim, and the water has not been used at the point to which it was originally taken or elsewhere, the water may be re-located at some point below or above A's claim under the laws governing the relocation of water rights.

It is held in California and Nevada that if one abandons tailing from his mine or works and it flows down stream and becomes deposited on the lands of another, it belongs to that other, and if tailing accumulates on unappropriated public land it has been the custom to recognize the right of the first comer to appropriate it by proceedings analogous to the location of placer claims.

In 'rawhiding' ore in British Columbia cowhides are used just as taken from the carcass; inch holes are cut one foot apart around the edges, the hide laid flat and the ore piled in sacks thereon; the ends and sides are drawn together by a rope passed through the holes, the neck in front, and fastened to a singletree. A mule is the motive power, and fast time is made down the trail, a rough lock, consisting of a log chain, being used in steep places.

The call for the International Gold Convention, to be held in Denver in July, has been received. It is stated that the objects are to secure such national legislation as may be calculated to promote the business interests and development of the resources of the mining industry in North and South America; to bring together mining men and investors; to increase reciprocal trade among them; to discuss such questions as are naturally suggested by its objects; to cultivate acquaintance, fraternal feeling and hearty co-operation among the various mining, commercial and labor bodies represented; and especially to take under advisement the importance of the creation by Congress of a department to be known as the Department of Mines and Mining, thus securing a Cabinet officer who represents an interest which affects more than one-third of the people of the United States.

Ground mica is used in some quantity in making the coarser grades in mica bronzes and paints and also as an absorbent for explosives. Ground mica also forms an ingredient in some heavy lubricants. The finest ground mica or mica flour finds a considerable market with the manufacturers of high-grade wall papers, the lustre obtained by the use of the muscovite dust having the advantage of both permanency and brilliancy.

It is the aim of Concentrates to answer questions relative to the economies of mining and metallurgy and cognate sciences, to mining law, and questions concerning geology and mineralogy. All questions should be clear as possible, that it may be known what is wanted. Questions cannot always be answered in the issue following their receipt, as it is sometimes necessary to wait some time to secure an answer, and also because other questions previously received take precedence.

The best gold story of the week comes from Utah, where, a telegraphic legend asserts, a young school teacher and his pupils, while engaged in geologic research, found gold galore in the San Juan river. The regular 'three old California miners' were on hand to take charge, and the result of the first day's work in the bed of the stream yielded $2300. The next best comes from the Pichaco district, a long letter stating that "white gold" has been found there which "sells readily for $24 an ounce."

Civilization is rapidly advancing in the Yukon region, Alaska. Forty-Mile City is the largest camp and contains 98 buildings, including miners' cabins, two large stores, one music hall, five saloons, one billiard parlor, one tin shop, two blacksmith shops, two assay offices, a mission church and one shoemaker. Provisions of all descriptions and clothing are sold at very reasonable prices. Canadian rye, British Columbia rum and high-pressure brandy are selling at the reduced rates of four bits a glass, $8 a bottle, or $36 a gallon. This reduction is owing to the large quantities now in transit to Forty-Mile creek.—June 9, 1894.

In chlorination, lead in the ore occasions an extra consumption of chlorine, though, of course, a heavy galena percentage in gold ore concentrate usually indicates considerable accompanying silver, which in chlorination, is not wholly satisfactory. Unless a chloridized roast is used, lead, even in considerable quantity, does not materially affect the fineness of the precipitate, but the addition of even a small amount of salt to the roasting ore converts large quantities of lead into chloride, which, being dissolved and finding its way into the gold tanks, is there thrown down as sulphate, to the great deterioration of the gold precipitate, the result being a very base bar.

Ancient Correspondence

Letters from special correspondents giving the news of days gone by. From the files of the MINING AND SCIENTIFIC PRESS.

GRASS VALLEY, CALIFORNIA

Pike Flat. — Boston Ravine. — Massachusetts Hill. — Gold Hill Mill.—Eldorado County News.

I have walked through and around this pleasantest of mountain towns, and find every evidence of substantial and enduring prosperity around on every side. In the town itself numerous brick buildings—stores and dwellings—are going up, while in the outskirts I saw many pretty cottages in process of erection. This is by all odds the liveliest and most agreeable of all interior towns that I have visited—its people are genial and hospitable—its society is good—its climate salubrious—its soil is wealthy in agricultural as well as mineral productions—its aspect inviting in nearly every respect. As I stood on the ridge-road leading to Nevada, to-day, I could not help sorrowing that Pike Flat, which lay stretched out to the left of the town, should have been so torn up. Once the glittering gold lay buried beneath its verdant bosom, (hence named Grass Valley), but the ruthless pick and shovel have disemboweled it and Pike Flat looks like the skeleton of its former self. But for the

Sutter's Mill, Where Gold Was Discovered in California.

bare "bed rock," heaps of boulders, and gaping holes about Grass Valley, it would indeed seem like an enchanted spot. The mines here are, on an average, paying well, with prospects of doing better. I have been down to Boston Ravine and on Massachusetts Hill—a mere flying visit though. On my way I visited the Gold Hill Mill and ascertained that it is working with its usual success. The Massachusetts Quartz Mill works steadily along—the lode continuing to pay as well if not better than heretofore. In the latter are employed 130 men. The Mill reduces from 125 to 150 tons of quartzose rock per week. From 2500 tons of rock recently crushed, nearly $20,000 worth of gold was extracted and sent to San Francisco—an average, you see, of $80 to the ton.—July 6, 1861.

We have been permitted to examine a few specimens of ore from the Blue lead at Spanish Flat. This ledge is owned by Varozza, Wilmer and others. Edwards and Pasqui have a contract to sink a shaft on the ledge from the old tunnel. They are now down about 50 feet, where they have a ledge from 5½ to 6 feet wide. Assays of the ore has ranged from $80 to $100 per ton. There are now about 100 tons of ore on the dump. The samples exhibited to us sustain the above reports as to the quality of ore. Under the superintendence of Dan C. Wickham the Church Union mine three miles northwest of El Dorado is developing into a splendid property.—July 22, 1876.

QUINCY, CALIFORNIA

Light's Canon.—American Valley.

Returning from a trip to Honey Lake Valley, I called at the copper mines in Light's Cañon, and spent two days among the different mines. The Superior mine is opening very fair; it is destined to be one of the very best mines in the State, though the Eclipse ledge is undoubtedly the great parent vein of that district, and will in a very short time eclipse all other veins in that section. They are going ahead with their work with a spirit truly commendable. There are the Superior, Summit, Northern and Southern Superior, Eclipse, Lincoln, Mammoth, and four or five others, that are worked with energy, which probably will be shipping ore within a few months. The Superior has about $5,000 of first class shipping ore on hand, besides having wasted more than one-half that amount in the last three months time. The mine can be greatly improved, I think, by different management. The other ledges it is understood, are to be worked in a different manner, but let that be as it may, that section of our State is bound to speak for itself in a very short time, for there never has been as good copper mines discovered in the United States before. I am now spending a few days in the Argentine district, near American Valley, Plumas county, and I find that the Howard Silver Co. have struck it very rich in their tunnel. They are about 200 feet below the surface, and have gone into the vein ten feet, finding the rock completely mixed with sulphurets of silver. I have just made an assay of one pound of the rock, and I find it pays at the rate of $408 per ton, of 2,000 lbs. It was no picked rock, but a fair average of the rock for the ten feet in the vein. They are still at work cutting the vein to find how thick it is; then they intend to call a meeting to take measures to put a mill on the ledge, and I think I am safe in saying that they undoubtedly have a good and rich silver ledge.—June 4, 1864.

BAKERSFIELD, CALIFORNIA

Asphaltum Production. — Sunset Fields. —New Oil Discoveries.

Out in the foothills of the Coast Range of mountains, about 35 miles to the south and west of Bakersfield, lie some of the most interesting resources of Kern county, which are now being rapidly developed, and which have recently drawn a great deal of attention to Kern county. Here are the Sunset and Buena Vista oil fields. For a generation or more they have attracted the attention of capitalists, and company after company has been formed only to abandon the field after unsuccessful attempts to reach the precious oils to which surface indication pointed, and often with the fruitless expenditure of many thousands of dollars. In spite of these failures, two enterprising citizens of Bakersfield—Solomon Jewett, president of the Kern Valley Bank, and H. A. Blodget, cashier of that institution—had an abiding faith that oil lay in the rocks below and could be found in paying quantities. About two years ago they began acquiring oil territory by purchase or lease, and now control two belts of territory. Their Sunset fields lie along the lowest foothills, eight miles to the south of Buena Vista lake, and comprise a stretch of ground about six miles long by one mile wide. The Buena Vista fields are of about the same extent and lie several miles to the northwest. The surface indications of oil in these fields consist of springs of maltha or liquid asphaltum, which, through the course of centuries and perhaps ages, have slowly flown upward and outward, forming cones of asphaltum which have as steadily been buried by blowing sands and the gravel washed down from the hill. From the top of each cone the black oily maltha slowly oozes and gradually trickles in various directions in sticky, glistening rills. As important and extensive as the production of asphaltum is sure to become in Kern county, it bids fair to be eclipsed by the yield of oil, the recent discovery of which has excited so much attention. About three months ago Superintendent Youle, after a careful study of rock strata and surface indications, started a well about a mile from the main group of maltha wells, and after reaching a stratum of sandstone at a depth of about 200 feet, a flow

of dark greenish oil, entirely different from anything found before, was struck. The oil was subjected to tests and submitted to experts, with the result that it was pronounced to be a natural lubricating oil fully equal to the famed natural lubricating oil found in West Virginia. Lubricating oil is by far the most valuable oil taken from the earth, and the recent strike has established the richness of the Sunset oil fields in the quality of their product. How extensive the yield will be the future must determine but the indications now are that Kern county will have the most famous oil fields on the coast, although other fields have yielded millions.—June 11, 1892.

JUNEAU, ALASKA

Douglas Island.—Low-Grade Ores. — Bear's Nest. — Pine Creek District.—Cape Nome.

The great success attending the milling of the low-grade ore of the big mine on Douglas Island, Alaska, is attracting more attention to Alaska mines. The Douglas Island mine is shipping gold bullion regularly, $74,000 having been sent down this month. The mill has 120 stamps with a full outfit of concentrating machinery, and the ore is being worked at small expense. The mill is run by water power, a Pelton and a Knight hurdy gurdy wheel being used. The ledge from which the ore is obtained is a very wide one, and is in fact a great mass of quartz. The ore is of low grade, however, but there is so much of it that the whole thing is a paying proposition. It is stated that capitalists are now negotiating to put up another big mill on the Bear's Nest mine, which adjoins the Treadwell mine on the north. News from the Juneau mines, on the mainland, is to the effect that they have had severe weather. These mines are mainly worked in the summer.—January 30, 1886.

The first consignment of gold dust from the new Pine Creek district has arrived—300 ounces. The gold is a bright yellow, similar to the Little Manook gold, and free from silver and rust found in Klondike gold. Another stampede is reported to the Hootalinqua, and from $20 to $40 per day to the man is what the pay dirt is said to be running. Many have already left Glenora and Telegraph creeks for the new diggings, and more will follow as soon as provisions can be rushed over to the Teslin. More finds are also reported from the Stickeen. William Reed, of Chicago, owner of the discovery claim of the placer find made on the river, has returned to Wrangel. He says his claims are worth from $6 to $8 a day to the man. Pres. P. B. Weare of the North American Transportation and Trading Co. has had a special investigation made this summer of the coal deposits on the Tanana and Yukon rivers and the copper ledges on the Koyukuk river. He brought down rich specimens of both ores and pronounces the Koyukuk copper samples to be the finest he has ever seen. Weare says mines of both minerals will soon be developed on the Yukon, with every prospect of great profit. A recent report was published in many papers that 3000 Americans were starving on the Teslin trail, between Telegraph Creek and Teslin lake. The U. S. Government asked the Canadian Government to investigate the matter. This has been done and a report received saying only 1500 people altogether are on the trail and that they are well supplied with provisions. The steamer Roanoke arrived at Seattle, Wash., Aug. 30th, from St. Michael, Alaska, with 458 passengers and about $1,000,000 in gold dust.—September 3, 1898.

At Cape Nome all lines of supplies, except dogs, are reported plentiful. Lumber is $250 per M. feet; 100 pounds, a single sack of coal, costs $50. A letter from Cape Nome says: "Bonanza district has been lit on as by grasshoppers and now there is a grand rush for Koksadapagra. The big excitement is at Milk Creek, fifteen miles above Prince of Wales. York is attracting a big lot of attention, and good results are shown. Above Cape Rodney is the latest, called New El Dorado district. The trail is hot with people for this district. There will no doubt be a big stampede for Norton Creek, as $14 a pan is secured. Other creeks yield 10 and 15 cents at the surface. The beach is being worked with good results, and coarse gold at times shows up."—March 24, 1900.

BUTTE, MONTANA

Rich Orebodies.—Sampling Works.—Litigation.

The copper mines of Butte, if more convenient to market, would not be long in attracting the attention of capital. The Parrott (discovery claim), situated on the northern belt, has paid well. Messrs. Downs & Leary have sunk to the depth of 170 feet on the vein, which varies from a few inches to four feet, the ore shipped running from 34 to 50½% copper, and about $30 in silver. The Parrott, No. 1, (W. J. Parks) has attained a depth of 160 feet, ore vein 1½ feet, average for first-class upwards of 40%, second-class after concentration running 45%. The ore is sold on the dump at $55 per ton, leaving a margin for fair profits.—February 3, 1877.

A Colorado company is putting up sampling works in Butte, where ores may be sampled and sold. Thus mine owners who are not sufficiently well fixed to treat their own ores will have an opportunity of ascertaining accurately their value, after which they can sell to the highest bidder. It is an enterprise which will undoubtedly be of great benefit to the class of mine owners mentioned.—January 2, 1886.

The mines and smelters of the Boston & Montana Co. are all closed down and hundreds of men out of employment pending an adjustment of the legal difficulties of the concern. This state of affairs is the outcome of litigation between the Boston & Montana and the Montana Ore Purchasing Co. Suits for unlawful extraction of ore are pending, involving about $5,000,000. The properties of the two companies are worth according to market quotations, nearly $70,000,000.—April 15, 1899.

In the Pennsylvania mining case won against the Boston & Montana by Aug. Heinze, Judge Clancy of the District Court has allowed Heinze $265,015 as costs in the case. He asked for $324,134. The Boston & Montana has a stay of execution and will appeal to the Supreme Court.—September 29, 1900.

DENVER

Pikes Peak Ores.—Clear Creek and Gilpin Counties. — Leadville. —Cripple Creek and Creed.—San Juan Mines.

The Pike's Peak ores contain no quartz. They are iron pyrites more or less mixed with copper pyrites, lead, antimony, etc. The croppings of the leads are a kind of brown granite, containing some quartz and a considerable amount of iron. On sinking upon this, however, veinstone of any kind is not found. The lead is a simple crevice in the granite bed-rock filled with a mass of pyrites. Free gold is sometimes found in the quartzose granite forming the croppings, but is never seen in the ore itself. I was shown pieces of pure granite quite rich in free gold, of a beautifully bright yellow color. I saw but one or two specimens of pure quartz in which gold was to be seen. The veins of pyrites run in a northeast and southwest direction. There are numerous veins of quartz in the country, running almost due north and south. These have never been prospected to any depth. The miners don't like them. They don't want quartz—iron is what they are after.—April 20, 1863.

The Boston and Colorado Smelting Co. are preparing to erect smelting and separating works. They will be located below the Excelsior mill, on North Clear creek.—July 6, 1867.——Two bars of silver bullion were shipped this morning by the Georgetown Silver Smelting Co., their united weight being 342½ ozs., coin value, $460.37½, currency value, $601.08. The repairs on the flue connected with the smelter will probably be finished this week, when the works will again start up with full force.—September 7, 1867.——The Black Hawk G. M. Co. cleaned up and retorted, to-day, 359 ozs. of gold, as the result of one week's work run from 80 stamps, on average ore from their Gregory mine.—September 14, 1867.——This week 15 tons of second-class ore was run from the Smith & Parmslee claim on the Gregory, and the bar as stamped gives the following result: 47 and 28-100 ozs. gold, .864 fine; silver, 110 fine; specie

value—gold, $844.54; silver, $6.62—total, $851.16, or nearly $57 per ton. The assay was $69 per ton, so that the precious metals saved were to the value of 83 per cent. of the contents of the ore as shown by assay. Messrs. Reese, Krause & Bruckner are now running on first-class ore from the same claim, and will clean up early next week.—September 21, 1867.

Manager Ford, of the Wolf Tone, shipped a lot of ore to the La Plata smelting works last Monday, running very high in lead. The shipment consisted of very desirable carbonate ore. The gross receipts from sales of Little Pittsburg ore last month will amount to about $18,000, netting the mine about $7,000. The new No. 9 shaft in the northern portion of the property, near the Amie line, was started up last Saturday. The Green Mountain lode, at the head of California gulch, is working two shifts of men, and accumulating considerable rich ore on its dump. Shipments will begin now in a very short time. The shaft and levels of the Little Silver mine, adjoining the Lee on the east, are undergoing repairs preparatory to the resumption of active exploration work. The mine will be worked by Mr. Kearny and others. The Leopard group of mines, at the head of California gulch, is being worked and producing some ore. At the Matchless mine, more attention is being paid at present to prospecting work than to stoping and extracting ore.—April 22, 1882.

The Imes mine, situated on the crest of Iron hill, will begin shipping a large lot of ore, now on the dumps, in a few days. The Nevada mine, in South Evans gulch, owned by August Rische, is reported to be shipping about 6 tons of ore per day. The Cummings and Finn smelter is receiving 40 to 50 tons of ore per day from the Eagle Bird consolidation, on Battle mountain. The Yankee Doodle mine, of the Carbonate Hill M. Co., is looking well, and continues an output far beyond the expenses of the company. The owners of the Ohio Boy, located on Taylor hill, are reported to have purchased a 20-stamp mill, and at present are making excavations for the same, near Cooper's ranch. Messrs. Berdell and Witherell have placed the major part of the La Plata stock in England. Mr. Thomas Rickard, of London, is now on his way to take charge of these works. The Long & Derry mines have shown up some very fine ore bodies during the past winter, and large shipments of ore from this hill are anticipated during the summer months.—May 6, 1882.

The expectation of those familiar with the ground at Cripple Creek and Creede, is that when the snows disappear and prospectors are enabled to work intelligently, some wonderful revelations will be made. They had just made a beginning last year when winter came on with unusual severity. No prospecting of consequence has been done in either district since last October. Many hundreds have gone in those districts prepared to await the time when they can begin systematic explorations.—February 20, 1892.

Scene of Early Gold Discovery in Gilpin County, Colorado, Gregory Lode Marked by Open Cut.

The Pittsburg company which has been experimenting with the ore of the Klondike mine, at Ophir, to determine the best process for its treatment, has decided to adopt a combination of amalgamation and cyanide, and will construct a 100-ton plant equipped with stamps and amalgamating plates. From the plates the entire product of the batteries will go to the cyanide tanks. The new cyanide tank of the Gold Recovery Co., at Telluride, has begun treating ore.—January 20, 1900.

The Animas Smelting & Refining Co. has incorporated with 100,000 shares at $1 per share. Twenty thousand dollars will be available at once to build a copper matte smelter at Silverton.——T. Allen, Supt. Sampson mill, near Howardsville, has bonded his mine to an Eastern company, which will immediately begin work. Mr. Allen will place a 10-stamp mill at the top of the hill on the Animas river to treat these ores.—March 3, 1900.

The new Smuggler-Union mill is to be equipped with automatic stokers. The Four Metals Co. will put up a mill

to treat the ore from its Palmyra group. The ore in the main vein is about 3 feet wide and is said to average $200 per ton. Work on the new mill on the Gertrude has begun. The San Juan Gold & Silver Recovery Co., one mile from Telluride, proposes increase of its cyanide plant to 200 tons in twenty-four hours. The tailings are principally from the Smuggler-Union mill, and have been washing down and settling on the placer for the past twelve or fifteen years, and it is figured that there are between 200,000 and 300,000 tons of them. The *News* says tests made before the placer was purchased by the present company showed the tailings to carry from $5 to $6 per ton in gold and silver, while assays previous to that gave values as high as $14 to the ton. The company is also handling the tailings which are coming from the Smuggler-Union mills.—March 10, 1900.

BOISE, IDAHO

Mining Districts.—Silver —Antimony Ore.—Climate.

Idaho Territory extends from Nevada on the south to the British possessions on the north; and from the Rocky Mountains on the east to Oregon on the west, and is large enough for at least four good-sized States. The mining localities in the southern parts of the Territory are: Owyhee County, Alturas County, Boise County, and now Ada County is also being brought into the "ring." Yuba, is the principal district in Alturas County, and the Leonora, the most remarkable lode there. The gold is in leaves of about the thickness of ordinary writing paper, with layers of quartz between, and this streak is from two to six inches thick, and is reported to be widening. Mr. William Defrees is working it with a 10-stamp mill. The much spoken of Atlanta, is a lode very rich, sometimes even 40 per cent. in silver, but there is so much antimony with it as to render it very difficult to work, and I am informed that the owners say that they cannot save but a small proportion of the silver. The Lucy Phillips Company (English), Dr. Edward Bishop, director in charge, purpose to rent their mill at Quartz Gulch, in the spring, and to go ahead. The Monarch Company are crushing Atlanta rock, and report good results. Several lodes have been much developed during the past summer. The Pacific has been opened by shafts and tunnels, over a length of 2,700 feet, and the vein found in various places at fifty to seventy feet perpendicularly below the ground. The lode is from fourteen to twenty feet wide, and fourteen tons taken from the shaft of Johnson & Co. worked in an arastra, yielded $22 per ton in gold, but by this, all the silver, which an assay shows is a large percentage, is lost, and much gold also. This was rock just as it came from the shaft, and was not picked over. The Golden Wreath also is in the same position, having been opened and explored for a continuous distance of nearly 3,000 feet, and the shafts, tunnels and cuts, at various points, are from ten to forty feet deep, showing the true vein with its smooth casings. A test of a few hundred pounds in a mortar yielder nearly $25 per ton. The Golden Chariot is almost fabulously rich, and yet the lodes are small, and cost much more to work than at Yuba. For instance, at Yuba, a 400 foot tunnel will strike the Pacific lode at least 300 feet under ground, and ore can be quarried and delivered at the mill, (if erected below it on Grouse Creek) for $3 per ton, at present high rates of labor ($5 per day). Again, the advantage of wood and water is great over Owyhee, but the nearness to traveled trails was what brought Owyhee out first. Now, however, the railroad will pass not over sixty miles from Yuba, and will be the making of that place, and bring wealth to it only to take away for distribution those precious metals that for untold cycles have been waiting to be called forth, for good and for evil, at the hand of man. The climate of Yuba is preferable to Owyhee. At Yuba, the warm springs keep it more temperate, whilst at Owyhee, the snow-storms and continual and terrific winds during winter, are evidenced by the few trees they have. Still Owyhee, as far as wealth of ore is concerned, stands high in the mining districts of the world, and will yet, when it gets out of its infancy, enrich many. The mines of Boise County are apparently doing better than formerly.—December 26, 1868.

SALT LAKE, UTAH

New Installations.—Sampling Works.—Smelters.

The Germania Separating and Refining Works is situated on the west side of the U. S. R. R., about eight miles from Salt Lake City, and were commenced nearly six months ago, and although not yet completed, are now in operation and producing about forty tons of desilverized or marketable lead daily. The buildings are extensive, substantial, and arranged with a view to economy of labor and convenience in manipulation. They consist of the main building, or furnace house, refining house, assay office, engine house and all necessary offices and outhouses, together with manager's and superintendent's dwellings. In the furnace building are five large cast-iron pots, set in substantial brick work, each one over its furnace or fire place, two reverberatory softening furnaces, two calciners, and two flowing furnaces. Connected with this building is the engine house, containing a forty-five horse power engine, and a fifty-five horse power boiler. A little further to the north of this is an inclined shaft furnace, while to the west of the works, at a distance of a few rods is a substantial brick stack, which is connected with the furnaces by means of underground flues of strong masonry. A side track is laid from the main track to the works, by means of which all the materials employed are brought to their respective destinations without trans-shipment. Howland's Mill was the first complete sampling works erected in the Territory, and is situated at the corner of the block due south of the U. S. R. R. Depot, and contains an engine of twenty horse power, which communicates motion to a "Howland Crusher and a Burr stone mill." The whole of the machinery, together with a spacious sampling floor and private office being under one roof. This mill was erected by Messrs. S. W. Howland & Co., of San Francisco, in the winter of 1870, and was by them sold about the fall of 1871, to W. T. Richmond, Esq., of Chicago, who is the present owner. During the last summer it was leased by R. Macintosh, Esq., of this city, who now carries on the business. The Salt Lake City Sampling Mill is situated on the west side of the U. S. Railroad track at the corner of 4th South and 3d West streets, and was built in June, 1871, by Geo. J. Johnson, Esq., who formed a business co-partnership with Messrs. James Lewis & Son, of Liverpool, the firm assuming the name of Lewis, Johnson & Co. The machinery consists of a fifteen horse power high pressure engine by J. C. Hoadley, of Boston, a Brodie crusher and a French burr-stone mill. The building, which is under one roof, consists of a spacious sampling roof 60x40 feet, an engine room, private office, assay office and laboratory. Since last summer the business has been carried on by Mr. Johnson alone. This mill has a sidetrack from the U. S. R. R., and a spacious platform for the reception of ores. H. S. Jacobs & Co.'s Sampling Works is situated one block north of the above, and on the eastern side of the railroad, with a side track for loading and unloading ores. The machinery consists of a very finely finished stationary engine and a Dodge crusher. The sampling floor, engine room and office are in one and the same building. These works were erected in June, 1871, by H. S. Jacobs & Co., of Pennsylvania, and last summer passed to Baxter & Co.—January 18, 1873.

MEXICO

La Dura Mine to Install Chlorination.

Mr. I. Hoffman, of the firm of Kustel & Co., left San Francisco on Tuesday's steamer for Sonora, Mexico, to introduce the chlorination process at the La Dura mine, on the Yaki River. The ore of this mine consists principally of argentiferous zinc-blende, fahlore, and some lead. Heretofore the ore was roasted in two revolving Bruckner's furnaces, with ten per cent. of salt, and then amalgamated in Varney's pans. The amalgam obtained from this operation is so heavily charged with base metals, that the retorted metal is not salable unless cupelled, whereby again some loss of silver must be suffered. There is from six to eight per cent. of copper in the ore, which, at the present mode of working, can not be realized.—October 3, 1868.

JOHANNESBURG, TRANSVAAL

Rhodesian Mining Conditions.—Ancient Workings.—Geology of Districts.—Comparison With the Rand.

Of all the various quests for minerals, to the ordinary man none is so fascinating as that of the search for gold. And of all countries in the world nowhere was there to have been found a surface so redundant, I might say, so saturated with gold; and yet the prospector of Rhodesia is not happy to-day, for after enduring the hardships of pioneer travel, of actual warfare, of poor food and unhealthy climate, he finds that the country which should have rewarded him handsomely for all his pains and toils has been ransacked by some earlier bird, who has got the golden worm, leaving but the form or skin, as it were, of the ornithological delicatessen behind in the shape of the well known "old workings." In comparing these northern gold fields of South Africa with others, this then is the great difference to be noted: Whereas elsewhere the prospector "foreran the royal camp" of promoters, brokers and share speculators, and by the sweat of his honest brow and the strength of his good right arm earned for himself an independence, only giving place to syndicate or company when he had demonstrated the value of his ground and his nomadic spirit urged him "to seek fresh woods and pastures new," here, along with the prospector, must travel hand in hand the middleman, for nowhere can the former find the "actual stuff" to give him even the poorest living, but must content himself with pegging off the empty shell of some "old working" and then handing it over to his companion-in-alms, the promoter, must await the successful begging of the latter in making a flotation. Here in Rhodesia are, so to speak, the self-same gulches that in California or Australia would have supported each its own little community. But, alas, here is no "busy hum of men," for the level lips of the ravine are pock-marked and even the cheeks of the adjacent hills have lost their "bloom," for the ancient has "spread his wings on the blast and breathed on the face of the 'earth' as he passed," and his irritating little shafts are everywhere and so close together that nought remains at or near the surface that will pay our up-to-date prospector to work. And under the conditions in Rhodesia to-day this great incentive of ownership and belief in the property does not exist, and the result is a lax state of affairs most prejudicial to the best interests of the property and its speedy exploitation. In speaking thus of the present system of prospecting and exploiting in Rhodesia, I do not overlook the fact that there are exceptions where honest work is done and intelligent quest conducted, but these are but the exceptions that prove the rule. In the Penhalonga, the Enterprise, the Salishury, the Abercorn, the Beatrice, the Dunraven, the Bonsor, the Tebekwe, the Pioneer, the Queen's and the Ayrshire, the country can show properties that have gone beyond the initial stage, and in some of these the amount of ore in sight can be reckoned in thousands of tons. In numbers of other properties the showing is quite promising, and much exploratory work is being carried on that will without doubt lead in many cases to the uncovering of good ore bodies.

In comparing the gold occurrences in situ with those of other countries we are handicapped by the fact that, except in the few cases of "virgin" reefs, the outcrops have all been previously mined, and while we can see and determine the character of the enclosing rock, we can only tell what the matrix of the reefs is where the "old workings" have been bottomed or the reefs cut below them. In these cases the matrix usually is found to be, as elsewhere, quartz, but it has been a not infrequent experience to discover that the reefs mined by the ancients were composed of some other material; thus in the Ayrshire the matrix was found to be a diorite, in the Gaika a soapstone, in the Johnson of Manica a kaolin, and I have noted other cases where the occurrence may be classed as "abnormal." Hence it is too early yet to state definitely what we must look upon as constituting the Rhodesian ore bodies and what the prospector must look for as indicating his best chance of success. A similar state of uncertainty prevails with regard to the enclosing rocks and the character of the reefs themselves; there have been opposing opinions given by the various geologists and mining engineers who have visited the country. In conclusion I would point out that in gold mining, as indeed in all mining, the surrounding conditions are what govern the question of whether a deposit will pay to work or not.—March 28, 1896.

PRESCOTT, ARIZONA

Hassayampa District.—Jerome.—Bisbee.—Globe.

W. A. Rowe is prepared to ship a carload or more of rich ore from the Davis mine, Hassayampa district. It will go to Argo, Colorado. Col. Bigelow, of the same district, is waiting, patiently, for a home smelter, or the advent of the railroad, so that he can operate his mines with profit. Frank Kuhne has brought to Bones' ore-rooms several hundred pounds of good-looking ore from his Zalida mine, seven miles east of Prescott. John Hutchins, a well known prospector and miner, returned from Silver Mountain district, with rich-looking ore from the claims of Wm. N. Kelly and T. S. Bullock, on the Mammoth mine, which is the biggest mine ever seen by the writer. Olive Camp, 22 miles south of Tucson, not only keeps up its reputation as one of the best chloriding camps in the Territory, but it is rapidly going to the front as one of the most prosperous permanent camps. The mines are improving with depth and the ore grows richer, and every indication and development is full of encouragement.

The appearance of silver as coatings and flakes on copper ore continues in the fifth level of the Globe mine, in Gila county, and forms a separate strata between other beds of ore, indicating the presence of silver ore near by. It is thought probable that an argentiferous vein will soon be discovered, which, in that case, will greatly add to the value of the mine. We are also informed that the owners of the Globe, realizing the importance of cheapening the rate of freights, have signified their intention to materially assist in the construction of the narrow gauge road from Tucson, provided that assurance is given that it will be built to Globe. The owners of the Globe mine have purchased the Interloper, which adjoins the Globe property on its southeast side.—November 13, 1886.

In the tunnel run by W. A. Clark to drain the United Verde Copper Co.'s mines, work has been suspended for the present. The tunnel has been looked upon as a kind of a mystery and many questions made about it since the flow of water; and for the satisfaction of your readers I would say after the flow of the vast amount of water in a few hours the tunnel was filled with sediment and sulphuret ore, while the gulch extending to the Verde river was strewn with the same, which after the exposure to the air and sun now carries all the beautiful hues the corroding copper sulphurets can produce. It is hard to tell the amount of sulphuret ore that passed out of the tunnel in the flow in a few hours; some might estimate it at 500 tons and it might have been many thousand. Soon after the flow had ceased, men were put to work cleaning out the tunnel, which took from four to five weeks, and arriving near where the cave took place, J. L. Geroux had heavy timbers placed in the drift to save the face of the tunnel; he went in after to take a look and saw everything was on the move, and ordered the men to get out, and he at the head made for the incline, followed by the men catching hold of the ropes just in time to save themselves, for the cave followed close after them, crushing the timbers like pipestems, and they had a very narrow escape with their lives. The United Verde Copper Co. is running with good success. Its ores carry considerable silver, gold and copper. Its mine is one of the finest properties in Arizona. The company has two smelters running; no idle men in camp; about 50 to 60 men at work; no place for bummers around the works of the company.—June 8, 1889.

The mining news is good, the prospecting of the Bisbee Co. we learn is satisfactory: the same indications of large bodies of rich copper ore is showing up on these claims as in the Old Dominion. There is no doubt but the claims are all that the company want.—April 4, 1891.

AUSTIN, NEVADA

Isabella.—Troy Morgan & Muncey.—Litigation.

At the close of my last letter we were on Oregon Hill, in the Austin Cañon. A short distance west of the Oregon and North Star ledges are the Isabella and its eastern extension. Both claims look passably well and work is now being prosecuted on both. The Troy is not more than 100 feet from the Isabella. The incline on it is about 40 feet in depth; the width of the ledge 10 inches. In the course of testimony elicited in a recent visit between the Oregon and Isabella companies, some witnesses were of the opinion that the Troy was merely a spur or slide, while others considered it a ledge. If it is only a streak, it is a rich one. The Florida, which has been before the San Francisco Stock Board for some time, has an incline to the depth of 90 feet. Its ledge varies in width from one inch to two feet. Workmen are now engaged on one of its shafts. The Magnolia has a shaft sunk on its ledge, which is about two feet wide, to the depth of 60 feet. The Black ledge and the Cincinnati are about to have war—in a legal way. The S. A. Douglas has a ledge of four feet in width, and an incline on it to the depth of 60 feet. The Morgan and Muncey has a ledge two feet wide and a shaft sunk to the depth of 145 feet. This ledge is considered one of the best in the district. Though the ledge makes some queer curves and angles, it continues so far a well defined ledge. There are only 400 feet in the Company's claim. About one year since a speculator agreed to furnish a mill for a one-fifth interest in the claim, depositing $12,000 as a bonus for the performance of the contract. When the ledge "pinched," he hastily concluded the speculation would prove a failure and failed to perform the contract. He thus retired from the Company minus $12,000. A short distance from the Morgan and Muncey is the Die Vernon. It contains 800 feet, with we know not what depth of shaft, as it appears to be caving. Its ledge is, we understand, two feet wide. The Diana shaft is very close to the Die Vernon, and the ledge is generally believed to be the same. The Diana, being the older location, will be likely to get the Die Vernon's. The Seymour has a shaft upon it to the depth of 50 feet, and a ledge of two feet in width. It appears to be well defined. The Parrott's ledge is four feet wide and the depth of its shaft 60 feet. The Diadem has an incline on it to the depth of 30 feet, its ledge being three feet wide. The Chippewa ledge is two feet in width; work done on it, inconsiderable. There are many other ledges or streaks in the vicinity of those we have mentioned, but no great amount of work has been done upon them. The quartz of the ledges in the vicinity in which we have been strolling is of a blackish color, considerably rusted. As the water line is approached, which is usually at the distance of 75 feet, it changes its character, and for a time the rock yields scarcely any pay. If the ledge does not run out, and work is continued upon it, the rock becomes grayish black, like the Gould & Curry. This rock is very rich, showing sulphurets and even the sulphate of silver in abundance. Some of the rock from the North Star ledge will work $5,000 to the tun. The Mills, Post and White Consolidated are still in litigation with the Black Swan Company. These claims are on Austin Hill, as are also a few of the claims mentioned above. When next I write I will speak of them more fully, as also of the characteristics of Austin Hill ledges as compared with those of Oregon Hill. The weather has moderated much within the last two days. Everybody is gay.—April 23, 1864.

VIRGINIA CITY, NEVADA

Financial Depression.—Mismanagement.—Reopening Mines.

The times in Virginia City are very dull at present, but the conviction appears to be gaining that the worst is over. No one attributes the cause of the depression to any important depreciation in the mines. The constantly increasing shipments of bullion precludes any such idea. The difficulty has arisen mainly from mismanagement. Important changes in that direction have been made which, it is confidently believed will soon restore confidence, and provide immunity for a future occurrence of a similar calamity to any considerable extent. The mines are decidedly improving in appearance. The Savage is now taking out large quantities of bullion. The mine is under most excellent management. Mr. Day the superintendent is very popular with the miners, and can always secure the best labor in the market. Many of the principal mines are increasing the force of their hands. The Gould & Curry have recently added about 100 men to their employ. A large quantity of good mineral is now coming out of their lower gallery, sufficient to keep their own mill steadily at work. The resumption of operations on the Potosi, Bazazette and Golden Era will give immediate employment to several hundred hands, and greatly reduce the number of idle men about the streets. Much interest is being felt in El Dorado, Cañon and the Truckee. The impression appears to be gaining ground that an abundance of coal for home consumption, and even for exportation will soon be raised in the localities above mentioned. We append our usual condensation of the current mining news: The Michigan Company after four years of steady prospecting, struck a fine ledge of quartz last week, which promises to amply reward the prospectors, for the labor and money which they have expended. They are down 400 feet. Have run a drift from the bottom of their shaft to the vein, into which they have driven seven feet without finding the eastern wall. Several tons of rock have been raised, but the water has put a temporary stop to the operations—which will continue a few days only. It is confidently believed that the mine will soon be placed on the dividend paying list. The Michigan was the first location for quartz on Gold Hill, made in 1859, and at a time when all others were locating for surface diggings.—August 27, 1864.

Pioneer Mining Conditions.

Mining Summary

News important at the time and still interesting.

ALASKA

The Scientific Expedition to Alaska, was at Sitka on the 20th of August, waiting for an hour of good weather before starting for Onalaska in longitude 106 deg. The work has been retarded on account of continued rain, fog and wind, with little prospect for the better at this late season. At Fort Simpson the party waited six days and did not get an hour's sunshine. Some developments have been made and hopes are entertained of getting lines of soundings over the fishing banks south of the Fox Islands, but the want of coal deposits will limit the amount of work. When the expedition returns to Sitka, Mr. Davidson will make special local explorations. The Russians and Indians report that the country on the Copper Mine river is very rich in gold, copper and coal. There will probably be valuable diggings discovered there as soon as miners can go thither in large numbers, so as to overcome the Indians,

Map of Alaska, 1867.

who are very bad. Excellent reports are given of the harbor and surroundings of Archangel. The bay is never closed by ice.

October 12, 1867.

With regard to minerals, large and valuable coal deposits were found, convenient to shipping points. Gold is reported by Russians on the Kakuy, a river emptying into Cook's Inlet, about latitude 60°. Copper is reported plenty on Copper River, from whence native copper is brought to the coast by the natives as an article of traffic. The miners from the Stickeen report that they are making an average of $5 per day with a rocker.

November 23, 1867.

ARIZONA

MOHAVE COUNTY

The next district above Castle Dome is called the "Weaver District," and its depot for supplies will be at Olive City. The principal mines in this district are copper, associated with a hard white quartz gangue.

The next district above the Weaver, is the "La Paz", which extends to the eastward from the river some forty miles, and includes the Apache Chief and the Sataza and other mines well known to the public.

The town of La Paz is the largest settlement on the river, and will eventually be the great supply depot for the central portion of Arizona Territory. A good wagon route has been recently explored and located by Herman Ehrenburg & Co., to the new placer mines known as Walker's Diggings, and to the Apache county on the heads of the Gila, and little Colorado rivers.

March 12, 1864.

PIMA COUNTY

The Yellow Jacket mine, on the Ostrich lode, is 75 miles west of south from Tucson, and gold bearing. The owners, Dr. Handy, Bartlett & Co., are working this mine successfully, having a 10-stamp mill, and employing 40 to 50 men. The vein matter is 12 feet wide with a pay streak of over three feet, which works $20 per ton; depth of shaft, 60 feet; length of tunnel, 20 and 30 feet. They have also a parallel vein, 20 feet north, of equal size and richness to the main lode, and a tunnel in some 20 feet; capacity of mill, 15 tons per day; wood and labor both cheap, and a good supply of water.

November 4, 1876.

GILA COUNTY

Globe mining district was organized about twelve months ago. At that time it was confined to Pinal county, but since then a large tract of land has been cut off from the San Carlos Indian reservation and added to the district, said addition being in Maricopa county, and includes the great Apache mountains, in the northeast part of the district, formerly known as the sacred home of the ancient red men, who have been heretofore the great bugbear that has retarded the development of this section of country, which has produced silver ores from the surface, within the last six months, second to no others previously discovered in any part of the Western States and Territories, not only on account of their richness in intrinsic value, but for their mineralogical combinations and crystallization.

September 2, 1876.

YAVAPAI COUNTY

The Badger, is the name of a recently discovered ledge in Big Bug district.

We saw, the other day, a piece of rock from the Patanka lode, in which the veriest ignoramus could detect lots of the pure *plata*. This lode is situated a few hundred yards south of the Sterling lode, in Hassayampa quartz mining district. We are told that the lode crops out for several hundred yards.

J. B. Slack, the owner of the Gross lode, informs us that it is his intention, as soon as the weather moderates in the mountains, to commence work upon the Gross, in anticipation of the running of the Bully Bueno mill, which, it is expected will be set to work in May or June. The Gross is very rich in free gold, and we sincerely hope that sulphurets will not come in for some time, at least.

The last clean up at Lewis & Winning's claim, yielded $10 per day to the hand. A piece weighing over $10 was recently picked up by them.

About two miles below this place, Anderson & Co. are working a bar of Big Bug Creek, and we are assured that they are making good wages.

April 4, 1868.

CALIFORNIA

AMADOR COUNTY

At Jackson several shafts and cuts are being sunk upon veins of auriferous quartz.

Two miles north of Jackson is the Oneida Quartz Mill of twenty stamps, which dates back its existence to the year 1852, although in possession of the present three proprietors but three years. The mill is crushing rock from two claims. The one close by is a vein of hard white quartz from two to six feet wide, and enclosed between walls of black slate, with a shaft down some three hundred feet.

June 11, 1864.

The Eureka, or Hayward mine, owned by Messers. Hayward & Chamberlain, famous as the deepest gold mine in the world, and the deepest mine of any character in California, if not in the United States, being worked to a depth of over 960 feet. This mine is situated on the main Carson lode, and is the richest location ever made upon it. The owners have two mills with an aggregate of fifty-six stamps, and usually clean up at the end of a two week's

run about $20,000. The ore is transported from the hoisting works to the principal mill, on a railroad made of light T rails, laid on cross-ties, after the manner of an ordinary railroad. It is by far the most substantial and durable mining railroad in the State.

March 3, 1866.

CALAVERAS COUNTY

The Union Company at Copperopolis is now working with three engines, running night and day. The Keystone, Empire and Calaveras claims are giving out better prospects of late; and the Webster, a new claim, under the management of Capt. Sanders, is coming rapidly into importance. Schools, Sunday schools and religious societies are taking root at Copperopolis, and altogether the town is acquiring a degree of permanence and character hardly to be expected of a place whose foundations were laid but two years ago.

December 13, 1862.

From every direction we learn of the success of miners, who have started upon veins and commenced crushing the quartz in arastras; some of them actually making money from the surface down. The success of such quartz workers as Mr. Bovee of Angels, and Dr. Southwell of Carsons, has established beyond a doubt the existence of lodes in the vicinity of these places, of the best paying character in the State. While, in the vicinity of El Dorado, West Point, Mokelumne Hill, San Antone, Indian Creek, Railroad Flat, Murphys, Fourth-Crossing, Jenny Lind, Campo Seco, and San Andreas, the prospects are all flattering.

September 23, 1867.

CONTRA COSTA COUNTY

The first result from the Copper Smelting Works at Antioch came down on Monday last in the shape of a bar of copper, the first copper ever obtained outside of a crucible, on the Pacific Coast. Any doubt which may have hitherto existed with regard to the suitableness of Mount Diablo coal for smelting copper has been removed by the success thus attending the first "firing up" of this furnace.

September 21, 1863.

DEL NORTE COUNTY

The Alta California Copper Mine is located in Del Norte county, about eighteen miles from a good shipping point. It was incorporated in 1860. It has an incline 250 feet deep, and is now shipping 20 per cent. ore. It is one of the most promising mines in that county.

October 26, 1863.

MONO COUNTY

The great excitement of the day is the Bodie district, which is situated about ten miles South-west of Bodie creek. The new mines are just below the old diggings. A large number of well defined lodes have been staked off and recorded in the local district office. The rock is of a copper color and contains a small percentage of copper. Rock taken from the top of a number of the best newly discovered lodes assays from $50, to as high as $400 per ton. A new town has been surveyed and lots are held at high figures, while several new houses are in progress of construction—the present fine weather being favorable to the prosperity and progress of the new city.

February 16, 1863.

NEVADA COUNTY

Experiments at Red Dog, Iowa Hill, and other places, have demonstrated that the cement and gravel common to blue-leads, especially in proximity to the bed rock, can be advantageously worked by the crushing process. As a proof of confidence in this new source of mining profits, Mr. Edward Williams, of Red Dog, is now putting up a heavy mill for such work upon his claims. The hard cement in these extensive gravel deposits will not yield to the action of the heaviest hydraulic pipe yet turned upon it. If we are not mistaken, two or three mills of that description are already in operation in Nevada county.

May 21, 1864.

The Nevada *Transcript* says that Mr. Tallman is experimenting in roasting copper ore at Spenceville, which, if successful, will bring into the market a large amount of low grade ore which will not pay on account of the immense cost of transportation. He proposes by the roasting process to expel the sulphur and other constituents of the ore, lighten the weight, thereby raising the per cent. Hundreds of tons of this low grade rock have been taken out, and if measures can be devised for its reduction, considerable money can be realized.

August 20, 1864.

There are fourteen hydraulic companies in the neighborhood of Bloomfield now in active operation. Wm. M. Beck has thirteen men at work in his claims, and is now engaged in running a drift for a grand blast, in which he contemplates using sixty-five kegs of powder. When he cleans up, a handsome result is expected. McCullough & Co. are engaged in "stripping," and after they get to washing their "pay dirt" expect to take out lots of dust. The top dirt pays $6 a day to the hand. Bush & Co.'s diggings are paying $8 per day to the hand, clear of all expenses.

February 11, 1865.

PLACER COUNTY

The Boulder ledge, near Ophir, owned by Daniel Choate, and which was worked about nine years ago, was sold this week to San Francisco parties, for $6,000. This claim formerly produced good rock, but the imperfection of mining machinery, and the great expense attending quartz mining at that time, prevented its successful development. The new purchasers intend giving it a thorough prospecting, and are confident it will prove a valuable mine.

Manzanita Hydraulic Mine, Virginia City.

December 23, 1865.

PLUMAS COUNTY

We learn from the Quincy *Union* that Messrs. Bolinger & Blood's smelting works, in Genesee Valley, are in full blast, and are smelting a large quantity of ore. They will commence shipping merchantable copper in a short time. Messrs. Shelton & Co., have a number of men employed upon their works. They will soon be ready to commence smelting.

September 30, 1865.

SAN FRANCISCO COUNTY

A regular Stock Brokers' Board, upon the same general plan as those of the older cities of the Eastern States, has been formed in this city. The necessity for such an organization in San Francisco at present, does not seem to be very urgent, but the rapid increase of stock companies warrants the belief that the stock brokers may have enough to do hereafter. The officers of the Board are: J. B. E. Cavalier, President; E. W. Teackle, Vice President; Franklin Lawton, Secretary; Henry Schmidell, Treasurer.

October 7, 1862.

The ship Regulator sailed from this port on the 21st ult., for Boston, with about $30,000 worth of copper ore from the Copperopolis (Calaveras Co.) mines. Copper ore has now become a regular article of export from San Francisco. About half a million dollars, in value, from Calav-

eras Co., having already been sent forward. It is time that our capitalists were casting about to devise some means for securing the business of extracting the metal from this ore within our own State. Present appearances indicate that the supply will soon be sufficient to warrant the necessary outlay of capital for the erection of works and concentration of skill, which shall make California independent of the world in this particular.

December 6, 1862.

SANTA CLARA COUNTY

California has some of the richest quicksilver mines in the world. The main quicksilver district lies in Santa Clara county, about sixty miles northward from San Francisco, and twelve miles south-westward from San Jose, in the coast mountains. There are three mines here; the New Almaden, which derives its name from the quicksilver mine of Almaden, in Spain; the Enriqueta, so styled in honor of Enriqueta Laurencel, a little daughter of one of

Old Tuolumne.

the proprietors of the mine at the time of the discovery; and the Guadalupe, a name suggested by the little river that drains the district.

May 25, 1861.

SHASTA COUNTY

The Shasta *Courier* says that the Highland mill, of French gulch, recently cleaned up $4,000 after a run of nine days. They subsequently cleaned up $2,500 after a run of five days.

January 21, 1865.

At the Pittsburg Copper mines, the original Williams & Kellinger company have commenced shipping ore below. They are also engaged in constructing arrastras to crush some gold-bearing rock, which is found in their claim, and which is known to be very rich. Much stock in this company has changed hands of late, at high figures per foot.

January 2, 1864.

The Copper City *Pioneer* says the principal offices of the Pittsburg mines should be located at Copper City; the Red Bluff *Independent* thinks Red Bluff is the proper place; the Shasta *Courier* thinks his cotemporaries must be joking and is quite sure that Shasta is just the place for all such offices.

May 28, 1864.

SIERRA COUNTY

Quartz prospects are still lively at the mines about Alleghany. The Union is still getting fine prospects. One small piece of rock about the size of a goose egg, worth about $75, was lately taken out where they are working. The annual meeting of the Fac Similie Company was held last week, and the old board of officers elected, as follows: J. H. Clute, Trustee; M. V. Clute, Treasurer; L. McKelvey, Secretary. The ledge prospects splendidly as the work goes on.

December 23, 1865.

TUOLUMNE COUNTY

App's mill is somewhat over a mile from the town, near the old "Wood's Crossing." The rock of this company has been paying well for years. During my stay in the neighborhood, 20 tons from a shaft considerably deeper than they have previously used, averaged $75 a ton. The machinery is, however, imperfect, and loses, as is now ascertained, at least one-half the gold. Mr. App has recently put one of Varney's Amalgamators in use. The first experiment on the *tailings*, paid at the rate of $30 a ton; the second, with an application of steam, paid $10 more.

The Confidence mill is 10 miles from Sonora, now working rock from the Comstock and Smith veins, and averaging from $60 to $150 per ton.

Sonora, January 23, 1864.

YUBA COUNTY

The Blue Gravel Company, at Smartsville, have had another clean-up, realizing $50,786. This is another clean-up since the 14th of March, the first being $46,000; the second $26,708, and the third as above, making in all, for three months, $123,576. The earnings of the company for the present year promises a much larger yield than the past year, when their net earnings were over $200,000. This, for a hydraulic claim, is probably unequalled in the State.

Rich gravel diggings have just been discovered in the main street of the town of Brown's Valley. Several pieces of gold, valued as high as $60, have been taken out.

June 24, 1865.

COLORADO

GILPIN COUNTY

The Black Hawk (Colorado) *Mining Journal* says that Messrs. Keith, Moller & Co. have decided to throw aside the Frieberg pans and substitute therefor the Plattner (chlorine) process for working the sulphuret ores, which abound to the exclusion of almost everything else in the mine belonging to that company, and indeed in most of the mines of Pike's Peak. This company, it will be recollected, is the one which has so successfully introduced a new process, known as the "Keith's Process," by means of driving, with a blast of air and flame, the finely divided particles of ore through a long furnace, the particles of ore becoming desulphurized in their passage.

June 18, 1864.

MINERAL COUNTY

Creede, a possible new camp, has six shipping mines, with five others in large bodies of good ore and in good condition to forward large consignments to the smelters. The Amethyst tramway being completed, is bringing down from the Amethyst and Last Chance sufficient ore each day to load 15 to 20 cars. The Del Monte the latest wonder, if not at the head of the list is very near it in strength of vein matter and value of ore. In some of the outlying districts where prospecting has been active since the snow disappeared, some valuable discoveries have been made. The latest reports are from the vicinity of Cunningham gulch, 35 miles up the Rio Grande from Creede. The mineral is oxidized lead and iron. The surface is comparatively free from wash, with rocks exposed so that prospecting is a very simple matter. The vein which has excited profound interest and will cause a rush to Cunningham if present accounts shall be verified, is said to be 18 feet wide with a pay streak of five feet which averages $225 in gold and silver and 40 per cent. lead. It is simply a

prospect as yet, but a very promising one. The assay value as just defined is sufficient to induce rapid development.

July 23, 1892.

TELLER COUNTY

At least two of the recent mining excitements have turned out well and with good results—Cripple Creek, in Colorado, and White Hills in Arizona. Of course some of the claims concerning them were exaggerated at first, and as yet there have been no very extensive deep developments. Still, the prospects are quite favorable. In the White Hills the ledges are small but rich, and not the kind that big companies care to take hold of. In the Colorado camp, however, a good deal of capital is being invested and a branch railroad now being built will insure cheap transportation. There has been more of a rush to Cripple Creek than to the Arizona camp, but in both cases the miners who went have remained. This is a good indication of permanency in both districts.

December 24, 1892.

IDAHO

OWYHEE COUNTY

This week a mass of silver, streaked with a little quartz, was found in the Rising Star mine, Flint District. The silver is as pure as the assayed bars, and the celebrated Poorman is, in comparison, an ordinary ledge. The Morning Star mine is yielding immensely rich ore. The ledge, at the point from which the ore is now being taken, is one solid mass of black silver, the latter predominating. The original Hays & Ray is yielding ore of the same character, and equal in richness with the Poorman.

December 30, 1865.

The richness of the Oro Fino ore increases with depth of working. Gold is visible in a large portion of the quartz in the vein. The Morning Star mill is kept constantly at work on ore from the mine.

The ore from the Ida Elmore is now being taken from the depth of 80 ft. Steam hoisting works have been erected at the mine.

The main body or rich streak of quartz in the Golden Chariot, shows a width of about two ft., the remainder being composed of horses of granite and veins of quartz a few inches wide. The ore is of the same quality of richness as that of the Ida Elmore. The gold can be seen in almost any of it.

December 21, 1867.

The parties owning the Ida Elmore and Golden Chariot mine have finally come to the conclusion "to fight it out on that line," and accordingly the fight has commenced in earnest. The partition wall between the two working parties has recently been broken through, disclosing the fact that the two mines or claims, were on one and the same lead. The combatants have fortified themselves in the stopes and drifts, and both parties seem determined to hold their "grip". The Ida Elmore party are preparing hose by which to eject hot steam and water upon their antagonists. About 40 shots were exchanged on Thursday.

April 4, 1868.

SHOSHONE COUNTY

There has been more or less difficulty at Coeur d'Alene, Idaho, for a long time between the mine-owners and the Miners' Union of Coeur d'Alene. This organization comprises the unions of Wardner, Gem, Burke and Mullan districts. Over a year ago, when the mines were working, everybody got $3.50 per day. The mines were finally shut down owing to excessive rates charged by the railroad for taking the ore to the smelter. The mines were to start in April, and then the wages of shovelers, carmen and other surface laborers were reduced to $3 and their time of work increased. The men refused to work on this basis and miners were brought from California and elsewhere to fill their places in some of the mines. On Monday of this week the strained situation culminated in a fight at the Gem and Frisco mines, at the town of Gem, between Union and non-union miners. Five men were killed and 16 wounded. The Frisco mill was blown up during the fight and is a complete wreck.

July 16, 1892.

MONTANA

LEWIS AND CLARK COUNTY

Mining above Cave gulch is turning out better than the prospects promised early in the season. Mining in Montana gulch is being prosecuted with vigor. A large force of hands will be at work on the Rumley mine in a few days. The placer mines at Bannack are furnishing a fine supply of gold. Several rich discoveries have recently been made in the Trapper district. Several placer claims have been purchased by Chinese in Emigrant gulch. Eighty-four tons of ore from the Acquisition Spur lode, at Butte, have been shipped East for reduction. Copper ore from the Park mines is going forward to Salt Lake for smelting. Three shafts have been sunk on the Trevonia lode—one of them is to a depth of 70 feet. A splendid nugget, assaying $145, arrived yesterday from the Snow Shoe mines. Twenty thousand dollars in gold dust was sold in Helena Monday, and $21,000 on Wednesday. Twenty-two tons of second grade ore from the late Acquisition Spur lode sampled $400 to the ton. A streak of $500 ore has been found on the Clear Grit lode near Butte. A fine clean-up was made last week on El Dorado bar. The mines in Henderson gulch are being worked with fine results. There is plenty of water to work the Nevada creek mines. Miners on Spruce bar are taking out good pay. Several new mining claims are being worked on Boulder bar. The Rochester mill is working rich ore and makes a fine showing in silver bullion. The Willow creek mines are turning out well.

July 29, 1876.

SILVERBOW COUNTY

A full supply of water enables the placer miners to continue work night and day upon the claims below Butte and heavy returns from this year's work are expected by all engaged in this branch of mining. If in the other camps throughout the Territory as much success has been met with as in this one there will be no scarcity of gold at the end of the season. On Davis' arastra they have commenced amalgamating the rock crushed but it was of an extremely low grade ore intended simply to fill up interstices and test the working power of the machinery. The ore secured by Mr. Davis which is now being crushed is a medium grade and will probably average about $120 to the ton.

July 15, 1876.

The Butte placers are yielding $500 per day. Mr. Esole continues work on his claim in Silver Bow creek, and is doing well. The Dexter mill will start up again to-morrow, all breakages having been repaired. There are rumors of more mills being put up in Butte within the next three months, but we are unable to give facts at present. In the Mountain shaft at a depth of 15 feet, foul air was encountered, and Messrs. Cameron & Co. are running a day and night shift and hoisting large quantities of first-class copper ore daily.

August 5, 1876.

The La Plata company have contracted with Mr. W. A. Clark to supply him with 500 tons of ore, Mr. Clark agreeing to take it all within a specified time. He will not make a continuous run on this ore, but work a certain amount each month and purchase smaller lots from other mines, in this way aiding in the general development of the camp.

September 23, 1876.

NEVADA

HUMBOLDT COUNTY

The Rye Patch mining company shipped last Wednesday, bullion valued at $6,300, the result of one week's run with five stamps, one of the batteries being out of repair.

September 16, 1876.

LANDER COUNTY

Between the city of Austin to-day and six months ago there is a striking contrast presented. Then, it is true, it was as large as it is now; but what were then brush houses and holes in the side of Austin Hill, have now become comfortable tenements of either wood or stone. The present population cannot, however, exceed 1,800; a great

number of persons who went to California to winter, either not having returned or having directed their attention to the "outside" districts. All of the mills in this cañon are at work pretty steadily, and are turning out a large quantity of silver in proportion to the quantity of rock crushed. Ten tons from the North Star recently produced $7,000. The rock from this ledge sparkles with virgin silver. This company is not incorporated, nor is any of it in the market. The Oregon (not the company of that name incorporated in your city,) Savage, Morgan & Muncey, which are located near the North Star, are also holding good their reputation as first class claims.

April 16, 1864.

The Esther lode, situated directly within the city of Austin, is now turning out most excellent rock. The results of the first crushing from this lode were very discouraging, and ran the proprietors something in debt. Not at all discouraged, however, and believing that the ore was not properly handled at the mill the proprietors again went to work and took out two tons of first class ore which they hauled to the Pioneer mill, and realized $2,523—a very satisfactory result indeed. Another lot of two tons was next crushed and yielded $3,930. Several hundred dollars were also realized from the saie of specimens. Two tons of second class ore were then tried, which gave $604.77. The are was taken out by two men, in two months. After deducting all expenses, reckoning labor at $5 per day, the net profits of the operation were $5,600.

August 13, 1864.

STOREY COUNTY

More than the usual amount of business has been transacted in the Stock Boards since our last issue, notwithstanding the joyous influences of the holiday season. Gould & Curry is rapidly tending upward; $5,000 is offered, while holders are scarcely willing to sell at $5,025. The reports of the President and Secretary have been published, from which it appears that the affairs of the company are in a highly prosperous condition.

The largest clean-up ever made from one day's run of the Gould & Curry mill, was on the 23d instant. The weight of unretorted amalgam taken out was 3,555 lb. This will make about one-fifth that weight in bars, and is worth in the neighborhood of $20,000.

Ophir, since the refusal of the injunction asked against the Burning Moscow, has declined somewhat and cannot now be quoted at over $1,490. The December dividends have also shared somewhat in the depression. A large number of sales have been made during the past five days, commencing at $40 and gradually declining to $25 on Thursday.

January 2, 1864.

WHITE PINE COUNTY

B. B. Martin, the owner of the Tallahassee mine, on White Pine mountain, has just received returns from a lot of ore he sent over to the Richmond works, at Eureka, which assayed $137 in silver and 40 per cent. lead. The company allowed him $70 per ton for the ore.

September 9, 1876.

SOUTH DAKOTA

LAWRENCE COUNTY

There are some 10 "cities" and 30 different Miners' Camps in the Black Hills. The principal cities are Deadwood and Custer. The latter last year was the supply point, and contained 3,000 inhabitants. It has now dwindled down to 400. There are Hill City, Lead City, Montana, Gay City, Elizabethtown and other camps. The total population now in the "hills" is thought by the best informed to be about 10,000. How much gold has been taken out by this swarm of prospectors it is hard to tell. Some think it will exceed some $750,000. But even this would be poor wages for the three months' work of 10,000 men, supposing all had given their time to mining. On Bare Butte creek the First Silver Discoveries have been made, and a new town called Galena laid out. Twelve tons from one of the lodes has been sent to Denver for reduction. It is claimed to be very rich. There are over 20 well developed ledges at Galena. There seems to be a belt of "lodes" three or four miles above Deadwood City in which the quartz is quite rich. From $15 to $20 a pan has been taken out in some places. But the lodes are not what experienced miners would call "well defined." They seem to be mere blow-outs or decomposed rock, and since there are no regulariy defined veins the miners have doubts about their holding out. Without doubt all the free gold in Deadwood gulch comes from this quarter. Negro Gulch district, 40 miles from Deadwood, is very promising, but there is lack of water. Parties in from the Big Horn country bring discouraging news. They report no gold, and great hardships in their prospecting tour. This is against the general expectation, as the Big Horn has been regarded as fabulously rich, but very few have ventured in there owing to the Indian troubles.

November 25, 1876.

UTAH

SALT LAKE COUNTY

Evidences of the vast wealth concealed in the mountain ranges of this Territory accumulate daily. In the Wasatch on the east, and in the Oqurrh or West Mountain range, silver, copper and lead have been discovered. In Bingham Cañon, in the latter range, ledges of silver and copper are now being worked, and before Spring, both saints and soldiers will be amazed at the rich developments. On the west, at Deep Creek, at Antelope Springs, at Egan Cañon and Washoe Valley, ledges of silver equal to Reese River and Washoe have been discovered, prospected, and some are being worked. On the north, at Butte Creek, placer gold mines are paying the Morrisites richly, and at Hickman's Butte a whole mountain of cinnabar has been discovered and will be worked in the Spring. Still further north, on the Snake River and the Blackfoot: golu diggings equal to the Boise and Bannock have been worked all Summer. In fact the whole Territory is one vast deposit of rich minerals, only awaiting industry and intelligence to develop it.

December 14, 1863.

TOOELE COUNTY

In East cañon, Ophir City, is the new camp. Country rock limestone. The chloride veins are very irregular and "pockety." Some of them a month or so ago paying immensely, but now with little or no ore in sight. The ore averages $225 to the ton, and as it is nearly as soft as earth, when they do strike a pocket the daily product is often very large—10, 15, 20 and 25 tons. The Mountain Lion looked the best of any and has an open drift, 40 feet long, on one side of which is a wall of chloride 2½ feet thick, which runs from $200 to $400 a ton. The big stories about the Emma are all true, or seem to be, it often turns out 100 tons of good ore a day. Following is a telegram dated Stockton, (Utah), March 19th: Rich chlorides have been discovered in Soldier Cañon, about six miles east of here, and the town is almost deserted. It is mostly float that has been found.

March 25, 1871.

CANADA

A Milwaukee newspaper speaks of important discoveries on the northern shore of Lake Superior. The Indians and trappers of this region have often brought pieces of silver ore into the settlements. This has given rise to a general belief that when the shore should be thoroughly explored, deposits of this precious metal would be found. This isolation and ruggedness of the region, however, have discouraged private enterprise, and the peculiar land policy of the British Government has prevented the formation of mining companies. Veins of ore have been profitably worked at the mouth of Pigeon River and on Prince's Bay, but elsewhere little or nothing has been done until within a year past. It is about a year since a Mr. McKeller, of Ontonagon, discovered indications of a silver deposit at the head of Thunder Bay. This summer other persons have prosecuted the search, with very favorable results. Two veins have been found carrying paying quantities of native silver, and several others bearing "silver lead". One of the veins with native silver also carries a notable quantity of argentiferous sulphuret.

December 21, 1867.

Special Correspondence

MEXICO

Oil War.—Guanajuato Development. — Hidalgo Smelter. — Dos Estrellas.—Yaqui River Smelting.—Sonora Mining.—Lawson Collapse.

H. Clay Pierce, head of the Waters Pierce Oil Co., is now in Mexico, presumably to watch the oil war at close range, and announces that he will remain for several months. Sir Weetman Pearson, head of the Pearson-Aguila interests, who is now in the Argentine, is expected in Mexico within a few months. A meeting of the two men in this country, with the settlement of the oil war as a result, is not considered unlikely. The losses of the oil fight so far have been heavy, and both sides have shared in them, but the exact proportion is difficult to estimate. A division of territory is considered a probable basis of settlement, although the purchase of the Pearson holdings by the Waters Pierce is conceded to be a possibility at any time. Just now the Pearson-Aguila interests claim to be in better condition than at any time since the oil war opened. They announce that the delivery of oil from the Furbero fields in Vera Cruz has been made possible by the extension of the pipe-line under the waters of Tuxpan harbor to buoys outside the bar, and that the first shipment has been made by tank steamer to the Minatitlán refinery. The Furbero fields are credited with several producing wells, and the Pearsons have a contract on the production up to 6000 bbl. per day, on the strength of which money was advanced for a railroad and pipe-line to the Gulf port of Tuxpan, 83 kilometres distant. It is also announced that wells recently brought in at Tanguijo and Potrero del Llano, also in Vera Cruz, are showing good production, and that pipelines will be built to handle the oil. If these sources of supply hold out the heavy importation of Texas oil, necessary for several months to enable the Minatitlán refinery to supply demands, will cease. When the Pearson-Aguila interests launched the oil war they believed they had native oil supplies in sight for all requirements, but their wells failed to come up to expectations. It is reported that the Mexican Fuel Co., a Waters Pierce concern, is experiencing difficulties at wells brought in at Santa Fe, in the Topila district of Vera Cruz, casing having collapsed. The opening of the Huasteca fields of the Huasteca Petroleum Co., a Doheny concern, will be of benefit to Waters Pierce, as it has contracts with the Doheny interests for crude oil. A pipe-line that will deliver Doheny oil at Tampico is being rushed to completion.

The Oro Grande Mines Co., organized to re-open the famous old producers of La Luz, Guanajuato, has made a deal for control of the Guanajuato Amalgamated Gold Mines Co., owning mines and a reduction plant in that district. The acquisition of the reduction plant, which consists of 100 stamps, concentrators, and cyanide annex, will make possible the immediate milling of dump ore and mine filling from the Oro Grande properties. The plans of the Oro Grande included the erection of a 1000-ton plant, and it is now stated that the Amalgamated plant will be enlarged. The Guanajuato Amalgamated was for a time in the hands of a receiver, but under the management of W. H. Puffer the concern was placed on a profitable basis and the receiver discharged. The first subsidy payment of ₱7500 has been made by the Mexican Government to the Mineral Development Co. for the Nueva Luz shaft in the Guanajuato district. This is for the first 50 metres below the 500-metre level. The shaft will prove the mother lode of Guanajuato in depth, and the Government is interested to the extent of paying ₱150 for every metre below the depth mentioned. At 2000 ft. a cross-cut will be driven to the mother lode, and a second will be run from 150 to 200 ft. lower. During the ten months ending with April a record of 64.5 ft. per month was made in sinking, the shaft starting the present month with a depth of 1818 feet.

The erection of a custom smelter in the State of Hidalgo is now said to be certain as a result of the gratifying manner in which the Flojonales copper mines are developing. These are the property of the Robt. S. Towne interests, purchased last year for ₱100,000. The smelter will open to ores from other mines in the Zimapán and Encarnación sections of Hidalgo. An electric railroad to Sayula, on the National Railways, is contemplated, and in anticipation of power needs the Towne interests have secured water-power concessions on the Tula, or Ixmiquilpan, river.

The Dos Estrellas Mining Co., owning the great Dos Estrellas mine, has increased its dividend rate to ₱3 per share quarterly, a distribution of ₱900,000 every three months. Dividends paid last year amounted to ₱3,000,000. The ore extracted last year reached a total of 348,580 tons, at an expense of ₱7.09 per ton, and the milling cost was ₱3.04. The ore reserves at the end of the year were over 2,018,000 tons.

The re-opening of the old Mina Grande, in the Hostotipaquillo district, has been commenced by a company of

Mining River Bed, Guanajuato, Mexico.

French capitalists. F. J. Fournier, the Dos Estrellas millionaire, is one of the stockholders. The property was purchased last year from the Dwight Furness Co., of Guanajuato, for ₱75,000. The Vick Mining & Milling Co., owning the old Espada, Deseada, and San José mines in the Hostotipaquillo district, will build a modern plant for concentration and cyanidation next year. Development so far has placed in sight about 45,000 tons.

The Guanajuato Power & Electric Co. has started construction on a transmission line to San Luis Potosí, a distance of 87 miles. It is also planned to place power in the Pinos district of Zacatecas. The Guanajuato Power & Electric Co. and subsidiary concerns have so far invested $6,000,000 in power plants, transmission lines, and distributing stations in Mexico. There are two hydro-electric plants in operation in the State of Michoacán, and a third, now under construction, will give a total capacity of 20,000 hp. by next year.

The custom smelter of the Yaqui River Smelting & Refining Co. at Toledo, Sonora, is about to go into commission. The smelter has a capacity of about 180 tons per day. An experiment with natural coke from the Barranca coalfields belonging to the Southern Pacific is to be made, and if this can be used it will reduce operating expenses. The Sunset Development Co., a Southern Pacific concern, is working 150 men at the coalfields. The 60-ton cyanide plant of the Barranca Mines, Ltd., of London, at Las Goteras is nearing completion and will be soon in commission. It is one of

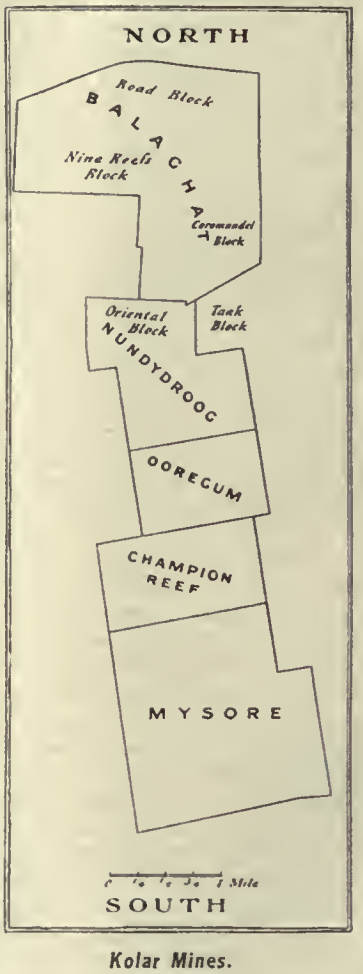
the most complete cyanide plants in Sonora. Ore supplies sufficient to keep the mill in operation for two years have been developed. The Wyman Mining Co., at San Javier, is operating its 50-ton concentrating plant and shipping some high-grade ore. Surveys for the projected narrow-gauge railroad across the Sahuaripa district of Sonora from a connection with the Southern Pacific at Tonichi to the camp of the Cienegulta Copper Co. and beyond are in progress. It is stated that construction will commence in October. The financing of the railroad is in the hands of a syndicate headed by Charles Deering, of the International Harvester Company.

The reduction plant, silver-gold mines, and valuable water rights of the Lawson Mexican Development Co., a Thomas W. Lawson enterprise, in the Mascota district of Jalisco, are to be sold at auction for the benefit of creditors. The properties have been appraised at ₱85,761, and no bid of less than ₱57,214 will be received by the court. The amounts involved in the attachment total about ₱40,000. The Lawson investments in Jalisco have been far in excess of the appraised value of the properties attached. Capital was first provided for the erection of a furnace at the cinnabar mines, and later it developed that the ore was too low-grade. The custom plant followed, and the failure of this enterprise is now attributed to the fact that the Lawson mines were not developed so as to supply the mill. The Mexican Iron & Steel Co., a Boston concern that recently purchased the Tula iron mines in the Tapalpa district of Jalisco, is placing a bond issue of $1,500,000 in France. Plans are afoot for the reorganization of the Oaxaca Smelting & Refining Co., with the object of operating the custom smelter at Oaxaca.

LONDON

Kolar Mines, Ooregum, and Balaghat.—Kalgoorlie, Horse-Shoe, Ivanhoe.— Taxco Mines of Mexico.

The names of the Kolar mines, running from south to north, are: Mysore, Champion Reef, Ooregum, Nundydroog, and Balaghat. Of these Mysore has been the most consistent producer; the next three have had anxious times at various points in depth; but Balaghat has not been favored by fortune. The Ooregum company was formed originally in 1880 and reconstructed in 1885. Production commenced in 1888 and dividends in 1891. Though not as large a producer as Mysore, Champion Reef, and Nundydroog, the mine has done well, and the total dividends distributed up to the end of 1909 have amounted to £1,715,355. The average content of the ore mined has periodically shown decreases. One such period of depression occurred during the years 1905-7, and the dividend paid for 1907 was only £38,353. Since then the grade has improved, and during 1909 it was 12½ dwt., as compared with 8¾ dwt. in 1905. For 1909 the dividends amounted to £120,231, and the general position is decidedly encouraging. The amount of ore crushed during 1909 was 125,349 tons and the yield in the battery was 79,181 oz. bullion. In addition, 114,748 tons of tailing was cyanided and yielded 12,677 oz. bullion, and 5378 tons of slime was treated in an experimental plant yielding 205 oz. The total production of gold was 82,346 oz. fine, an increase of 5811 oz. over 1908. The gold realized £349,012, and the working expenses were £184,493; other small items in income and expenditure left a profit for the year of £151,973. Out of this, £5866 has been paid as income tax, £27,894 has been written off capital expenditure, and £120,231 has been paid as dividend as already mentioned. This dividend corresponds to 40% on the 240,000 preference shares of 10s. each and 30% in the 481,544 ordinary shares of similar denomination. The old original lease for 30 years has just expired and the company entered upon the new lease on March 22. The working expenses will show a marked decrease during the current year, as the cost of power supplied by the Madras Government's electric generating station at the Cauvery Falls has been lowered from £24 to £10 per horse-power per year. The total ore reserve on December 31 was 157,582 tons, an increase during the year of 3300 tons. Some rich ground has been proved to extend to the lowest workings, 3810 ft., and the continuity of this shoot is highly encouraging for the current year's prospects. The Balaghat was started in 1886 and there have been three reconstructions of the company. It was not until 1900 that dividends were paid. Subsequently the output and profit were gradually increased, until in 1905 and 1906 dividends of £55,000 were paid. In 1905 the output realized £164,203, and in 1906, £178,898. Since then the output has seriously fallen and the results for 1909 are far from encouraging. During the year 7136 ft. of development work was done, with only disappointing results. On December 31 the reserve was 29,353 tons. During the year 37,350 tons of ore was milled, producing 18,285 oz. bullion, and 54,970 tons of tailing yielded by cyanide 2918 oz. The total gold realized £81,028. The battery worked at only two-thirds capacity. It is proposed to continue at the present rate, about 3000



Kolar Mines.

tons per month, but if development results do not improve, the position of affairs will have to be seriously reconsidered.

The interest in connection with the Kalgoorlie group of gold mines in Western Australia is nowadays divided between the study of the persistence of ore in the deep levels of Great Boulder Proprietary, Ivanhoe, and Golden Horse-Shoe, and the rearrangements and consolidations among other mines, some of which have low-grade ore and no mill, and others a plant but only exhausted stopes. As regards the Proprietary, the ore has been proved to 2600 ft., and as this lode passes into the Horse-Shoe, the latter, being as yet only 1700 ft. down, is rejoicing in its prospects farther down. The official details about Horse-Shoe and Ivanhoe have been published this week and are of interest in showing the positions. At the Golden Horse-Shoe, during 1909, 263,361 long tons of ore was sent to the 150-stamp mill, where 39,135 oz. gold was recovered; subsequently 18,609 tons of concentrate was roasted and cyanided, yielding 37,437 oz. gold; 51,574 tons of sand was cyanided and yielded 8155 oz.; while 193,178 tons of slime yielded 52,828 oz. In addition, 12,751 tons of tailing was re-treated, producing 3003 oz., and cyanide slags yielded 2165 oz. The total production of gold was therefore 142,723 oz. The percentage of extraction, excluding that from re-treatment, was 87.7, and

the average extraction per ton was 46s. The income from the sale of gold was £606,316, and the items of cost were as follows: mining, £135,225; extraction, £148,661; maintenance, plant, etc., £17,134; development, £28,212; management, £13,524; London expenses, £7233; duties and taxes, £13,868. The balance of profit was £242,870, out of which £240,000 has been distributed as dividend. Since operations commenced in 1899 the output has been 1,746,751 oz. from 1,904,235 tons of ore, and £3,000,000 has been distributed as dividend. It is noteworthy that practically the whole cost of mine development and machinery has been provided out of income; the figures being £319,171 and £500,059 respectively; also that the content and cost have both been greatly reduced. In 1902, 122,019 tons yielded 193,677 oz. at a cost of mining and milling of 55s. per ton; in 1909, 263,361 tons yielded 142,723 oz. at a cost of 22s. 9d. Costs might still further be reduced, and an intimation that this will be so is given by the engineer. It is necessary to guard against superficial comparison with adjoining mines where the short ton is used. The ore reserves on December 31 amounted to 1,071,638 long tons averaging 11 dwt., a figure practically the same as at the beginning of the year. The reserve is only calculated to the 1650 and 1767-ft. levels on the two chief lodes; these lodes have proved to go down to 2000 ft., but development is not sufficient to warrant any estimate of the ore in the lower parts. As already mentioned, the adjoining mine on the eastern boundary, the Great Boulder Proprietary, has proved to 2600 ft. a lode that passes into the Horse-Shoe, so altogether the prospects of the Horse-Shoe for the future are good. The Ivanhoe mine is surrounded by the Horse-Shoe and the Great Boulder Proprietary. It originally formed one of the Whitaker Wright flotations, having been purchased by the present company in 1897 from the Melbourne owners. After the collapse of the Wright régime, Bewick, Moreing & Co. became consulting engineers. Large profits have been made since the beginning and dividends amounting to £2,470,000 have been paid by the English company; during the same time the output of gold has been 1,310,908 oz. fine, valued at £5,587,674. At the present time the position is that the lode has been cut at the lower levels, 1970 and 2120 ft. Though the content is low at the point of intersection, at the 1970-ft. level it increases as the level is continued, and at one point some valuable ore has been cut. The ore reserve above this level amounts to over one million tons with an average assay-value of 45s. 8d., which is an increase of 73,700 tons during the year and a decrease of 4s. in value. During the year 1909, the ore sent to the 100-stamp mill was 231,063 tons. By amalgamation gold valued at £137,586 was obtained; 21,051 tons of concentrate was roasted and cyanided yielding £122,082; 104,218 tons of sand yielded £67,874; and 105,794 tons of slime gave £171,710. The total extraction was therefore £499,253, and the percentage of recovery was 88.3, which is an improvement of 1.53% over 1908. During the year one of the improvements introduced was aeration of the roasted concentrate before agitation with cyanide. A screen has also been introduced to eliminate the fine before the ore is sent to the grinding pans. The cost of treatment was £241,549, which includes development, mining, extraction, and general expenses. This is at the rate of 20s. 11d. per ton, and is practically the same as during 1908. After paying London expenses, taxes, etc., the divisible profit was £248,585, out of which £240,000 has been distributed as dividend. It is worth noting that altogether £759,353 has been written off the expenditure on development, plant, equipment, etc., and that the company has a reserve fund of £208,499 invested in first-class securities, mostly debentures of English railways.

One of the most interesting recent promotions in London is the Taxco Mines of Mexico Limited. This company has been formed to acquire the old Rosario silver mines in the mining district of Taxco, Guerrero. The properties have been recommended by T. R. Marshall, of London, and are presented with a report by Ezequiel Ordoñez. The oxidized silver ore of the district was worked successfully by the patio process in past years, but the sulphides were not amenable to this treatment and operations were suspended. During recent years the use of fine grinding and cyaniding has been proved successful on similar ores in Mexico, and the intention is to apply this treatment here. A plant to treat 90 tons per day is to be erected. The ore in the lodes is irregular and there are many barren spots, but much of it is valuable, though low in grade. The bunches and stringers that formed the sole basis of former work were numerous. The veins consist of quartz containing silver sulphide with some gold. The ore that is left in the old stopes averages 20 oz. silver and 1 dwt. gold per ton. The richer bunches and stringers were extracted by previous workers and sold to smelters, and there is every reason to suppose that when development is undertaken in virgin ground similar rich patches will be found. The capital of the company is £60,000, divided into 240,000 shares of 5s. each; of these 120,000 go as purchase price to the vendors, and 80,000 are being offered for subscription, the remainder being retained for future issue. The promoters are C. W. Whittemore, director of the local company, and L. T. Boustead and D. J. L. Anderson, of London.

MANILA, P. I.

Private Work by Members of Division of Mines.—Assay Plant.—Plans for the Summer. — Third Annual Bulletin of the Mineral Resources.

The question of work by members of the Division of Mines on private and semi-private undertakings has come up at numerous intervals in the past, and Warren D. Smith, Chief of the Division, has recently given out a statement substantially as below: "Private engineers will undoubtedly in time become established here, and they should be given every opportunity to do a remunerative business. It is not our purpose to compete with private individuals. For the present, however, the Division of Mines will continue in part, at least, its practice of doing work for private individuals; but such work will only be undertaken

Breaking Rock, San Mauricio.

when it is not possible for the persons desiring it to obtain competent private persons within a reasonable time, to do it for them, and therefore the following scale of charges to be paid to the Bureau of Science as Government business has been decided on. For a geological or engineering report which is confidential and which becomes the property of the person or persons requesting the work, the charge should be ₱30 per day and all expenses. If the Bureau of Science be allowed to have access to the information gained to publish it as new work, it would be proper to share the expenses, the person requesting the work paying the transportations and per diem and all costs of the expedition, with a charge of ₱5 per day for each member, which would in part reimburse the Bureau for the inconvenience. The Government will pay the salaries of the men so employed and furnish all equipment. For private work which does not involve a confidential report or responsibility, where the officer is assisting, for instance, some other engineer in surveying, mining, or sampling, the charge should be ₱10 per day and expenses. All preparations of maps, drafting, etc., are charged according to the labor involved and are extra."

Demands for information on certain districts are con-

stantly coming to the Division of Mines. At times the giving out of such information might involve injustice to those engaged in operations in the district in question. The statement is frequently made that it is desired to put such information into a prospectus for the purpose of raising capital. For this reason the Division of Mines has undertaken the publishing of the Press Bulletin to give information as promptly as possible in regard to the districts which have been visited by the members of the Division. Beginning with the next fiscal year, the Division of Mines will assume entire charge of the assay plant of the Bureau of Science. Paul Fanning, a metallurgist of experience in the United States, and in the Philippine Islands, will be in charge. The assay plant will be enlarged and new apparatus installed so that large orders can be handled promptly. The same regulations regarding the information resulting from assays will hold in the future as now. The Division of Mines will continue to make free assays from new distircts when the requests are accompanied by a reasonable amount of data that may be used for general information. Where an assay is paid for, the information is held strictly confidential.

The field work of the Division of Mines for the next few months will be as follows: A completion of the Benguet work begun in 1906 by A. J. Eveland. This work will be carried on by Mr. Smith personally, assisted by F. T. Eddingfield, mining engineer, and H. G. Ferguson, geologist. The map published in 1906 will be revised in the new light and a complete study of the ore deposits will be made. The map will be extended to the west and north if funds are available for topographic work. Later the work begun by Mr. Eveland in 1904 in the Mancayon-Suyoc district will be carried farther. This work will be done by Mr. Smith and Mr. Eddingfield. Beginning with the first of April, Mr. G. I. Adams, assisted by Mr. Pratt, will continue the general geological reconnaissance of southwestern Luzon, particularly in the Tayabas peninsula, provinces of Albay and Ambos Camarines. This work will extend over several months. Particular attention will be given to the Paracale and Mambulao districts, as a base map of those districts is now almost completed. The reconnaissance of the Sierra Madre range, northeastern Luzon, has been postponed until the return of Mr. Ferguson from the United States.

The material for the Third Annual Bulletin of the Mineral Resources is almost ready for the press. The Bulletin this year will contain a number of new features, among them being special articles on the different districts with maps; an article on the forest conditions in the Aroroy mining district by Mr. Whitford, of the Bureau of Forestry; a translation of Abella's report on the auriferous deposits of Misamis, Mindanao; a geological map of the Philippine Islands; a special article on cyanide practice in the Philippines by C. M. Eye, formerly superintendent of the Benguet Consolidated Mining Co.; and an abstract of the mining laws. It is hoped that this Bulletin will be published before the first of May.

SALT LAKE, UTAH

Tintic District.—Chief Consolidated Plans.—Eagle & Bluebell.—Centennial-Eureka.—Eureka Hill.—Grand Central.

The Chief Consolidated Mining Co., organized in February, 1909, by Walter Fitch and associates, is one of the important properties in the Tintic district. Its holdings comprise eight claims on the north slope of the range, overlooking Eureka, and in addition to this includes the mineral rights to most of the lots underlying the town. The area between the town of Eureka and the base of the mountain is known as Poverty Flat. The original development thereon was done by those formerly in control of the Little Chief, who sank a 1000-ft. shaft, and from it ran drifts westerly but found little or no ore. Mr. Fitch secured control of the Little Chief ground and soon thereafter acquired other adjoining claims, making up the present group. A cross-cut, driven easterly from the 1000-ft. station, opened the north-south ore-zone, though some of the veins on that level proved to have been partly leached. The shaft was then sunk to 1400 ft. in depth, and from that station a cross-cut was driven east, resulting in finding several veins of ore, important shoots, and chimneys occurring at the intersections of these north-south veins with cross-fissures. The orebodies here are not wide, but the ore therein is of good grade. The shaft was now sunk to the depth of 1775 ft., a cross-cut was run to the ore from the 1600-ft. station, and a drift of considerable length was driven on the orebodies. The work of making a raise from the 1600 to the 1400-ft. level has been commenced. The ore encountered in this raise is supposed to be on one of the same shoots as was opened on the 1400-ft. level. The plan is to sink to 1800 ft. and from that point follow the ore zone into the territory under the town where mineral rights have been obtained. The limestone of this part of the district is overlain by strata of rhyolite which is from 300 to 500 ft. thick. Present development indicates that there are numerous cross-fissures intersecting the mineralized zone. The ore is said to contain about 70 to 87% silica, and carry very little oxidized iron. It runs about $2 gold and 60 oz. silver per ton. This valuation is based upon the returns from shipments of 3000 tons since Mr. Fitch assumed control, the net proceeds of which were $62,000. The silver occurs as ruby and native. The holdings are estimated to cover 4000 ft. on the strike of the mineralized zone. In order to acquire the mineral rights from lot owners, the Eureka City M. Co. was organized with 1,000,000 shares. Of this the Chief Consolidated took 510,000 shares, and agreed to supply a development fund up to $100,000; the balance of the shares were used to exchange to lot owners for their mineral rights. Later the Chief Con. absorbed nearly all the outstanding shares of the Eureka City M. Co. by exchanging its own shares therefor. Thus, all lot owners who gave quit-claims to their mineral rights now hold shares in the Chief Con. M. Co. in lieu of same. In anticipation of more aggressive work, the company has ordered a double-drum steam-hoist of Wellman-Seaver-Morgan Co., some additional boilers, and contemplates the purchase of a new air-compressor having the capacity of 2200 cu. ft. of free air per minute. In the meantime the 2-compartment shaft will be enlarged to 3-compartment.

The Eagle & Bluebell mine, lying southwest from the Chief Con. group, is shipping 16 to 18 cars of ore per month, which runs 0.17 to 0.71 oz. gold, 16 to 20 oz. silver, and 10 to 40% lead. One shipment of 100 tons netted $3593; another of 51 tons brought $1977 net. The mine is now worked through a 1200-ft. adit, at the farther end of which is an 1100-ft. interior shaft in which the ore is hoisted by compressed air. The ore-zone is entered by a 1200-ft. drift north from the 1000-ft. station, the ore occurring on this zone in parallel lenses. Close to the face of the 1200-ft. drift a winze has been sunk 200 ft. in the ore. A cross-cut is to be driven about 250 ft. from the vein on the 1000-ft. level to reach a point exactly below the old 200-ft. shaft, which is to be sunk to the level of the cross-cut. This will afford more direct connection between the main workings and the surface and make more economical mining. Imer Pett, manager for the company, states that a new steam-hoist is to be installed at the collar of the shaft.

The Centennial-Eureka and the Bullion-Beck, both properties of the United States S. R. & M. Co., operate under the general superintendency of C. E. Allen, with R. A. Brown in direct charge of the former, and L. C. Doty of the latter. The Bullion-Beck, with 30 men on the pay-roll, is mining at the 300, 400, and 500-ft. levels on a new ore-zone, parallel to the strike of the old orebodies, and 250 ft. west from them. This ore has been opened a distance of 400 ft. on the fourth level, its width ranging from 8 to 10 ft. A 100-ton shipment is said to have sampled 6% copper, 1 oz. gold, and 15 oz. silver. Several lessees are mining in the old workings and producing about 200 tons per month of fair-grade ore. The Holden tunnel, which starts at a place 1500 ft. west of the Bullion-Beck shaft and 70 ft. below it, runs 2200 ft. southwest into Centennial-Eureka ground, connecting with the shaft on the latter property at the 600-ft. station. The portal of this tunnel is about on a level with the railroad, and eventually all ore mined at the Centennial-Eureka will be hoisted only to the

600-ft. station and then hauled out through the tunnel by electric locomotives. A power plant is being installed close to the tunnel's portal, to consist of steam boilers, engines, and electric generators, all of which are being housed in a steel building. The Centennial-Eureka management is having a pump station cut out at the 2200-ft. point in the shaft, which is water-level.

The Eureka Hill mine, of which George W. Riter is manager, has 24 sets of lessees at work, who ship an average of 500 tons of ore per month, some ore being taken from all levels from the surface to the 1000-ft. level, the work being in the nature of a cleaning up process. The ore contains gold, silver, copper, and lead, some of it very high grade, and of many varieties. The lead occurs as carbonate and steel galena; the silver as bromide, sulphide, and chloride; the copper as malachite, azurite, tetrahedrite, and native. Charles Baker, superintendent for the company, states that while there are but 27 acres of surface in the holdings, there are 30 miles of workings. All leases run three months, subject to renewal at the end of that term. Royalties paid by lessees range from 20 to 50%, the sliding scale being according to the grade of the ore. It is said most of the men make sums far better than ordinary wages. On this property is a tailing dump said to contain 250,000 tons, which accumulated during the years that the concentration and pan-amalgamation mill operated. It is supposed to contain 6 oz. silver, 80c. gold, 1½% lead, and 0.2% copper.

The Grand Central, situated on the Mammoth side, opposite the Centennial-Eureka, shipped 1400 tons of ore in April, which ran $3 gold, 30 oz. silver per ton, 4% copper, and 10% lead. This ore was taken from all levels from the 600 to the 2100-ft., inclusive.

NEW YORK

Copper Producers' Figures.— Anaconda and Porphyry Coppers.— Ray Central. — Cobalt and Silver. — Heinze Acquitted. — Nevada Con. and Associated Oil Listed.

The report of the Copper Producers' Association covering the month of April was expected to show a considerable accumulation. Exports for the month were known to have been light. It was with a good deal of pleasure, therefore, that an increased consumption was noted. It has been borne in upon that part of the public interested in copper shares and in the copper metal market that the producers are not in harmony, at least, not in any such close degree of harmony as is necessary to put in force the drastic curtailment which would rescue the copper metal market from its present plight. The copper situation is much like the old story of the boy, who yoked himself with a calf, which promptly ran away, accompanied by loud cries, from the lad, of "stop us, somebody, stop us." Curtailment is the real economic remedy; all the producers are in favor of curtailment—if the other fellow does the curtailing; in the meantime dividends, interest, and depreciation charges must be earned on immense plants, and those who would stop cannot. Since, therefore, it is recognized that the output cannot be reduced, it is gratifying to note an increase in consumption. Domestic deliveries for April were 67,985,951 lb., an increase over the preceding month of 5,141,133, and the heaviest demand since the month of January, when domestic consumption accounted for 78,158,387 lb. Export deliveries, on the other hand, show a decrease of 9,253,364 lb., the total sent abroad amounting to but 31,332,403. This comparatively poor showing in the way of export demand is discounted, however, by the knowledge that some heavy shipments are to be made during the current month, and the further fact that the visible supply of red metal abroad has decreased, though such decrease is not as large as it should be if the demand were up to normal.

The increase in copper surplus for April is 18,159,285 lb. Production for the month was 117,477,639, accumulated stocks total 141,984,159. One large copper producer reports sales of 20,000,000 lb. at 12½c. for delivery during the next ninety days, while the Butte output is reported as sold up to the first of June. It is evident that the Amalgamated-Anaconda situation holds some possibilities which must be reckoned with. Amalgamated owned a short time since, when balance sheets were published, some 3,075,000 shares of Anaconda, or almost exactly two shares Anaconda for every share of Amalgamated outstanding. Amalgamated owns its timber lands and 100,000 shares of Greene-Cananea in addition to its Anaconda. Nevertheless, the sale of 200 Anaconda shares against the purchase of 100 Amalgamated would show a profit of $1750. The new Anaconda is, of course, to feel the pressure of cheap copper. The porphyries are in the lead, a little unwillingly, perhaps, just at the moment, but in the lead nevertheless, and it is an open question as to the opposition they are to encounter. The leading group of steam-shovel properties, Utah, Ray, Gila, Chino, and a half interest in Nevada Consolidated, are closely allied to the Guggenheims and the A. S. & R. Co. The International S. & R. Co. is distinctly a Cole-Ryan-Amalgamated enterprise, and it is not to be believed that this concern is to be absorbed by the Guggenheims or is to be a non-aggressive competitor. It is quite true that if forced to do so Anaconda could meet the situation in Butte by doing what was done before, taking out only high-grade ore, and so cutting copper costs to a five-cent basis, but this policy is something of a desperate one, and the entry of the Amalgamated interests into the field of porphyry coppers is more logically to be expected. In any event there are signs of alignment for a bitter struggle in which the only complacent figure will be the consumer, who is perfectly willing to have cheap copper and to let the producer carry it for him. The figures for the quarter ending March 31 showing the production of the porphyries indicate how fully they control the situation; Utah Copper produced 18,511,819 lb., which was sold at an average of 13½c., and which cost to produce 8.43c. per pound; the net profit for the quarter was $871,958. This production is an increase of 3,000,000 lb. over the best quarter preceding, and, as operations on the Boston Con. ground are followed up, further increases in output are to be expected. Nevada Con.'s output for the like quarter was 13,528,647 lb., while the net surplus, after the dividends were paid, was $80,562, as against a deficit for the previous quarter of $33,602. It is just exactly this situation which forces the production of millions of pounds of copper, and the payment of all the net earnings in dividends, which cries for regulation. That a huge producer such as Nevada Con. should show a deficit one quarter and a bare margin for surplus the next, means great waste. Huge production, involving much capital, and a return of but $1.50 annually upon an investment of $20, or at the rate of 7½%, without any buttressing of the investment by a growing surplus, demonstrates that, like the boy and the calf, some of the big new coppers have 'got going and can't stop'. J. Parke Channing, who has been expected to make some kind of a statement in reference to Ray Central, was before the directors at a meeting held this week in New York, and went quite fully into the recent developments at the property. Mr. Channing stated that there was satisfactory progress being made in the matter of ore development, but presented no estimate of tonnage. Some 6% copper ore is stated to have been developed in a winze between the 300 and 400-ft. levels. A 1000-ton mill is planned.

While the price of silver has been advancing, it has caused no revival of interest in Cobalt. Cobalt has been outstripping previous records in the matter of shipments. In many of the more important properties a better showing is possible in the way of ore reserves than at any time in the history of the camp, yet the attention of the Canadian prospectors and the Canadian public is centered in Porcupine. The first actual test of the new camp has been made, with results that justify the boom the district has so far had. Before the winter roads broke up the Timmins people, working what is locally known as the Hollinger property, got a carload of ore out to the railroad. Part of this was sent to the School of Mines at Kingston and part of it went to the refinery at Perth Amboy, New Jersey. The shipment is said to have been made without any sorting of ore, and the returns just made public show an average value of $202.75 per ton. The result of this first real return for Porcupine is a wave of renewed activity and a

general stiffening of prices for claims and options. In Cobalt an interesting new project is being discussed. Proper prospecting in Cobalt has always been at heavy expense by reason of the deadfall and overburden which could not be removed but must be cut through by trenches. Now it is proposed to profit by the work of the hydraulic engineer and install giants to wash the face of Cobalt so that such silver sidewalks and vein 49s as may be hidden under the surface may be revealed. There are several details that must be worked out before the scheme becomes at all possible. Consolidations, or working agreements at least, are necessary to prevent trouble on account of the piling of débris. If this and other matters can be arranged it would seem logical that such work might greatly increase the known mineral wealth of Cobalt.

F. Augustus Heinze was acquitted of the charges upon which he has been on trial for the past two weeks in the Federal Court in New York. The real verdict was to the effect that bad banking is not necessarily a crime. United Copper, one of the mysteries of the copper market, was much in evidence, but out of all the mass of testimony in relation thereto nothing has come to really enlighten the present shareholders as to the assets and liabilities of the company. It is said that the Santa Brigida, near Ocampo, Chihuahua, Mexico, is to be examined by engineers for Thomas F. Cole, who has taken an option on the property in behalf of the Sierra Con. M. Co., which latter organization is controlled by Mr. Cole and Joseph B. Cotton. The Santa Brigida was largely developed by W. C. Greene and is now owned by Norval J. Welsh, of San Antonio, Texas. The Sierra Con. M. Co. is an organization which took over most of the properties of any merit that were controlled by the now defunct Greene Gold-Silver company. John B. Hastings expects to begin work soon overhauling the mill and getting in shape for active operations on the Yellow Jacket property in Lemhi county, Nevada. This property was originally owned by John E. Searles of the American Sugar Refining Co., and by reason of legal complications connected with the settlement of the Searles estate has laid idle until recently taken over by the Proprietary Mines Company of America. The shares of the Nevada Con. Copper Co. have been listed on the New York Stock Exchange. This listing of the stock of the Associated Oil Co. of California by the committee of the New York Stock Exchange has added an impetus to the growing interest throughout the East in oil properties; the tremendous dividends which have been turned back to stockholders on their investments in oil properties in California and the great enthusiasm in oils, which is coincident with the rubber boom in London, are beginning to have effect here, and it will be strange if there is not something of an oil craze here in the near future.

BUTTE, MONTANA

Butte Mines and Copper Costs.—Clark Properties Sold.— Miscellaneous Development.

The talk in Eastern publications of the probable necessity of Butte mines shutting down or curtailing production on account of the increasing copper surplus and falling prices of the metal is far off the mark. Amalgamated authorities say that Butte mines will be turning out copper when many others that are now producing are forgotten. Merging the Butte mines will reduce the cost of production to a point where they can profitably compete. That, together with the high silver and gold content of the Butte ores, will make copper mining in Butte profitable when copper is much lower than it has yet been quoted. When copper sold at 9c. per pound the Butte mines made money, and they can do it again. The production of the district is, in fact, gradually increasing. Not only are all the old mines, with the exception of the Parrot, producing normally, but several new producers have been added to the list. The Butte-Ballaklava Copper Co. has begun regular daily shipments of 300 tons of ore to the East Butte smelter, and is producing copper at a cost under 8c. per pound. Official announcement is made of intention to pay the first quarterly dividend in July.

The sale of the Clark copper properties in the Butte district to the Amalgamated Copper Co., which was announced in these letters a month ago as being under negotiation, has been consummated and officially confirmed. These properties have been producing from 1,000,000 to 1,500,000 lb. of copper per month. An official statement issued from Mr. Clark's Butte office says: "The sale is of the Original Consolidated Mining Co.'s property, which includes the Original and Stewart shafts, with all the copper interests immediately adjacent to them. The only other mining property involved are two small fractions lying between the Alice and Magna Charta mines, which latter already belong to the Amalgamated company. The Amalgamated company acquired the Butte reduction works, but Mr. Clark retains the use of the concentrator for a term of years, and all the shops, such as machine shop, blacksmith shop, carpenter shop, and assay office. The concentrator will be operated on zinc ores, and it is anticipated that the zinc business will develop immensely and become a very important element in the future of Butte. Work will soon be commenced on mining properties that have been lying idle for years, and it is anticipated that the change of ownership in the copper mines will in the long run tend to promote the welfare of Butte." The Tuolumne Copper Co. has become a regular shipper and is producing around a million pounds of copper each month. Everything is moving satisfactorily in Butte. The merger of the principal mines has been completed, the deal having gone through without a hitch. W. A. Clark, John D. Ryan, W. D. Thornton, and A. C. Carson have gone or are going to Europe to spend the summer. Official announcement is made that the time for exchanging Butte-Milwaukee stock for Butte-New York Copper Co. stock will expire May 31.

The new electric hoist of the Butte-Ballaklava Copper Co. is in operation and working satisfactorily. The hoist is being watched with a great deal of interest as it is the first deep-sinking electric hoist in this section. It is driven by a 300-hp. electric motor and has a capacity for sinking to 3000 ft. It can lift from 300 to 500 tons of ore per day, and in addition carry on development on a large scale. During the month of April the output of this property amounted to about 350,000 lb. of blister copper and 35,000 oz. of silver; the latter fully paying the treatment expenses. The books, records, documents of all kinds, together with the cash in the treasury amounting to some $259,000 of the Barnes-King Gold Mining Co., are now in the hands of W. H. A. Fischer and his associates in New York. Some time ago a demand was made for the records and money from the officers in this city, but the demand was refused, pending a certified copy of the directors' meeting showing that officers had been elected. This was recently received and the order was complied with. Nothing can be ascertained here as to what the new board of directors proposes. Mr. Fischer has expressed himself as favorable to acquiring the North Moccasin property. The Raven company has for several months been proceeding quietly with development. The shaft has been sunk to a depth of 1500 ft. and at the present time a cross-cut is being run north to intersect the vein developed above. The cross-cut is now in about 200 ft. from the shaft. On the 1500-ft. level a number of stringers have been cut and some good ore found. The Radersburg Consolidated Mining Co., which recently took over the Ohio-Keating, is likely soon to add the Dew Drop group of claims adjoining the Ohio on the northeast and group of three claims lying about 1000 ft. south of the Black Friday property. The Black Friday is reported to have opened a body of ore at 450 ft. Ore taken out recently averaged about $50 net per ton. Good progress is being made in installing the electrical equipment of the Keating Gold Mining company, and the surface plant on the Blacker claim should be in operation early this month.

It is expected that mining will be commenced at the Ophir mine of the Butte Central Copper Co. about July 1. Three boilers with a combined capacity of 330 hp. are now being set. Between five and six weeks will be required to unwater the mine. A new compressor is to be installed and will be in readiness for operation when the water has been taken out.

General Mining News

ARIZONA

COCHISE COUNTY

(Special Correspondence).—The Eagles' Nest group in the Paradise district has been re-christened the Solwico, and a company will be formed to further develop the property. M. R. LaRue, of Paradise, is one of the owners of the ground.——The vein in the face of the drift on the 120-ft. level is now about 2 ft. wide and assays from 3 to 4% copper.——The shaft at the Scott & Crawford is now down 45 ft. in the limestone and is expected to open the ore in a short distance.——The shaft at the Nippers property of Otto Duffner is down 30 ft. and has opened a vein of lead-silver-copper ore.——The Virtue company is driving a 1000-ft. adit that will tap the vein at a vertical depth of 700 ft. when completed.——Bisbee capitalists are operating the Leadville group under bond and have made several shipments of lead ore.

Bisbee, May 14.

The Employees' Benefit Association, one of the philanthropic institutions of the Copper Queen, inaugurated on January 1 last, has rendered its report for February. The members' contributions yielded $3800, being at the rate of 2% of the wages of the employees. Death benefits paid were two, one being on account of death from pneumonia, yielding to the heirs $1277, or one year's wages, and the other being for death from accident in the converter plant, the insurance paid amounting to the equivalent of two years' wages, or $2555. Total payments of benefits for

Miami Mill Under Construction.

February reached $5223. The total number of members at the beginning of February was 2067. Membership is voluntary, but admission is now conditioned by age and medical examination. Those registering for admission at the time when the association was organized on January 1, 1910, were accepted regardless of age or condition of health, the only requirement being that they were enrolled among the employees of the Copper Queen. The company contributes $2000 per month to the fund.

GILA COUNTY

(Special Correspondence).—As the 420-ft. haulage level at the Miami mine has been virtually completed, the second haulage level at a depth of 570 ft. is being established, a drift from the No. 4 shaft toward the orebody having already been started. The steel frame of the concentrator is nearly finished and some parts of the interior equipment have arrived. Nearly all the machinery for the power-house and new hoisting plant is at hand. On the Captain claim, the twelfth churn-drill hole is being sunk.——Drill-hole No. 2, which is 300 ft. west of the vertical shaft on the Live Oak property, has just passed into chalcocite ore at a depth of 232 ft.——The Warrior mine is continuing shipments at the rate of 90 tons per day of 9.5% ore. The churn-drill hole being sunk on the Winnie claim has penetrated schist at the depth of 300 ft.——The Little Miami Mines Co. is installing a 25-hp. gasoline hoist, preparatory to sinking a 2-compartment shaft on its property, which is situated between the holdings of the Miami and Warrior companies. Richard Fleming, of Globe, is general manager.

Globe, May 13.

The orebody opened recently 1200 ft. west of the main shaft of the Old Dominion mine is proving to contain first-class ore. The company has just received its steam turbines and generating equipment for the installation of the smelter power-plant and is installing the new machinery. The management is now considering the installation of an electric haulage system on the 12th and 14th levels of the A shaft. Three of the large Nordberg pumps installed on the 12th level have been running for over a month and the fourth will be in operation in a few days.

MOHAVE COUNTY

The Needles Mining & Smelting Co. expects to blow in the smelter at Needles about July 1 and will have the concentrator in operation shortly after that date. The two plants will cost in the neighborhood of a million dollars. Custom ore is now coming in and all offered is being purchased.——The drift on the 100-ft. level of the C. O. D. mine has opened 12 in. of high-grade lead-silver ore.——The Los Angeles Gem Co., which is operating the George Washington mine in the Mineral Park district under bond, has opened 2 ft. of gold-copper ore assaying $238 per ton in the drift that is being driven to develop the vein.——At the Home Pastime mine, which Joe Prisk and Charles Perdue have been working on a lease for two years, a 7-ft. body of milling ore with one foot of high-grade has been opened.——The old Mexican mine, one of the best of the early producers, has been bonded to A. M. and A. H. Smith. New machinery will be installed at once and development started.

PIMA COUNTY

The Cerro-Colorado Mines Co. has purchased the Cerro-Colorado mine in the southern part of the county from Hugo J. Donau and will commence work on the property at once. The group was first worked in the early sixties and is now equipped with a good hoist, compressor, and electric lighting plant, but the distance from the railroad made the expense of working excessive and it was not considered a profitable venture until the Tucson & West Coast of Mexico railroad was completed.

YAVAPAI COUNTY

(Special Correspondence).—It is reported that the Great Republic Copper & Gold Mining Co., owning properties in the Bradshaw mountains, are preparing to resume active work on the group. About 3000 ft. of development has been done, including one double-compartment shaft 726 ft. deep.——The Haynes Copper Co., at Jerome, has completed the unwatering of its property and is working three shifts with 30 miners.——J. J. Fisher, manager for the United Verde Extension Mining Co., reports that the recent discovery in the Little Daisy property continues high grade.——The bunk-house of the Speck Mining Co., on Lynx creek, was destroyed a few days ago by fire.

Prescott, May 14.

Wires from the main line have been strung to the property of the Mount Elliott Consolidated Mines Co. in the Big Bug district and connections made with the new hoist at the Ticonderoga shaft. At the 200-ft. level cross-cuts are being driven to tap the Ticonderoga No. 2 and Independence veins both of which have good outcrops. Ten additional stamps are being installed in the mill and ten more will be installed in the near future.——The United Verde Copper Co., at Jerome, recently blew in a new furnace which makes the fifth now in action in the great copper works.——The 2-stamp Nissen mill which the Midnight Test Mining Co. recently purchased has been erected at the property south of Prescott and is now running successfully. It is estimated that there are 1000 tons of ore on the dump which will keep the mill busy till the shaft is unwatered and timbered to the 100-ft. level. If the work proves satisfactory the company will increase the milling capacity of the plant and add concentrating tables. G. S. Alstead is manager.——The adit of the Pacific Copper Mining Co. cut a body of sulphide ore when in 400 ft. The property is situated in the Silver Mountain district four miles south of Harrington and adjoins the Monte Carlo mine.——The assay office

and laboratory at the Humboldt smelter was completely destroyed by fire last week. The loss is estimated at $25,000 which is partly covered by insurance.

YUMA COUNTY

Llewellyn Humphreys, W. H. Clark, and associates of Salt Lake have acquired control of the Silent King group of mineral claims in the Alamo mining district, 40 miles south of Vicksburg and 55 miles north of Mohawk. The claims cover a strong cropping of quartz-porphyry, a representative number of samples from which assayed an average of $1.50 per ton in gold. Mr. Humphreys spent some time there recently and reports having put on a small force of men to do exploration and development work. The group is situated between the Plumas and Eagle Tail mountains. The ore seems to be favorable to cyanidation. The operation of the Parker branch of the Santa Fe railroad is having the effect of advancing mining development in this part of Yuma county.——The North Star mine and mill, at Polaris, are operating successfully with a force of 100 men, the mine workings extending to a depth of 500 ft. The property has a vein of medium-grade gold ore; the milling process consists of roll-crushing and cyaniding.——The King of Arizona, at Kofa, has not been in operation since January last, but it is reported that operations may be started again before long.

CALIFORNIA

AMADOR COUNTY

J. M. McDonald has filed an attachment for $112,947 against the California Consolidated Mines Co. which amount is due on the bond that the company held on the Keystone mine near Sutter Creek. The company secured a number of claims in this district about three years ago but has failed to raise sufficient money to meet the payments and has been attached by several firms.

CALAVERAS COUNTY

The shaft of the Ball Mountain Co. has cut the blue gravel of the old Vallecita channel at a depth of 540 ft. The company so far has not been bothered with an excessive flow of water and will sink through the gravel to the bedrock. Water is to be brought from the Union Construction Co.'s ditch, a distance of 1200 ft., to the property and the work of sluicing the gravel started at once.

NEVADA COUNTY

A creosote plant consisting of two 16-ft. tanks is to be installed at the Empire mine near Grass Valley. The solution will be heated by circular coils and the timbers each given two treatments.——The unwatering of the Canada Hill mine has been completed and a new compressor ordered which will be installed within the next few weeks.——The bond on the Oustomah mine which Mrs. Minnie Mundy has held for the past 18 months has been given up and operations, except pumping, suspended at the mine. The Oustomah Gold Mining Co., which owns the property, has brought suit to recover $18,000 that it claims is due as royalties from E. O. and J. O. Hayes who formerly had a lease on the mine.——The adit at the Black Bear mine, at Moore's Flat, cut a vein of high-grade ore much of which shows free gold, and picked samples have assayed as high as $1000 per ton. The McKinley vein has been crossed and average samples, taken across the width of the ore, milled $10 per ton. C. L. Wilson is one of the main owners and it is the intention to erect a mill on the property this summer.

PLUMAS COUNTY

(Special Correspondence).—The Bushman placer claims, where a fair grade of gravel has been opened, has been taken under bond by Pennsylvania capitalists.——E. Arundell Smith, an English mining engineer, has taken a bond on the Golf Leaf group of quartz claims in the Argentine district. The stated purchase price is $12,000. The bonder has leased the Crown Point mill and states that development will be started at once.——The White Lily is keeping six stamps in operation and working a force of men on the main vein, which, in places is 60 ft. wide. Sterling P. Dunn is manager.——The Seneca Development Co. is driving an adit to intersect the gravel deposits in the Sunnyside mine.——The Walker Mining Co. is developing an excellent body of copper ore in the Genessee district. The lode is over 50 ft. wide and assays 4 to 25% copper, in addition to gold and silver value approximating $5 per ton.——The Engle Copper Co. is rapidly completing its 100-ton smelting plant in Light's canyon.——The Genessee Valley Copper Co. has a force of men at work on promising deposits. W. G. Lummis is superintendent.——The Mountain Meadow Co. expects to resume operations before the end of summer.——It is reported that rich ore has been uncovered in the Hinchman mine.——Two monitors are in operation at the Neoscene placer mines at Scales, and large restraining dams have been completed to prevent the escape of débris to the river.——The Supervisors have decided to construct a wagon-road from Mohawk valley to connect with the road building to the Gold Lake section. This will greatly facilitate mining in the southern portion of Plumas county.

Quincy, May 14.

SHASTA COUNTY

The iron smelter at Heroult is again running and turning out about 20 tons of pig iron per day.——The foundation of the bag-house at the Kennett smelter has been completed and the superstructure is well under way.——Seventy-five members of the Shasta County Farmers' Protective Association have signed the smoke agreement with the Balaklala Copper Co. ratifying the agreement made by the executive committee.——There are 20 men working at the Gold Leaf mine, on Salt creek, and the ore is being shipped to the smelter at Kennett. The Brackett property, in the same district, is also shipping to the smelter.

SIERRA COUNTY.

A new company has been organized to re-open the old Phoenix mine at Sierra City and work has been started re-building three miles of flume that will carry water to the mine for power and for the mill.——The adit at the Queen Radigunde mine, in the Alleghany district, opened an 18-in. vein of high-grade ore.——A mining car and a consignment of rail have been shipped to Downieville for the Sierra-Poorman mine, and will be packed to the mine as soon as they reach town.——The mill at the Omega drift mine is being run one shift per day, and from 20 to 25 tons of gravel crushed that assays about $3 per ton.——The channel has been cut in the South Fork mine at Forest which the Rio Antigua Mining Co. is operating under bond. The gravel was opened on the west rim and an incline has been started to tap the bottom of the channel.

TUOLUMNE COUNTY

(Special Correspondence).—Operations have been resumed at the Gold Ship Mining Co.'s gravel claims in the Groveland district. Drifting is in progress and the main shaft is to be sunk to bedrock. A transmission line from the Tuolumne Electric Co.'s plant, three miles distant, is contemplated.——Work is to be resumed at the Mary Ellen mine, situated near the Mohican and owned by A. B. Cruickshank, of London.——The Karnac Mining Co., whose property is west of Jamestown, contemplates the erection of a 10-stamp mill in the near future. The Hancock shaft has attained a depth of more than 100 ft. and will be sunk 150 ft. before cross-cutting.——A small crew of men is employed at the Clio mine, recently bonded to Salt Lake interests.——A new boiler has been installed at the Mangante mine, near Jamestown, and a four-drill compressor purchased.

Tuolumne, May 16.

The Carlow-Hensley Co. is prospecting the old James Wickman mine, near Tuttletown, upon which it has secured a bond.——There are 200 tons of ore that averages $50 per ton on the dump of the Champion mine which will be crushed in the plant of the Penon Blanco as soon as the Standard Electric Co. completes its line to the mill.——It is reported that operations are to be resumed at the Mary Ellen property on the Tuolumne river.——An 8-hp. gasoline engine has been ordered for the Chilano mine near Tuttletown, and will be installed to drive the 3-stamp mill on the property which is being operated under bond by W. T. Watson.——The bedrock adit at the Haslam placer claim

is now in 200 ft., and the operators, W. H. Buthenuth and Clarence Haslam, are washing a good grade of gravel.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—The shaft at the Bruce mine is to be unwatered and retimbered from the 125-ft. level, at which time drifts will be started from the various levels. C. L. Jaynes is manager.——J. J. May, who has been awarded the contract for driving the Lucania adit 500 ft., started work last week. Power for the operation of machine-drills will be secured from the Hoosac plant. The adit is now in 4209 ft.——It is stated by W. E. Malm, in charge of construction of the Malm chemical-electro plant at Georgetown, that the mill will be ready to begin ore treatment by July 1. The heaviest of the machinery has arrived and the balance, consisting of electrical equipment, has been shipped from New York.——A body of smelting ore 4 ft. wide has been opened in a stope on the Aetna vein of the Capital mines. From a shipment of one carload that was made a few days ago returns of 4 oz. in gold and 40% in lead were realized. W. N. Brady is the new manager.

Idaho Springs, May 14.

GILPIN COUNTY

(Special Correspondence).—A hoist and small compressor have just been installed at the Sea Bird property in the Northern district and a winze is now being sunk from the adit-level.——Grading has been started for the new mill to be constructed by the Golden Sun Mining & Milling Co., on South Boulder creek.——The shaft on the War Dance mine, down 330 ft., is to be sunk another 100 ft. Shipments from the east drift on the 280-ft. level are being settled for at the rate of 20 oz. gold per ton.——The 500-ft. shaft on the Chase mine is being sunk an additional 100 ft., work having been put under way last week.

Central City, May 13.

LAKE COUNTY

One of the steadiest producers on Breece hill, in the Leadville district, is the Penn property which is being operated by three sets of lessees.——The new work that was started at the old Gallagher mine last year is again being advanced and the north drift is being driven to open an orebody that is known to lie in this direction.——Thomas Gilroy has commenced work on the Galesburg and Free America claims and is sinking a shaft to prospect the vein.——A number of local operators have secured a lease on the Robert Emmet mine which is one of the oldest in the district and will open the old stopes to recover the low-grade ore left there in early days.——Work has been started on the Famous shaft in South Evans gulch by G. S. Schroeder who recently secured a lease on the property.——The breast of the Yak tunnel has now reached the lateral work of the Diamond mine and the workings are being drained. The water will soon be out of the old stopes of the Resurrection which has also been tapped, and the lower levels of the property re-opened. The present work is being carried on by the company though there are a number of lessees shipping ore from the stopes above the water-level.

SAN MIGUEL COUNTY

Work has been resumed on the Paradise group on South Lookout mountain in the Ophir district. Over 600 ft. of development work has been done on the property opening a vein of gold-lead-silver ore that is worth from $40 to $50 per ton.——The first payment of $20,000 has been made on the Favorite property which was purchased last fall for $60,000. There are 20 stamps dropping in the mill where the ore is concentrated in the ratio of 6 to 1, which has a value of about $85 per ton.——At the Wealth of Ophir mine a shoot has been opened that assays $20 gold and 100 oz. silver per ton.——Work for the season has been started on the property of the Trilby Gold Mining & Milling Co., in the Silverton district, which is under lease to the Danville Mining & Leasing Co., and ore shipments will be started early in the season. The company has been operating the group for the past two years and has opened a good grade of copper ore which contains some gold and silver with a small amount of lead.

SUMMIT COUNTY

Work has been resumed at the property of the Iowa-Nebraska Mining Co., in the Frisco district, and the adit is being advanced to cut several veins whose outcrops have been traced on the surface of the claims. At present the work is being carried on by hand, but it is the intention of the company to install a compressor and drills some time this summer.——New sluice boxes and a flume have been put in at the Bodege placer claim and operations resumed for the season.——At the King Solomon the west drift on No. 11 vein has opened some loose ground and progress has been slower than usual on account of having to timber the workings. The company has just installed a new ventilating fan.

TELLER COUNTY

Lessees of the Joe Dandy mine, in the Cripple Creek district, recently shipped two carloads of high-grade ore which included approximately six tons of sacked ore that assayed $1000 per ton.——Fred Shaefer and associates, operating a sub-lease on the Anchoria-Leland property on Gold hill, cut a 4-ft. shoot of milling ore.——The quarterly report of the Doctor-Jack Pot Mining Co. recently mailed to the stockholders states that the average of the ore shipped during that period was $24.40 per ton, a value slightly above the general average of the district, and the royalties amounted to $5750. The Lucky Corner Leasing Co. continues to be the largest shipper, sending out about 500 tons per month.——Twenty-one sets of lessees are active in the Gold Dollar Consolidated properties according to the report mailed to the stockholders by the manager H. L. Sheperd and have paid into the company's treasury $20,870 in royalties during the past year.——L. A. Van Tilborg and associates have opened a 4-ft. shoot on the 250-ft. level of the Bison property of the Free Coinage company and are shipping material that averages $30 per ton.——The Mitchell mine, on Bull hill, has been brought back to the shipping class by the Pinnacle Mining, Milling & Leasing Co., which has opened several stopes on the 350-ft. level.

IDAHO

IDAHO COUNTY

The Center Star mine, north of Elk City, has been sold to New York interests for $100,000, and the first payment of $5000 has been made. The bond calls for another payment of $5000 at the end of three months, and the final payment of $90,000 at the end of a year.——George Jennings has secured a bond on the Red Horse placer claims and the Hope quartz group on Red Horse creek, three miles from Elk City, and has commenced work for the season. The placer claims are fully equipped and will need no further improvement, but at the Hope group a whim will probably be installed and a shaft started on the vein.——Work has been resumed on the Buckhorn group in the Four Mile district where a 21-ft. vein of free-milling ore has been opened. Samples from the face of the drift, which is in 210 ft., have assayed between $15 and $20 per ton.

KANSAS

CHEROKEE COUNTY

(Special Correspondence).—Among the new mills built in the Galena camp is the 200-ton plant on the O'Neil land at Riceville which will be started in the next fortnight.——The Nowata company is planning the erection of two large mills on the Luscombe-McElroy leases. It has just installed large centrifugal pumps to drain the ground, which has laid idle for a long time.——Thacker & Campbell have taken a lease on the Neal land, which is in the centre of a rich district, from the Galena Lead & Zinc Co., at Galena. Machinery will be installed at both shafts, one of which opens a working face 180 ft. long and 12 ft. high.——The Lizzie D. mill has been bought by the Diplomat company and will be removed from the Badger camp to the Diplomat lease in the Galena field. There are three shafts on this ground, all in good ore.——The Omaha-Petersburg company in the Baxter Springs camp has closed a contract for the erection of a large mill on its lease. A mill built on the plan of the Eastman, with a complete sizing system and having a capacity of 500 tons, will be

built.——The Lolita company is pushing work on its mill and expects to have it done in a few weeks.——A rich body of lead-zinc ore was opened on the Hubbard lease at Badger. ——The Herald mine has installed new ventilating pipes to the face of the workings.

Galena, May 13.

MONTANA.

SILVER BOW COUNTY

The installation of a new electric hoist and the opening of a high-grade orebody on the 800-ft. level of the Butte-Ballakiava mine at Butte have made it possible to increase the shipments from 70 to 200 or 300 tons of ore per day. Work on the 800-ft. level for some time past has been disconraging on account of numerous faults, but recently a body of ore 18 ft. wide and assaying 10% copper, with 20 oz. silver, has been opened by the drift.

NEVADA

CHURCHILL COUNTY

(Special Correspondence).—The Nevada Hills mine and the Fairview-Eagle, at Fairview, have been consolidated and the two properties will be operated by the Nevada Hills Mining Co., with George Wingfield at its head. The original Nevada Hills has opened a fissure vein in andesite to a depth of 470 ft., and the Eagle has a parallel vein, 1000 ft. from the former vein, which has been developed to some extent. The workings of the two eventually will be connected. The ore in both veins consists of silicified andesite and quartz, containing silver and gold averaging $25 per ton, the silver constituting 75% of the total value. Silver occurs as chloride as deep as 250 ft., below which it is mostly stephanite. It has been decided to erect a stamp-mill on the property, which will be equipped with concentrators and a cyanide plant. It is believed the Nevada Hills ores will require treatment similar to that given the ores at Tonopah. W. H. Webber will probably remain in the position of manager. It is said that 300,000 shares of the new organization will be placed in the treasury. The mill to be erected is to have the capacity of about 60 tons per day, but arrangements will be such that additions can be made readily.

Fairview, May 13.

CLARK COUNTY

The cross-cut on the 400-ft. level of the Nevada Eagle mine in the Eldorado district has cut 20 ft. of ore which averages $11 per ton, and the superintendent, G. D. E. Mortimer, has gone to Denver to arrange for a milling plant. A test lot of 2½ tons of ore will be shipped for experimental treatment. The mine is dry and water will be piped from the Colorado river a little over two miles.——At the Capitol property two feet of shipping ore has been opened on the 200-ft. level which assays $25 per ton in gold besides its lead content.——The Searchlight Mining & Milling Co., which is enlarging and retimbering its shaft, has the work completed over 150 feet.

ESMERALDA COUNTY

In spite of the recent heavy loss of the Goldfield Consolidated the gross production during April was the greatest in the history of the mine and the net profit second to but one. The gross production amounted to $1,099,640, and the net profit $964,328.——The Victor shaft on the Victor claim of the C. O. D. Consolidated is being put in shape for operation on company account, and the management will soon start opening the shoots that were exposed in the early days of the camp.——The Combination Fraction is hauling ore from the mine to the mill of the Nevada Goldfield Reduction Co., and it is understood that the 90-ton plant will be started on Fraction ore June 1.——The Goldfield-Silver Peak, 12 miles north of Blair, has been operated by Meginness Brothers for two months under lease and the results of a recent mill-run were very satisfactory.

LANDER COUNTY

C. P. Nellist and C. T. Linluy, of Kansas City, have purchased the 100-ton mill of the Cortez Metals Recovery Co., at Cortez, for $20,000 and will continue to operate the plant.

NYE COUNTY

(Special Correspondence).—The West End has installed three 50-kw. transformers in the new transformer house and is preparing to operate 10 machine-drills. No. 6 raise 300 ft. west of the shaft has exposed 8 ft. of milling ore. ——The Thanksgiving mine at Manhattan reports the opening of four feet of ore assaying $164 per ton in the west drift on the 425-ft. level.——At the Gold Crater the drifts have opened three feet of $30 ore on the 100-ft. level for a distance of 150 ft.——The Union lessees have leased the Canyon mill and will handle custom ore in addition to their own.——The Eclipse company has commenced treating ore in its cyanide plant.

Tonopah, May 13.

STOREY COUNTY

A raise has been started from the south drift from cross-cut No. 1 on the 2300-ft. level of the Ophir mine in the Virginia City district. At this point the drift cut 40 ft. of ore and it is to determine the extent of this that the raise has been started.——The Consolidated Virginia continues sending low-grade ore to the mill which is stoped on the 1800-ft. level.——Joseph F. Dietrich, who has been operating a lease successfully on the outcrop of the Best & Belcher mine, has secured a sub-lease on the Chollar workings above the 218-ft. level and has put several men at work prospecting the ground.

NEW MEXICO

OTERO COUNTY

Since the middle of February H. Vincent Wallace has been at Bent installing a hydro-electric plant consisting of a Platt-Francis turbine, to drive a Norwalk high-speed air-

Map of New Mexico.

compressor, and a 100-kw. Westinghouse A. C. 3-phase 60-cycle generator at 440 volts for the Talarosa Copper Co. The electric power is to be used to operate the concentrating mill which will have a capacity of 240 tons per day.

OREGON

BAKER COUNTY

It is learned that the Iron Dike mine, at Homestead, which has been under bond to the Lewisohn interests in New York, and on which some development work has been done since last October, has reverted to its owners, the Iron Dike Copper Co. Frank E. Pierce remains in charge as manager.

UTAH

BEAVER COUNTY

The Moscow Mining & Milling Co., operating in the Star district, will pay its first dividend on July 5 when it will

have settled all its debts and have a surplus in the treasury. The ore on the 400-ft. level has been driven on for over 350 ft. and a winze from the level has been sunk 100 ft. in ore.——Two feet of lead-silver ore worth about $30 per ton has been opened in the old Talisman workings of the Cedar-Talisman mine and a car of sorted ore will be shipped early in June.——The Utah United Copper Co., having 12 claims close to Solus station, is developing on what is claimed to be the Horn Silver contact, which is of limestone and monzonite-granite. A 265-ft. shaft has been sunk, in which iron-copper sulphide was found all the way down. At 230 ft. massive iron ore was obtained that assayed 5% copper, and at a depth of 260 ft. the orebody was 17 ft. wide. A. J. McMullen is superintendent.

BOX ELDER COUNTY

The Salt Lake Copper Co.'s mine continues to be a regular shipper of good-grade carbonate copper ore, as it has been for the past three years. Since last October it has been found to be more profitable to work it under a leasing system, which has proved satisfactory both to lessor and lessee. The property is in charge of N. B. Fisher, as manager.

JUAB COUNTY

Work is to be resumed at the Victoria property at Tintic and the shaft sunk to the 1000-ft. level.——The Iron Blossom shaft is now down 1560 ft. A stope has been started on the shoot that was recently opened on the 500-ft. level of the No. 1 shaft, and several cars assaying over 20% lead with a fair amount of silver shipped to the smelter.——The boilers which are to form part of the new equipment at the Chief Consolidated have been shipped from Racine and the new hoist will be forwarded to the mine some time in June. There is a good showing of ore 20 ft. above the 1600-ft. level, and on the 1400 the raise has opened another shoot.

The Iron King, controlled by E. Luce of Provo, is shipping 50 tons per day of oxidized iron ore to the smelting plants. The mine is being further opened by a 2650-ft. tunnel, which is to cut the orebody 200 ft. ahead. Present production is from a 600-ft. shaft, with levels into the ore from the 400 and 600-ft. stations.

SALT LAKE COUNTY

The litigation as to apex rights on a fissure vein, in Bingham, between the Utah Metal Mining Co. and the New England Gold Copper Co. is in a fair way to be settled out of court. An examination of report on the contested orebody was recently made by W. A. Wilson, of Salt Lake. The two properties are on Muddy fork, a branch of Carr fork.——The Columbus Consolidated Mining Co., operating the Columbus mine and mill at Alta, is mining and concentrating 100 tons of ore per day, producing 20 tons of concentrate. The ore averages about 30 oz. silver, 30% lead, 5% copper, and $1 per ton gold.

SUMMIT COUNTY

Free & Taylor, the contractors who are to drive the Snake Creek tunnel 14,000 ft. to develop the Park City ores, have completed the installation of a compressor, and are soon to start work with machine-drills in the tunnel which is now in 30 ft. The electric line from the Snake Creek powerhouse has been completed and supplies for several months' operations are on the ground.——The Utah Mines Coalition Co., having 15 claims at the head of Big Cottonwood canyon, included in which is the Black Bess mine, has driven a 2000-ft. cross-cut within the last 14 months, which is to be extended 300 ft. farther to intersect the Black Bess vein at a depth of 1000 ft. A raise then is to be made to the old shaft through which the property was formerly operated. The equipment includes a gasoline engine and a 5-drill compressor. Duncan McVichie, J. A. Pollock, H. J. Mahon are concerned in the property, of which R. H. Strickland is superintendent.

WASHINGTON

FERRY COUNTY

Twenty thousand dollars at the rate of one cent per share was paid as a dividend by the Pearl Consolidated Mining Co. on May 10 as the proceeds of the lease and bond on the Lone Pine Surprise group in Republic, held by the Republic Mines Corporation. The first dividend of one-half cent per share was wholly obtained from the first cash payment made by the lessees before taking possession of the Pearl company's property. The second of one cent per share was made up equally from a cash payment and from royalties on shipments. The third is wholly due to royalties, which apply as payments on the bond. Of the ore recently shipped, one car was from the high-grade shoot on the Surprise and netted more than $8700. The carload previously from this orebody netted over $10,000. The rest of the ore from the group has varied in value from $18 to $70 per ton.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—The Consolidated Mining & Smelting Co. of Canada has recently secured control of the Molly Gibson mine on Kokanee creek. This property is one of the old time shippers of the district and will be re-opened and worked extensively by the Consolidated company.——A large transaction was effected in Bayonne last week, when C. Manford, of Vancouver, secured a bond on 21 claims in that camp for $225,000, paying $22,500 down. There is a large quantity of gold ore in sight on the property and a 10-stamp mill will be installed at once. The Bayonne camp is not far from the Sheep Creek district and bids fair to rival it as a gold producer.——Vancouver capitalists have also acquired a group of properties on Deer creek and will begin development work at once. ——The Inland Empire Mining Co. is considering the installation of a stamp-mill on its property near Paulson. ——The Columbia Coal & Coke Co. has begun diamond-drill work on the property on Granite creek.

Rossland, May 14.

ONTARIO

From the 88-ft. level of the Lawson mine at Cobalt the drift has been following the Keewatin vein and has recently opened a 3-in. shoot of 2800-oz. silver ore. The Princess property of the Consolidated company at the head of Cobalt lake is stoping ore on three veins.——The Crown Reserve Mining Co. is having 100 tons of the dump ore treated in the Cobalt Central mill, and if the results prove as satisfactory as anticipated the Crown Reserve will probably erect a concentrator.——The Rochester Cobalt now has three veins, the last one cut being 8 or 10 in. wide and containing a high percentage of native and ruby silver in a calcite gangue.——Some high-grade ore is being taken out of the drifts on the 70-ft. level of the Bellellen property in South Lorrain. This is the old Newman group upon which the most spectacular surface showings in South Lorrain with the exception of the Wettlaufer were made last fall. The shaft was sunk on a lean streak in the vein and it is only recently that the drift tapped the rich shoot.

MEXICO

MEXICO

A new orebody has been opened recently in the Alacrán mine in the Zácualpan district. The company has denounced the water-rights of the Alacrán barranca and will install a hydro-electric plant.——The Chontalpan mine has been taken under new management and will be equipped with modern machinery.——The Reforma Mining Co. has installed a producer-gas plant to furnish power for an electric generator, compressor, and drills. The company is driving a large cross-cut adit to tap the vein.——The Concepción Mining Co. is installing a producer-gas plant.

SONORA

The shaft of the Calumet & Sonora Mining Co., operating two miles north of Sonora cut a body of lead-zinc ore at a depth of 400 ft. An addition has been built at the mill, a Diester slime-table installed, and in the power plant a new 250-hp. boiler has been added to those now in operation. ——The April production of the Greene-Cananea Copper was about the same as the March, which was approximately 3,700,000 lb. It is stated that the company is in a position to produce 6,000,000 lb. of copper per month if the market should warrant it.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

TRESPASS ON MINING CLAIMS—TIME FOR BRINGING ACTION

Under a statute providing that actions for trespass on mining claims and mines must be brought within three years from the time the action accrues, but providing that when a trespass is committed by underground workings on any mining claim, the cause of action shall not accrue until the discovery of the trespass, it was decided by the Supreme Court of Utah that an action for trespass brought eight years after the ore was removed from the mine was not barred by the statute where it was shown that the plaintiff did not have actual knowledge of the trespass prior to six months before the bringing of his action and that accordingly the action was not barred.

Bullion-Beck & Champion Min. Co. *v.* Eureka Hill Min. Co., (Utah) 103 Pac. 881, Aug. '09.

HISTORICAL SKETCH OF NEVADA MINING CLAIMS

A very interesting historical sketch of the origin of the rules of mining and of such early mining claims in Nevada as the Comstock and Canyon claims has recently been given by the Supreme Court of Nevada. The Court suggested that it could properly take judicial notice of the fact that the particular property in controversy was in the region of the earliest discoveries of gold in that State, the region whose history is part and parcel of the history of the Comstock Lode, which in turn was a part of the history of the Government, of such importance as to merit recordation, as long as the nation, which the Comstock helped so effectually to maintain, should last. To this region, from 1859 and until after the seventies the miners from the 'diggins' of California, adventurous spirits from all pars of the nation and the world, gathered, and a large portion of the country was located in accordance with the customs and rules of the miners before the passage of any laws regulating such locations. The court pays tribute to that distinguished lawyer, statesman, and citizen, Hon. William M. Stewart, under whose leadership was enacted by Congress in 1866 the first legislation upon the subject. The distinguished Senator, advocating the passage of the Act, spoke in high praise of the regulations and customs of miners and portrayed in glowing language the wonderful results that had followed the system of free mining, which had prevailed with the tacit consent of the Government. He stated that the legislature of California had wisely declared that the rules and regulations of miners should be received in evidence in all controversies respecting mining claims, and when not in conflict with the constitution or laws of the State or the United States, should govern their determination, and that a series of wise judicial decisions had molded these regulations and customs into "a comprehensive system of common law, embracing not only mining law, broadly speaking, but also regulating the use of water for mining purposes." He declared that the miner's law was a part of the miner's nature; that he had made it and he trusted it and obeyed it; that he had given the honest toil of his life to discover wealth which when found was protected by no higher law than that enacted by himself under the implied sanction of a just and generous Government. He also stated that the proposed Act continued the system of free mining, holding the mineral lands opened to exploration and occupation subject to legislation by Congress and local rules; that it merely recognized the obligation of the Government to respect private rights which had grown up under its tacit consent and approval, and that it proposed no new system, but sanctioned, regulated, and confirmed a system already established, to which the people were attached. The court said that while these statements of the author of the Act in securing its adoption could not control its construction, yet they did show the condition of mining property on the public lands, and its tenure in the absence of legislation, and thus indicated the probable intention of Congress.

Golden *v.* Murphy, (Nev.) 103 Pac. 394, July '09.

COMPANY REPORTS

ALASKA UNITED GOLD MINING COMPANY.

It is charming to witness absolute frankness in a mining report. The Alaska United is a model of what such a report should be. Nothing is hidden; the whole round of operations is revealed by statistics, which are analyzed to interpret their meaning. The balance sheet shows a total income for the year 1909 of $1,090,287, of which $261,743 was profit. Out of this the sum of $234,260 was disbursed in dividends. The year ended with proved ore reserves of 821,821 tons in the Ready Bullion mine, and 296,403 in the 700-Ft. Mine; while there remained in the stopes of these mines, respectively, broken ore to the amount of 294,829 and 239,666 tons. The average assay-value of these reserves was respectively $2.68 and $2.36. The estimate of ore reserves, however, is much higher than the figures above given. This brings the total in the Ready Bullion mine to 1,116,650, and in the 700-Ft. to 536,069 tons; this estimate including ore that must remain in the mine as pillars. The report is teeming with valuable data, from which only a few selections of larger interest are possible. The duty of the machine drills employed is stated to have averaged 40.67 tons broken per drill per shift, the average length of hole drilled being 34.65 ft., labor costs averaging $8.38, explosives $2.08, and supplies, power, and repairs $5.65. In shaft sinking the average depth of hole drilled was 45.08 ft., and tons broken 15.24. The mill of 120 stamps crushed during the year 227,710 tons of ore at a total cost of $56,859 or 24.97c. per ton. The ore yielded in free gold, including copper and base bars, $278,868, or $1.2247 per ton, and $215,359 from concentrate treated, or 94.57 cents per ton, making a total yield of $494,227, or $2.1704 per ton. The running time of the full mill for the year was 351 days, 19 hours, during which time steam was used for power 241 days, 18 hours, and water power 110 days, 1 hour. During the year 1 lb. of chrome steel in the shoes crushed 2.63 tons of ore, and 1 lb. of iron in the dies, cast locally, crushed 5 tons, at a total cost for the iron and steel consumed of 2.62c. per ton of ore. The stamp-duty was 5.37 tons per diem. The supplies for the mill show the following totals, which constitute renewals: shoes 510, dies 310, cams 15, cam shafts 14, stems broken and replaced 595, new stems 23, tappets 48, boss-heads 6, vanner belts 7. The analysis of quicksilver used and consumed is most interesting. The quantity fed, in ounces, and the places of application, were as follows: batteries 38,123, plates 1895, vanners 658, elsewhere 7822, total 48,498. The quicksilver recovered from retorting was 32,919, and the total loss is estimated at 15,807, or 32.59%, the distribution of losses being, in retorting 242 oz., and in the mill 15,565. These details apply to the Ready Bullion mill, which is representative of the work done in the 700-Ft. mill of 100 stamps, where, for example, the quicksilver loss was 32.71%, the stamp-duty 5.41 tons, and the total cost for iron and steel consumed in shoes and dies per ton of ore crushed was 2.5c. The latter mill crushed 184,799 tons at a total cost of $45,615, or 24.68c. per ton. The ore yielded in free gold, including base bars, $265,607, or $1.4373 per ton, and $224,083 from concentrate treated, or $1.2127 per ton, making a total yield of $489,690, or $2.65 per ton. Drill-duty in the 700-Ft. mine works out at an average for all classes of service of 26.68 tons of rock broken, and 26.89 ft. of hole drilled per shift. The elements of these figures are worth re-stating, the duty having been, for stoping 36.98 tons broken with 24.99 ft. of hole drilled; development, 7.89 tons and 31.88 ft. respectively; and cutting out 12.72 tons and 27.06 ft. The average number of tons of ore broken per foot of hole drilled during the year was 0.99. In the Ready Bullion mine the average per foot of hole drilled was 1.17 tons of ore and waste broken. From the Ready Bullion mill the total concentrate-yield was 4390 tons, and from the 700-Ft. 3230. In the two cases the recovery by Amalgamation was $1.2247 and $1.4373 and from concentrate 94.57c. and $1.2127 respectively. The operating costs of the Ready Bullion were $1.63 per ton, and of the 700-Ft. $1.74. The number of employees was 489, and the accidents 4, making an average rate of 2.04 per thousand.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. H. Ball is at Naica, Chihuahua.

H. W. Hardinge will be in Denver soon.

J. E. Spurr, was in Los Angeles recently.

L. J. Mayreis is examining mines in Bolivia.

M. K. Shaler has left New York for the Congo.

Robert M. Raymond has been in San Francisco.

F. S. Wayne, of New York, is in San Francisco.

W. G. Miller has gone to the Porcupine district.

Fritz Wolf has gone to Seven Troughs, Nevada.

George H. Garrey was in San Francisco this week.

Max F. Abbe, of Abbé Engineering Co., sailed for Europe May 10. He will be absent six months.

W. D.Smith, chief of the Division of Mines, Manila, P. I., visited the Bulacan iron fields recently.

C. L. Herrick, of Denver, has been in San Francisco lately.

Guy A. R. Lewington has arrived at Dawson, Yukon Territory.

Juan Felix Brandes has left London for a trip to France and Germany.

D'Arcy Weatherbe will go to Siberia this year with C. W. Purington.

Thomas J. Clinton has returned to Detroit from a visit to San Francisco.

A. W. Geiger has sold his interests at Cortez, Nevada, and is in San Francisco.

George W. Heintz, manager of the United States S. R. & M. Co., was in San Francisco.

T. G. Janney, manager of the Shasta Dredging Co., has returned to Redding, California.

George W. Metcalfe, manager of the Mammoth Copper Mining Co., was in San Francisco.

A. A. Blow will deliver the commencement address at the Colorado School of Mines, May 27.

J. B. Tyrrell has been elected president of the Canadian Institute, the oldest scientific society in Canada.

Leo. Von Rosenberg, of New York, has returned from Peru and gone to Georgia to examine gold properties.

J. H. Young has become manager of the Guggenheim interests in the Northwest, with headquarters at Seattle, Washington.

Gardner F. Williams and W. P. Blake were given the degree of LL.D. at the Semi-Centennial of the University of California, May 25.

Errol Mac Boyle has returned from the Seven Troughs district of Nevada. He will sail on the steamer *Mongolia* Tuesday for the Philippine Islands.

Morril B. Spaulding met with a serious accident April 25 while engaged in progessional work in South Carolina. Both of his legs were broken, but fortunately, no other complications have arisen, and his speedy recovery appears now to be assured.

Underground traveling in London increases at an astonishing rate. The number of passengers carried for the first half of the present year by the Metropolitan Underground railway was 16,503,395, against 5,823,437 in 1863 and 7,462,283 in 1867.—July 13, 1867.

The Erie Railway Co. in New York, it is stated, are about doing away with the use of wood on their locomotives, and have already commenced selling off the wood they have on hand. Coal is to be used hereafter.—July 6, 1867.

The Union Pacific railroad is now opened to Julesburg, 376 miles west of Omaha, and daily trains have commenced running each way. Over 500,000 pounds of freight was awaiting the opening.—August 17, 1867.

Personal

What some engineers were doing long ago.

Louis Janin is in Grass Valley.—March 30, 1895.

A. T. Dewey starts for the East by steamer Monday.—August 17, 1867.

A. A. Blow, of South Africa, is on his way to London.—March 25, 1899.

Ross E. Browne expects to return from London about March 7.—January 28, 1899.

Leo Von Rosenberg has returned to San Francisco from Arizona and gone to New York.—May 6, 1899.

Prof. Chables H. Hitchcock has been appointed State Geologist of New Hampshire.—November 14, 1868.

Ben Stanley Revett is in San Francisco en route to Colorado to examine mining property.—November 13, 1897.

Alfred James of Glasgow, Scotland, representing. the Cassel Gold Extracting Co., is visiting this State.—July 21, 1894.

Prof. Geo. Davidson has assumed the superintendence of the Pacific division of the Coast Survey.—December 26, 1868.

R. W. Raymond, Esq., Mining Commissioner of the Pacific States, left this city on Thursday last for the interior.—June 13, 1868.

T. A. Rickard, State Geologist of Colorado, is visiting San Francisco with his bride on their wedding trip.—January 7, 1899.

Baron von Richthofen will accompany J. Ross Browne and C. D. Poston on the Chinese mission, in the character of geologist.—August 1, 1868.

Thos. H. Leggett, president and general manager of the Standard Cons. Mine at Bodie, is in the city on a brief business trip.—October 27, 1894.

H. W. Turner of the U. S. Geological Survey is in Butte county securing material for a map of the Sierras in that part of the State.—July 21, 1894.

Guido Kustel has transferred his assaying and metallurgical business at 611 Commercial street to Lopold Kuh of Virginia City.—November 28, 1868.

J. Ross Browne, our new minister to China and late Commissioner of Mining Statistics, arrived in this city on Friday last from New York.—July 11, 1868.

Gardner F. Williams and J. E. Davis have recently returned home from several years' stay at the Mining Academy at Freiberg, Saxony.—November 14, 1868.

W. C. Ralston, the secretary of the California Miners' Association, returned this week from a six months' sojourn in London and Paris.—May 18, 1895.

George W. Starr has resigned the superintendency of the original Empire Mining Co. of Grass Valley to go to South Africa. Robert Walker is his successor.—July 29, 1893.

Prof. R. Pumpelly, the well known geologist and mineralogist, has been engaged the past summer in exploring the Menominee region near Lake Superior.—October 26, 1867.

John Hays Hammond has recently returned from a business trip to London. He is about to leave California for some months and will go to South Africa on professional business.—June 17, 1893.

Baron von Koschkill, a geologist and mining engineer of Tiflis, Russia, is visiting the principal mining districts of the United States under orders from the Russian Government.—November 7, 1868.

A. de Vial and Alexis Janin, recently students at Freiberg, Saxony, arrived here a few days ago. The former leaves today for Guaymas, Sonora; the latter goes to Virginia City.—November 28, 1868.

D. N. Coffin has resigned from the superintendency of the W. Y. O. D. mine at Grass Valley. His successor is W. H. Shockley, who was superintendent of the Mount Diablo mine at Candelaria, Nevada, now closed owing to the decline in silver.—July 29, 1893.

Markets

Quotations of Former Years

STOCK MARKET

Ophir.—Sanborn's circular of last week quotes sales of 468 shares of Ophir Stock at rates from $2400 to $2750 per foot. The sales at the Board for the week have been very uniform—from $2450 to $2475 having dropped somewhat from last week.

Gould & Curry.—Fifty shares were sold last week for $2550 and 40 for $2560, 1st January. The shares at the Board for the present week are quoted at from $2475 to $2500.

Central.—Thirty-six shares were sold at $1425 and the same number subsequently for $1600 as per Sanborn's circular.

California after remaining quiet for several weeks is quoted at $1200, an advance of $100. Two hundred and forty shares sold for $1250, 1st of March.

Chollar is rapidly advancing and is quoted on the Stock Board from $305 to $350. $500 was asked Wednesday.

Potosi has been but little enquired for. Small transactions are quoted at from $75 to $85.

North Potosi is quoted at $7 offered $6.50 asked.

Sierra Nevada is quoted at to $65. Forty shares changed hands at that figure last week.

Burning Moscow is quoted at from $63 to $65.

December 13, 1862.

The Mining Share Market still continues its unusual activity. The amount of transactions the past week foot up to the very large aggregate of $1,972,807—a considerable excess over last week.

Ophir shares opened the week with a decline of $50 which was steadily maintained until Thursday when they suddenly dropped to $1550 and remained unactive on Friday. 594 shares have changed hands since our last issue.

Chollar shares continue to be largely dealt in, and at declining rates. We quote sales of 582 shares at from $285 to $352 cash. We notice a single transaction on Saturday of 64 shares at $1000, buyer 60 days. Much mystery appears to hang around the operations of this company. They are still sinking on their mine.

Melones has still further advanced. It reached $75 on Saturday last, at which rate 40 feet found purchasers. On Monday it receded to $55; recovered to $75 on Tuesday and closed yesterday at $62½. We learn of a report of a rich strike, to which we gave credence last week, was without foundation. The present advance is the result of an improved management at the mine.

January 30, 1864.

PUBLICATIONS RECEIVED

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

HISTORY OF THE SAN FRANCISCO STOCK AND EXCHANGE BOARD. By Jos. L. King. Pp. 373, ill. Published by the author. San Francisco, 1910. Price $2.

Literature is a by-product of mining as it is of other industries, and to mining men, if not, indeed, to others. The books which tell of mining and its related industries are more interesting than the most popular 'best seller'. When the author has at hand such a mass of incident and biography as Mr. King was able to command, coupled with an 'experiencing nature', and the fortunate ability to say 'all of this I saw and much of it I was', the reader may well anticipate a treat. And he will not be disappointed. From the fragments of the records of the Board saved from the fire, from the files of the MINING AND SCIENTIFIC PRESS and the daily papers, from old letters, personal recollection, and reminiscences of friends, the chairman of the Board has built a fascinating story. The organization of the Board, its early history, the Hale & Norcross corner, the Ophir contest, the great market of bonanza days, the suspension of the Bank of California—all these and many other topics are treated on the basis of first-hand information. Anecdotes of James R. Keene, B. F. Sherwood, Mark L. McDonald, William Sharon, D. O. Mills, the 'Bonanza firm of Flood, Mackay, Fair, and O'Brien, and give graphic pictures of men and times. As a recent searcher for data regarding these men and their lives, the reviewer can testify that Mr. King's book supplies much not otherwise available. The chapter on broker's superstitions is exceedingly readable. For example: "Should a black cat whine at your front door, take the cat in right away, and if it purrs and rubs against your leg, let us know what you buy that day and we will all follow you." Or: "When you meet a cross-eyed man, looking hard at you, and you are certain it is you he is staring at, you must instantly go out of the Board and do nothing that day." We may cherish a lingering doubt whether implicitly following these rules will bring wealth, but they at least bring a laugh and that makes for health.

PRACTICE AND THEORY OF THE INJECTOR. By Strickland L. Kneass. Pp. 175, ill., index. John Wiley & Sons, New York, 1910. Price $1.50.

This is the third edition of a standard work covering fully the history, development, construction, and use of injectors. It includes also a study of the requirements of modern railroad practice, methods of feeding locomotive boilers, feed-water heating, efficient feeding, use of scale-bearing water, and similar topics of vital interest to engineers. It is well printed and bound, and is authoritative.

TESTS OF WASHED GRADES OF ILLINOIS COAL. By C. S. McGovney. Univ. Illinois, Eng. Exper. Station, Bull. 39. Pp. 146. Urbana, 1909.

An illuminating discussion of the steaming qualities of washed coal.

GOLD, SILVER, COPPER, LEAD, and ZINC IN 1908. By Waldemar Lindgren, H. D. McCaskey, B. S. Butler, C. E. Siebenthal, and others. U. S. Geol. Surv. Extract from Min. Res. 1908. Pp. 157-681. Washington, 1910.

A convenient handbook of production.

PURCHASE OF COAL BY THE GOVERNMENT UNDER SPECIFICATIONS. By George S. Pope. U. S. Geol. Surv., Bull. 428. Pp. 80. Washington, 1910.

An account, with analyses, of the actual operation of the system.

INNOKO GOLD-PLACER DISTRICT, ALASKA. By A. G. Maddren, U. S. Geol. Surv., Bull. 410. Pp. 86, ill., index, maps. Washington, 1910.

A useful summary of existing cartographic and geologic data regarding a district attracting much attention.

PROGRESS OF THE MINERAL INDUSTRY OF TASMANIA. By W. H. Wallace. Pp. 21. Tasmania, 1910.

The customary quarterly review, in this case covering the period ended December 31, 1909. A slight increase, mainly in silver and copper, is shown by comparison with the figures of the preceding quarter.

An Ancient Wire Rope

Until very recently it was supposed that wire rope was an invention of the nineteenth century; but in 1895 there was dug up at Pompeii a wire rope that had been buried for more than 1800 years. The illustration herewith is

from a photograph of this rope secured by the Broderick & Bascom Rope Co. at the Musio Borbonico in Naples, where this interesting relic is kept. The rope is about 15 ft. long and ½ in. diam., laid in three strands of 15 wires each. The exact use of this rope is not known, but it is thought from its surroundings to have been used as a sort of crane. Now, if this rope was used and worn out nearly twenty centuries ago, is it improbable that the Egyptians used similar ropes even earlier? We know the Egyptians made hemp ropes. That the art of rope making from fibre was known in Old Testament times is evinced by the aphorism in Ecclesiastes 4:lv, "A three-fold cord (rope) is not quickly broken." We know the Egyptians used wire in many ways. They were the wisest and most practical of all ancient peoples. They dug a canal where the Suez canal now is. Their ships circumnavigated Africa and traded in India before Greece or Rome had even emerged from barbarism. A recent discovery has brought to light an iron tool peculiarly preserved among some annealed copper implements. It does not exceed probability to assume that such a wonderful people, who knew the uses of wire, of fibre ropes, and of iron, may have made and employed wire ropes.

Dividends.

Dividend No. 31 of 20c. per share has been declared by the Alaska United G. M. Co., payable May 28, 1910.

Dividend No. 59 of 30c. per share has been declared by the Alaska Mexican G. M. Co., payable May 28, 1910.

Dividend No. 89 of 50c. per share has been declared by the Alaska Treadwell G. M. Co., payable May 28, 1910.

On Thursday, May 5, 1910, the Bunker Hill & Sullivan M. & C. Co. paid Dividend No. 152 of $98,100. This makes the amount of dividends paid since January 1, 1910, $353,100, and the total to date $11,639,100.

In San Francisco greenbacks are worth 2½c. more per dollar than in New York.—January 16, 1864.

Electric Locomotives on Exceptionally Heavy Grades

Satisfactory operation of electrical apparatus under severe conditions is illustrated by the installation at Holt & Gregg's lime quarry at Kennett, Shasta county, California. This quarry is situated near the large copper mines and smelter of the United States S. R. & M. Co., and supplies the limestone which is used as a flux in smelting the ore. It is about two miles from where the rock is stored for the smelting company and about 2000 ft. above the bins. In order to transport it to this point it was necessary to build a road with many curves and heavy grades. There is a total of 35 curves with a minimum radius of 35 ft. and a maximum of 33. The entire road is laid on heavy grades varying from 4 to 12%, the average being about 7. This grade was originally laid out for a wagon-road, but was afterward used for a 30-in. mule tramway, equipped with 30-lh. T-rails laid on 4 by 6-in. ties 5 ft. long. The track is well ballasted with limestone and the cars are small so as to be handled by the mules. The demand for rock became so great that it was not possible to supply it with this equipment, and an electric mining locomotive was purchased. The cars are now operated in trains of three,

Climbing 12 Per Cent Grades.

each car weighing 4400 lb. empty and consisting of a wooden body mounted on substantial double trucks, having a wheelbase of 3 ft. A complete brake equipment has been provided, including both track and wheel brakes. The mining locomotive has a rating of 11 tons and is equipped with two 42-hp. 550-volt motors. Because of the heavy grades and consequent wear of the wheels by the brakes, the locomotives were equipped with track brakes in addition to the standard wheel brakes. This track brake consists of a steel shoe or slipper, mounted under each side frame at the middle point of the wheel base. This shoe can be applied to the rails with heavy pressure by means of a screw and nut mechanism placed at the operating end of the locomotive. As the locomotives have to be retarded throughout the down-grade trip, the wear on the wheel tread would be excessive unless track brakes were used. By their use the wear is confined to a simple and readily renewable casting. It was planned that the time for hauling this train from the ore-bins to the quarry should be 15 to 18 minutes with intervals between of about 10 minutes. The cars are then loaded and started down the grade by gravity, followed by a locomotive which picks them up after they have been unloaded at the ore-bins. These locomotives have run steadily all day, making a total of about twelve trips. Afterward the business increased so rapidly that two more locomotives were purchased.

Owing to the mountainous country, it was necessary to install the power station at the end of the line. The equipment at present consists of a 60-kw. and 150-kw. motor generator set, both compounded for 550/575 volts, the two being operated in parallel. Owing to the long haul over this road, the motor generator sets are operating under a heavy continuous overload, and from tests recently made it was found that this overload was about 25%. Up to the present time they have apparently suffered no injury from this severe service. The complete equipment was furnished by the General Electric Co., of Schenectady, New York.

COMMERCIAL PARAGRAPHS

The Hardinge Conical Mill Co., New York, advises that the Miami Copper Co. has ordered four Hardinge mills for use at Globe, Arizona.

Wallace & Summerhayes have closed their offices at Nogales, Arizona, and established themselves in the Trust building at El Paso, Texas.

The Ingersoll-Rand Co. announces the removal of its Chicago office from the Old Colony building to the Peoples' Gas building, 150 Michigan avenue.

The Kino Metallurgical Laboratories and Smith, Emery & Co., of San Francisco, have been consolidated and the business of the two firms will be conducted from the office of the latter.

Free & Taylor, of Salt Lake, who have taken the contract to drive the 14,000-ft. tunnel for the Snake Creek M. & T. Co., in Park City district, Utah, have commenced work with two drills, working three shifts.

The students of the A. Van Der Naillen School of Engineering, Oakland, California, recently spent some time in Napa and Lake counties on the annual summer excursion. The purpose of the trip is to give the boys a chance to do practical work in the different engineering courses.

The Broderick & Bascom Rope Co., St. Louis, is distributing a desk paper-knife made from its Yellow Strand wire rope. The individual wires from which the cable is made have a tensile strength of between 240,000 and 260,000 lb. per square inch. It is to be hoped that the knife will be helpful in 'loosening' many orders for the makers of Yellow Strand wire rope.

A light railway possessing many interesting and unusual features was built some time ago by the Orenstein-Arthur Koppel Co., for the Otavi Mines & Railway Co. in German Southwest Africa. It is the longest narrow-gauge (2-ft.) railway in the world, being 361 miles in length. The rails weigh 30 lb. per yard. Steel ties are used, the maximum gradient is 1 in 50, and the sharpest curve has a radius of 260 ft. The line was built during the 'Herrero' war in less than three years. This and many other interesting installations are described and illustrated in Album No. 742 issued by the Orenstein-Arthur Koppel Company.

The Revere Rubber Co. is devoting special attention to the mining business at its new Pacific Coast branch, 543 Market street, San Francisco. A complete stock of special goods, such as concentrator belts, air and steam drill hose, suction hose, is always on hand. Four grades of transmission belt are carried in sizes up to 24 in. The new 'Paramo' conveyor belt, with a convex shaped cover, is meeting with great success. The belt is flexible and the construction of the cover causes the belt to trough naturally. The 'Revero' and 'Silvertown' elevator belts for bucket elevators are worthy of special mention. This company has always made it a point to study mining conditions and construct its goods accordingly. This is probably evidenced most fully by the favorable reports received from its gold dredge stacking belts. Descriptive circulars on any goods will be sent cheerfully from the San Francisco branch.

CATALOGUES RECEIVED

The Hunt Filter Co., Mills Building, San Francisco. 'Hunt Continuous Filter'. Revised catalogue. Illustrated. 6 by 9 inches. 8 pages.

Lehigh Car, Wheel & Axle Works, Catasauqua, Pennsylvania. 'Fuller Face-Hardened Sprocket Wheels'. Illustrated. 20 pages. 6 by 9 inches.

Hydraulic Supply Mfg. Co, Seattle, Washington. Catalogue of riveted steel pipe and hydraulic mining machinery. Illustrated. 32 pages. 6 by 9 inches.

Hardinge Conical Mill Co., 43 Wall street, New York. Catalogue No. 7, 'Hardinge Patent Conical Ball and Pebble Mills. Illustrated. 20 pages. 6 by 9 inches.

EDITORIAL.

FAIRBANKS, Alaska, may be far away from the United States, measured in miles, but by trail and telegraph its citizens keep in close touch. The special issue of the *Fairbanks Times* published April 3 is quite metropolitan in appearance, and in content is far more interesting than most Sunday supplements published in the States.

STILL the oil war wages in Mexico. Mr. H. Clay Pierce is on the ground, and presumably he is ready to listen to the voice of conciliation. So are S. Pearson & Son, according to those who profess to know; nevertheless Sir Weetman Pearson has gone off to the Argentine with a cool indifference to results in Mexico that must have its effect, even if the Englishman is bluffing. Meanwhile, we believe, each concern is pleased to have the public buy its oil from the other fellow—at present cut-rates.

CORNWALL has been a great training ground for miners, and in every mining district of any size a few Cornishmen are sure to be found. It still has important mines and is still a proving ground for new devices. Mr. Thomas Rickard, who writes in this issue on 'Fifty Years in Cornwall', has not only the advantage of intimate personal experience with that Duchy, extending back through the years, but has also seen at first-hand the introduction of Cornish methods and development of independent systems throughout the world. His article arrived too late for use in our anniversary number last week. The younger men who have known Mr. T. A. Rickard will probably think of Mr. Thomas Rickard as his father, but we sacrifice no modesty, because of our intimate relations with both father and son, in saying that they shed lustre each upon the other.

ONYX-MARBLE has been difficult to account for: its origin has been obscure, and it has not been observed in process of formation. Mr. E. M. Lawton contributes a brief paper to this issue, throwing out a valuable suggestion of genesis by metamorphism. This seems reasonable; in fact another such occurrence, in a small way, is to be seen on the north side of Silver lake in San Bernardino county, California. It is doubtful whether metamorphism, however, will account for all deposits of this material. The onyx-marbles of the world have been particularly studied by Mr. George P. Merrill and Mr. Courtenay De Kalb, both of whom have published monographs on the subject. While not in agreement on some points, they both claim deposition from hot solutions as a necessary condition. Cave-marbles are usually calcite; onyx-marble is aragonite. It would be interesting to determine the mineral in the case referred to in Oaxaca.

Anaconda Copper Company

Criticism from a stock-market point of view has been directed against the Anaconda Copper Mining Company on account of the showing made for the year 1909. A price of $40 per share does indeed seem unwarranted when it is considered that the earnings per share were $1.78. The company is not to blame for what the public chooses to pay for stock, but without prospects for immediate betterment of general trade conditions it is, to say the least, a doubtful policy to continue using up an accumulated surplus in the payment of unearned dividends. During 1909 the Anaconda disbursed $2,400,000 to shareholders, this being $265,227 more than the available profits. The surplus now stands at $4,679,216, having been gradually eroded from the stately height of $6,261,460 in 1907, by persistence in this policy. We believe that it is better practice to face the facts, to live within one's income, and to keep a surplus well guarded during days of stress. However, if the speculative public chooses to pay $40 for a stock of $25 par value under such circumstances it is no affair of ours. On the other hand, it is a matter of deep concern to everyone interested in mining that a great enterprise like Anaconda should be maintained upon a secure footing. In some ways it is the premier copper mine of the world; it has superb prospects for the future; its plant is unexcelled; the milling and metallurgical operations are conducted in a masterly manner, under the direction of Mr. E. P. Mathewson; but there are difficulties still to be overcome, and the company may find need for its resources before improvement in the price of copper shall increase its earning power. The smoke-problem is still before the courts, and the economical way out is not apparent. While the expenses are not analyzed in this report, the mining costs are known to be high. The most encouraging feature of the year was the increase in metal recovered from 57.6 pounds per ton in 1908 to 59.7; the improvement, moreover, was not spasmodic, as shown by the fact that the product in 1907 was 56.1 pounds per ton, which in turn was on approximately the same level as in 1906. The total output for 1909 was 75,860,194 pounds of copper from 1,282,681 tons of ore, and the recovery of precious metals was 2,363,184 ounces of silver and 7466 of gold. The total of ore from all sources treated in the Anaconda reduction works was 3,517,386 tons. The gross costs were $9,820,897, and the cost per ton of ore was $7.65. The net cost of the copper produced, after crediting gold and silver, was 10.7 cents per pound, the precious metal credit being 0.4 cent per pound. During 1909 the company suffered embarrassments from blockades on the railroads cutting off the supply of coke, and also from a mine-fire which put the Anaconda shaft out of commission for many months. This necessitated hoisting the ore from the Anaconda workings through the Never Sweat and St. Lawrence shafts. Among the outside operations of the company are coal mining and lumbering, the sales of coal from the mines at Belt, Montana, being 108,600 tons out of a total production of 147,263 for the year, and the lumber sales reached 22,802,883 feet out of a gross cut of over 24 million. The possibilities of producing acid phosphate from the smelter-fume have been extensively studied, without encouraging prospects of earning a profit. The demand for fertilizers in the West is not yet sufficient to consume a large quantity, and the long haul to the East places a prohibitive freight-charge against the product. Mr. B. B. Thayer, president of the company, calls attention to the difficulty of applying apex rights to determine ownership of orebodies in Butte. He states that the only solution of these conflicts lies in a consolidation of the Butte mines. The relations of the deposits are such that economical mining cannot be conducted in many places upon adjacent properties by independent operation, so that vertical side-line agreements do not avail to remove friction and difficulty. We heartily endorse his position in this matter. In conclusion, it is important to observe that the stock of copper, silver, and gold on hand at the end of 1909 was 5,986,964 pounds, as compared with 6,169,245 for 1908, and that the receipts from sales of these metals during the year were $11,591,845, while in 1908 the corresponding figure was $9,060,472. Considering the increased output for last year this is an encouraging result.

William Phipps Blake

Death has just called the oldest practising mining engineer in America. William Phipps Blake has been actively identified with mining ever since the days of the California gold excitement. He came into the field at a time when men prepared by scientific education were rare in this country. On that account he found prompt demand for his services, and he was known in every mining district of the West. He was a man of deep penetration and of alert intellect, and he soon made his power recognized, so that his aid and advice in scientific matters were sought by the Government as well as by individuals and corporations. He was summoned to Japan in 1862 to conduct scientific investigations for the Imperial Government. On his return he explored the Stickeen river, in Alaska, rendering a report to Mr. Seward, the Secretary of State, which confirmed the reports of mineral wealth and materially aided in securing legislative consent to the purchase of that territory from Russia. It is remarkable that Mr. Blake, at that early time, should have foreseen the probabilities of important resources of gold in Alaska. We were fortunate in publishing an account of this reconnaissance in our golden jubilee issue last week. It was the last article ever written by Mr. Blake, as it was also the first explanation given to the public of the circumstances under which his Alaskan report was prepared. In 1864 he was professor of mineralogy and geology in the College of California. He became geologist to the Commission despatched by President Grant to Santo Domingo in 1871, when the United States was contemplating the annexation of that country. As commissioner to international expositions his career has been notable. He was executive commissioner to the Centennial Exposition in 1876, and in 1878 he was appointed as one of the representatives from the United States at the Paris Exposition. He reported

this world's fair for the MINING AND SCIENTIFIC PRESS, writing a series of articles on metallurgic and mining progress as there revealed, which had great influence in forwarding the development of those arts in this country. In 1894 he assumed the post of director of the School of Mines of the University of Arizona, becoming professor emeritus in 1905; at the same time he served Arizona in the capacity of territorial geologist.

His published reports and articles number several hundred titles, a partial list of which was recently printed by Mr. Kendric Charles Babcock, president of the University of Arizona. The 'Geological Reconnaissance of California', a work which is now of great historic value, he prepared in 1855; other well known volumes from his pen are 'Silver Ores and Silver Mines', 'Tombstone and Its Mines', and 'Ceramic Art and Glass'. For a brief period in the latter fifties he was editor of the *Mining Magazine*, a paper then published in New York.

Mr. Blake was born in 1826 in New York. He prided himself upon his descent from William Blake of Dorchester, Massachusetts, who arrived in the New World in 1630. Another distinction was that of belonging to the first class which graduated from the Yale Scientific School. Within three weeks of his death he made an examination of a gold mine near the Colorado river in Arizona. Thence he came to Berkeley to receive what proved to be the last honor of his long and useful life, the honorary degree of LL.D., conferred upon him by the University of California on May 18. His name is interwoven with the history of the development of American mining.

The Quicksilver Situation

Quicksilver has been unsteady in price for a considerable period, but as a matter of fact it has not varied in price as widely as other metals, nor as sharply as would be expected from the decreased demand. A remarkable complication of factors enter into the quicksilver situation. There has been an increase in the cost of labor over past years; the deposits themselves have either been largely exhausted or the grade of metal in the ore has lessened. In the early days ore as rich as 20 per cent in mercury was regularly treated; 3 and 4 per cent ore was common; the depths to which mining was carried had not become great. At the same time the metallurgic processes were crude and the losses were large. Today an ore yielding three-quarters of one per cent of mercury is moderately high grade, and at least one of the large California producers is treating material that will not average 0.5 per cent. Formerly the demand was fairly steady. The hydraulic miners consumed great quantities, and in their case consumption was literal, absolute, irrevocable. The wastage into the tailing piles was huge. There will be those who will deny this charge, but our remarks are founded upon personal observation. The waste in stamp-milling was also a great factor. Few companies report their quicksilver loss, but it probably exceeds 20 per cent; the United Alaska Gold Mining Company recently confessed to a total quicksilver loss of 32 per cent, of which the greater part was naturally in milling, not in retorting. In the pan-amalgamation process the wastage was enormous; great quantities of quicksilver were lost by 'flouring'. The amount permanently locked up in the normal operation of a plant was also immense. The patio process made a heavy draft upon the quicksilver resources of the world; here the losses were both mechanical and chemical. From 1875 to 1883, when silver mining was at its zenith, the output of the California mercury mines exceeded 50,000 flasks per year; in 1909 it had fallen to less than 16,000. Formerly the metal went in carloads to Montana and Mexico; today the smelter and the cyanider have driven out the old-time amalgamator; and yet the value per flask has kept on a fairly constant level. This has been due to the decrease in the grade of ore, and to increase in the cost of production. Despite the fact that California is still full of promising prospects of mercury ores, capital has been averse to competing with the established producers when they are confessedly in uncertainty as to the future.

The price for a few months was on the ascendant, reaching a maximum of $51 per flask. It has now dropped back to $47.50. The improvement in price was in answer to heavy demands from Germany and Russia, which began toward the end of 1909. The shipments made to those two countries were approximately 1500 and 1000 flasks per month for a considerable period. The object of these importations was obviously to manufacture fulminate, and the motive was therefore at bottom political. This demand has now subsided, and the market drops. The manufacture of fulminate is one of the chief uses of mercury today. A classification of the consumption cannot be made with much reliability, but the demand, in order of quantity, is for amalgamation, for making fulminates, for mirror plating, for thermometers and other philosophical instruments, and for pigments. In the early days large shipments were made to China for conversion into vermilion; this trade has now wholly ceased.

The quicksilver market is today under control of a virtual monopoly. As in the case of so many other metals, the house of Rothschild exercises a dominant influence, but the business in none is guarded with such secrecy as in mercury. The most acute observers of production are unable to trace the inflow and outflow of the stocks held in London by this great firm. It can dictate prices, and it does. Until some new use shall be found for this metal the Rothschilds will determine the quotations. It is interesting to note, in this connection, that the E. I. du Pont de Nemours Powder Company is preparing to deliver itself from market uncertainties by becoming a producer of quicksilver. This, at least, will have the good effect of encouraging the manufacture of fulminate in the United States. The metal is protected by a duty of 7 cents per pound, which is the salvation of mercury mining in this country, but it happens to work against the making of fulminate. A large proportion of that substance used here is made in Canada, using quicksilver imported from England. The entry of the powder companies into the arena as producers would, however, affect the present miners of that metal to no small extent.

Mining and Aviation

By A. E. Berriman*

Mining engineers, of all people in the world, have reason to pay close attention to modern progress in aviation, for in connection with mining it is already possible to imagine a field of utility for the aeroplane in its present state. For the time being the aeroplane happens to be a plaything of the rich—so was the motor car, ten years ago. Such a lesson in the rapidity of twentieth century progress naturally makes for an optimistic outlook on the future of flight and although it does not justify the inane faith of those who 'suppose' that flight will soon supersede every other system of locomotion, it at least rebukes the equally thoughtless comment, "what's the use of a machine like that," which is too frequently the remark of those whose minds are unable to grasp more than the obvious disproportion that now exists between the great size of the flyer and the dimensions of the man it carries.

Flying has not yet taken its place as a recognized system of economic transport in the realm of commerce but undoubtedly it is on the threshold of that domain. It only awaits the man who shall arise and show his fellows how to apply the new found art to the furtherance of some industry wherein it may serve a useful purpose. Undoubtedly, such men will in good time come forward—mayhap the mining engineer will be among the first. He is a man whose work leads him far from the traces of civilization, into corners of the earth where roads and railways are only conspicuous by their absence, oftentimes into places whose topography unfortunately maintains their isolation even while their mineral wealth causes them to permanently harbor a community of men. Who among traveled mining men is as familiar with the awkward situations of such mines as is the mining engineer, and who has not realized the drawbacks of the narrow line of communication by which they are in physical touch with the world at large? What a godsend the telegraph and telephone have been in breaking down the absolute character of the barrier by which isolated centres of life would otherwise be imprisoned. Yet the electric wave does but convey a thought and how often, in this material world, does it not happen that more substantial goods need transport? What an advantage it would be, upon occasion, to possess the means of traveling quickly from a mine to the nearest town; to discard tortuous mountain paths and to go straight 'as the crow flies' through the air.

Four hundred years ago a few men dreamed of such things, Leonardo da Vinci was one of them. One hundred years ago a few men still pondered on the problems of flight, Sir George Cayley was one of them. Twenty years ago an aeroplane first rose from the ground, in it was Ader of telephone fame. Three and a half years ago Santos Dumont won the first flight prize by flying 25 metres under official observation. More than a year elapsed before Henry Farman succeeded in flying round a circular course of only one kilometre in length, but eight months afterward Orville and Wilbur Wright had each flown for over an hour at a stretch. That was in September, 1908, since when about 50 pilots have achieved flights of over 60 minutes duration, several of them remaining aloft twice as long. The English channel has been crossed without touching water and cross-country journeys of over 100 miles in extent have been carried out without touching the ground.

Admittedly these latter are not ordinary exploits, but this does not detract from the importance of the fact that the present state of the art has already been developed to a degree of real utility. Any modern aeroplane might be used to perform a journey of 30 miles with reasonable certainty of success. There is, today, sufficient evidence to warrant a mining engineer seriously considering the air as a path of economic locomotion where natural difficulties interfere with the use of terra firma to the best advantage. A year ago such a thought would have been deemed a mere poetic wish; how long it has passed from the realm of imagination it would be difficult to say. Many readers believe it to be there yet, but one day they will surely read in the Mining and Scientific Press that "—— have an aeroplane at the —— mine and are using it for special journeys to —— which is 20 miles distant across difficult country." Then they will realize that the aeroplane is a vehicle of locomotion even in its present imperfect state, and they will no longer wait for some luxurious 'Aerial Century Limited' any more than the pioneer users of motor cars waited for the coming of the motor 'bus.

Doubtless the introduction of the flying machine into the realm of mining is involved with many difficulties and needs not a little pluck; but doubtless, too, the first man who carried on traffic in a boat upon the waters was considered before his time. Nor must it be supposed that the successful use of the atmosphere in one place and for a certain purpose necessarily implies that it affords a universal solution to the problem of economic transport. The wheel, even in its simplest form, has proved such a wonderfully efficient device for reducing the co-efficient of traction that it makes quite indifferent conditions of transport on land many times superior, on this score, to those obtaining with the 'aerial sleigh'. The resistance to motion in terms of the load is in the order of 2% on decent roads and 1% on rails. In the air the resistance to horizontal flight is in the order of 15%; an amount that is comparable with the resistance offered by a sand road.

On the other hand the air goes everywhere and affords a ready made path direct to the goal. It involves no capital outlay and no expenditure on maintenance. It can be traversed at any speed and as the co-efficient of flight resistance is independent of velocity, a very high rate of travel in a flying machine suitably designed for the purpose would not be attended by such disproportionate increase in the expenditure of power as occurs with marine navigation.

The modern aeroplane in its biplane form carries about 500 sq. ft. (total) of supporting surface on two decks having a span of about 40 ft. Equipped with a nominal 40-hp. gasoline engine such a ma-

*Technical Editor of *Flight*, London.

chine weighs about 800 lb., and is capable of carrying in horizontal flight an additional load of about 350 lb., of which about 200 lb. is represented by the pilot and fuel; thus leaving a surplus lift of 150 lb. to support a passenger or a dead load. Such figures are mere approximations, but they serve as some indication of the present order of things. In mountainous districts the necessity of flying up hill and in rarified atmosphere would involve special consideration, but, just as it would be proper to regard a journey of 30 miles as lying within a practical range, so would it be reasonable at the present time to plan to carry a useful dead load in the order of 100 lb. These are not, perhaps, very encouraging figures but they at least represent a margin of utility. It is probable that many a mining engineer has known occasions when he would have been more than glad of the opportunity of getting even a smaller load transported 30 miles in an hour, which is in the order of modern flight speeds, and it is conceivable that many situations now exist that would justify the capital expenditure of $5000 (aeroplanes cost anything from $2500 to $7500 at the present time) and the wages of the pilot.

It is always difficult to illustrate a general argument of this character by a specific example, but every mining engineer will be able to call to mind cases in which merely being able to get up in the air and look around would have been invaluable. It may sound a little far fetched to suggest an aeroplane as part of the equipment of a prospecting party, but imagine what advantages would accrue if it were shown to be possible. Paulhan, the famous aviator, is in the habit of using a camera while he flies and if such pictures could be taken successfully of strange ground they would surely be useful. But, even if these things are in themselves rather remote, much progress may nevertheless result merely from having the utility of the atmosphere recognized and the minds of mining engineers turned thereto. The aeroplane is not the only aerial machine—when the wind blows it might be worth while trying to use a man-lifting kite.

Alaskan parties of the United States Geological Survey are already taking the field. G. C. Martin will investigate the Matanuska coalfield. Adolph Kopf will make geologic surveys in the Juneau-Berner's Bay region. U. S. Grant will work on Kadiak Island. A. G. Maddren, with a topographic party under R. H. Sargent, will be in the Innoko-Iditarod region finishing the season on the headwaters of the Kuskokwim. P. S. Smith will study the Koyukuk region, going as far as Kobuk. D. C. Witherspoon and F. H. Moffit will survey the south flank of the Alaska range with headquarters at Susitna. At the same time J. W. Bagley and S. R. Capps will work on the north side of the range. A. H. Brooks will visit several of the parties in July. L. M. Prindle will remain through the season in the Washington office.

Unless otherwise expressly stated therein a covenant in a mining lease to mine the premises continuously will be taken to mean continuously to the end of the term for which the lease is granted.

Genesis and Classification of Mexican Onyx

By E. M. Lawton

One of the products of Mexico now coming into popular use in the United States for decorative building purposes is the so-called Mexican onyx. Strange as it may appear, various eminent geologists are at variance with regard to the genesis and formation of this interesting product. While it is a deposit frequently found in the Sierra Madre range in Mexico, yet without doubt the opportunities for studying its character and origin are not so easily found in other parts, which compels the evolution of a theory, rather than the actual study which the opportunity in Mexico affords.

Real onyx is, of course, a variety of chalcedonic quartz, but instead of classifying it as a silicate, one is accustomed to think of it as akin to the agate or carnelian. In fact, ancient writers, such as Pliny, have considered it a semi-precious stone, and it has been much used in making cameos. This is the true onyx, but Mexican onyx has a different composition and origin.

Dana declares it to be calcite ($CaCO_3$), with rhombohedral structure, while the American Encyclopedia says that it is aragonite, which would necessarily be an orthorombic crystal and without the cleavage of calcite, although with the same chemical symbol.

I have been engaged in developing onyx-marble quarries in Mexico, and have hesitated to advance an opinion in the face of the differences between eminent authorities, but the metamorphism is so apparent and clear in the simplest study of these deposits that it should be easy to classify the rock and determine its origin. In the quarries in question, being those of Etla in the State of Oaxaca, the surface or capping is a blue limestone which is used by the natives in making an excellent quality of lime for mortar. On removing this capping, streaks of a crystalline onyx are found, and this mixture of limestone and onyx continues until a decided slip is encountered, of a soft white stone almost like slacked lime in appearance, but much harder. This white band usually marks the solid deposit of onyx-marble, but even in the solid blocks are frequently found portions of yet unchanged limestone.

The change from limestone to aragonite (for its lack of cleavage would certainly eliminate calcite) is undoubtedly a paramorphic change which is simply a crystallization, resulting from the disintegration of the lime rock by the seepage of the surface waters, decomposing the solid rock into the white semi-powdered form, until a thin line of crystallization commences. This is gradually added to, not unlike the stalagmitic growths in caves, until the whole mass is disintegrated and crystallized. Certain it is that it is not formed by deposition from hot solution or from vapors, for the formation is even now going on. Nor could it be a deposit in pools, for it occurs in the high mountains and on the hill slopes, where the topography and the form of the deposit will not admit of such an assumption. It has been suggested that it might be formed in this manner also, by the

filling up of caverns, which seems equally untenable. Frequently pockets of clear, perfectly sweet water are found hermetically sealed in the onyx, the sides of the pockets being studded with the small crystals peculiar to caverns where lime water is dripping.

The quarry development gives perfect examples of the various stages of the mineral change. To a student of geology it is worth a long journey to investigate this. It is to be hoped that it may be studied at no distant date by some one more able than myself.

OUR ANNIVERSARY

Numerous letters and telegrams have been received congratulating the MINING AND SCIENTIFIC PRESS on its fiftieth anniversary. From among those read at the dinner given the staff at the Palace Hotel May 21, the following extracts may be of interest:

I had hoped to be able to comply with your invitation and write a special article for the number of the MINING AND SCIENTIFIC PRESS commemorating its fiftieth anniversary; but the Jubilee Celebration at the University of California and pressing duties connected with the closing term have made it impossible for me to do so. I cannot refrain, however, from sending a word of greeting on this occasion. Semicentennial anniversaries are so rare in a new State like California that they are more marked epochs here than they would be in an older community.

Some of my earliest boyhood recollections are associated with the columns of your paper. I can well remember the very vivid impressions made upon my youthful mind by its descriptions of wonderful processes for extracting gold from its ores and of machinery for extracting the ore from the earth. Looking back over its pages, it is interesting to see how the minds of the inventors of each period were busy in working out every possible variation of some theme characteristic of the period. Methods of placer and hydraulic mining came first; then gold and silver, quicksilver and copper (vein) mining followed in their turn; amalgamation processes of every kind—the Mexican arrastre, the patio process, battery and plate amalgamation, the use of sodium amalgam, pan amalgamation, with the employment of every conceivable chemical, have been described in your pages. Then followed methods of concentration of sulphide ores; the development of the chlorination process in all of its various forms; then your pages were filled with accounts of the hyposulphite leaching processes for many years, just as now they are largely devoted to the cyanide process.

The origin of your paper harks back to the period before the introduction of engineering art and scientific methods into the mining and metallurgy of our country; and almost the entire history of the development of the American mining and metallurgical art may be traced through the back numbers of your paper. They are, in fact, a veritable museum of curious methods and processes, many of them long since abandoned; but some of these nearly forgotten descriptions contain living germs of useful ideas which, falling on fertile soil, may even yet bear fruit. The pages of the MINING AND SCIENTIFIC PRESS have always been clean; they have never been for sale. And through its darkest hours it has always kept an honorable name. It has always come very close to the working miner—more so than any other mining paper in the world. It is found in every mining camp west of the Rocky Mountains, and is read and quoted all over the mining world. Its pages have constantly grown in value, and particularly since Mr. T. A. Rickard took charge of the paper it has taken a position quite in the lead of the times. May its future be as bright as its past has been honorable!

S. B. CHRISTY.

I regret exceedingly that I will not be able to attend the dinner to be given on the occasion of the fiftieth anniversary of the founding of the MINING AND SCIENTIFIC PRESS. I have followed this paper now for forty years of its existence, and so certainly feel that it is an old time friend. I wish it all the success possible in the future and that it may celebrate fifty more fiftieth anniversaries.

JOHN B. FARISH.

I am very much pleased to get your letter of May 10, inviting me to the dinner on the 21st to celebrate the fiftieth anniversary of the MINING AND SCIENTIFIC PRESS. I am sorry to say that it will be quite impossible for me to go down on this occasion. However, I send you herewith my felicitations on the event, and hope you will all have a good time.

J. R. FINLAY.

I had hoped to be present at the California celebration, and then at yours, but I am held here and cannot get away until some time in June. I hope to see you some time this summer. With best wishes for the celebration and the future, and congratulations for the way the editorial staff is keeping up and improving the PRESS.

C. F. TOLMAN, JR.

I do not expect to be in town on that date. I shall leave this city *Deo volente*, Thursday morning next, not to return until after you shall have finished your celebration. Thanking you sincerely for the courtesy of your invitation, and with compliments of the season to the MINING AND SCIENTIFIC PRESS.

CURTIS H. LINDLEY.

I regret very much that I will not be in San Francisco at the time of this function. As this letter will reach you after the date of the anniversary, I can only add what probably has been said many times at the function, that I wish you another fifty years of uninterrupted prosperity.

J. PARKE CHANNING.

Wish I could be on hand May 21 to celebrate the golden anniversary of the PRESS, but there is no chance of my being in the West before next month at the earliest. With kind regards and best wishes to all connected with the PRESS.

F. LYNWOOD GARRISON.

I am sorry not to have been able to be in the city at your anniversary jollification. Please accept congratulations on your anniversary number. It is worthy and valuable.

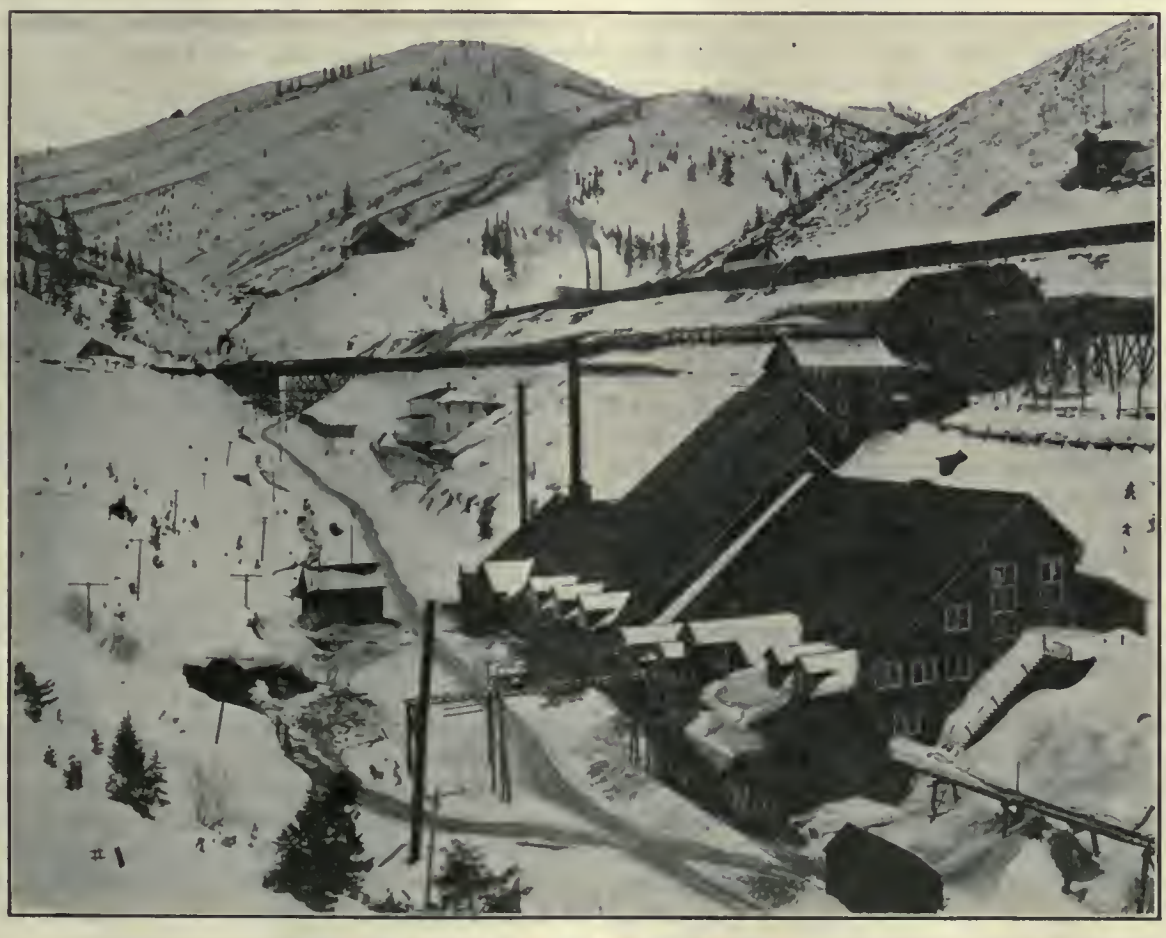
HORACE V. WINCHELL.

Park City, Utah

STAFF CORRESPONDENCE

The Daly-Judge mine at Park City, Utah, is shipping 25 tons per day of first-grade ore and is concentrating 150 tons. The mill ore runs 6 to 9% lead, 4½ to 9 oz. silver, 6½ to 12% zinc, and 10% iron. The mill work results in concentrating 3½ tons into 1, the zinc-iron concentrate being sold to the Grasselli Chemical Co., which has a plant at Park City; the lead-silver product is shipped to the smelting plants in Salt Lake valley. The high-grade ore probably will run 20 to 27% lead and 25 to 35 oz. silver, though some shipments have run as high as 70 oz. silver and 4 to 5% copper, with a corresponding increase in lead. The mine originally was opened by a vertical shaft, 1650 ft. deep, and later by a transportation and drainage tunnel which starts in Empire canyon, running 6600 ft. southwesterly to the shaft at its 1200-ft. station. The tunnel is equipped with electric haulage facilities. Through this avenue the miners go to and from work, and the ore is hauled out to the mill and shipping bins. The fuel and other supplies for the steam plant are taken in this way and hoisted to the collar of the shaft, 1200 ft. above the tunnel level. The shaft-house contains a double-drum steam-hoist, installed in 1891, and four steam boilers. A Nordberg air-compressor, installed last January, having capacity of 2100 cu. ft. of free air per minute is run by a rope-drive from a 350-hp. electric motor, the compressor having a constant speed of 87 r. p. m. The motor is of General Electric make. It derives its power from the Snake creek power plant; the current, coming over the transmission line at 6600 volts, is stepped down to 440 at the compressor plant.

The mine workings open three veins on the property. The Ontario-Daly fissure strikes northeast and dips northwest. To the depth of 1500 ft. this is a fissure in the limestone; below the 1500 it becomes a contact vein between limestone and quartzite. The Middle vein, 1000 ft. southeast, almost paralleling the Daly fissure, is a bedded vein between a limestone hanging wall and a quartzite foot-wall. This is the vein from which the old Anchor company obtained most of its ore. The Black vein, still farther to the southeast, has more of an easterly strike than the Ontario-Daly, and dips nearly south, the hanging wall being limestone and the foot-wall quartzite. All three of the veins named are important, and the ore-bodies therein are well developed. The Ontario-Daly is entered on the 1200-ft. level by a short cross-cut from the shaft, connecting with a 2600-ft. drift running southwesterly along the vein, but keeping within the foot-wall. Raises No. 2, 3, and 7 have been made on the vein from this drift and stoping is in progress. The stopes off raise No. 7 are 10 sets high, the width being 30 ft., but the vein matter is accompanied by considerable waste. A cross-cut which starts from the Ontario-Daly fissure some 2000 ft. from the shaft runs easterly to the middle vein, opening into the main drift on the latter, which connects with a cross-cut running east from the shaft; thus establishing a circuit for ventilation as well as ore haulage. Several raises have been made from the



Daly-Judge, Park City, Utah. Entrance to Main Tunnel on Left

1200-ft. level on the Middle vein, one of these being raise No. 1, which is up 80 ft., a stope therefrom showing a good body of ore. The same cross-cut that runs east from the shaft to the Middle vein has been extended on to the Back vein, connecting with drifts on the latter. All the foregoing relates to the 1200-ft. level. Starting from the 1400-ft. station of the shaft, a cross-cut has been run to the Ontario-Daly fissure, and another cross-cut has been driven in the opposite direction to the Back vein, about 2000 ft. distant. From the 1500-ft. station connection is made with the Daisy stope on the Middle vein, the main body of the ore being iron, but within are narrow seams of ore carrying lead, silver, and gold, one 5-ton shipment of which ran $138 per ton. The Back vein has likewise been opened by a 1500-ft. level. A connection was made from the 1600-ft. station to the Ontario-Daly fissure some years ago, but as all workings below the 1500-ft. level are now under water that part is not accessible. It is understood that the stronger bodies of ore on this main fissure are to be found at and below the 1600-ft. level, where the lime-quartzite contact begins. The Back vein, which averages about 10 ft. wide from wall to wall, accompanied by a lot of waste, is opened on higher levels from the 700 down to the 1500-ft. The mine work is superintended by R. T. Mason.

A Starrett mine pump having the capacity of 800 gal. per minute, operated by compressed air, is set just below the 1500-ft. station, raising water through a 4-in. pipe part way, then through a 6-in. pipe to the drainage channel on the 1200-ft. level. It is said an 8-in. column should be used to get full capacity. This is a new type of pump, made in Salt Lake, and is said to work admirably. A large flow of water, which drains the higher channels on the Ontario-Daly fissure, is arrested on the 1200-ft. level and diverted to the drainage tunnel, thus preventing it from sinking to the 1500-ft. level and adding to the volume which has to be pumped to unwater the lowest workings. George W. Lambourne, general manager for this company, states that a contract has been let to Free & Taylor, of Salt Lake, to drive a 14,000-ft. drainage and transportation tunnel, starting from Snake creek, on the opposite slope of the Wasatch range, cutting into and draining the Daly-Judge ground to a depth of 1800 ft. below the collar of the shaft, and 600 ft. lower than their present transportation tunnel. This project is being undertaken by the Snake Creek Mining & Tunnel Co., composed of Jesse Knight, H. O. Hanke, G. W. Lambourne, T. F. Bayard, and others.

The Daly West mine, also at Park City, is producing every 24 hours from 350 to 375 tons of milling ore and 20 tons of first-grade. The mill ore, which is taken mostly from the 1500, 1700, and 1800-ft. levels, carries approximately 10% lead, 15 to 18% zinc, and 14 oz. silver. The product obtained by the efficient concentrating methods employed in the mill consists of a lead concentrate running 40 to 45% lead, 35 to 38 oz. silver; and a zinc concentrate carrying 40% zinc, 4 to 5% lead, and 15 oz. silver. The first-grade ore, shipped to the smelting plants without concentrating, is taken mostly from the stopes between the 900 and 800-ft. levels, and contains 70 to 80 oz. silver per ton, and 22% lead. The mill ore is hoisted to the collar of the shaft, trammed over to the mill and dumped into the bins; the first-grade ore is landed at the 1200-ft. station, and from there taken out through the main haulage-way to the shipping bins at Park City. The shaft is 2100 ft. deep, at the base of which is a 500-ft. cross-cut through which connection is made with the great Ontario drainage tunnel, and by which this mine is thoroughly drained. The great fissure, from which most of the ore is obtained, stands at a dip of 70° north, has a limestone hanging wall and a quartzite footwall, the strike of the contact being northeast-southwest. There are a number of parallel fissures in the quartzite, each branching out from the main fissure at an acute angle. These subordinate fractures are especially apparent on the 1500 and 1700-ft. levels, and where they join the main fissure there occurs a distinct widening of the latter and a corresponding expansion of the orebody. In some cases the ore extends 20 to 30 ft. from the principal lode into the minor fissure. On the 1700-ft. level the main drift in ore has a length of 757 ft., the average width of ore being 15 ft. The greatest width at any point is 30 ft. The face of this drift is in ore, and E. L. Talbot, mine superintendent, anticipates that it may be continued hundreds of feet farther. Extensive stoping is in progress above the 1700-ft. level, and to carry on this work advantageously a double chute and manway has been put in every 50 ft., with an intermediate chute between. The body of ore in the stope 100 ft. above the 1700-ft. level, off No. 6 raise, seemed 30 ft. wide and free from waste. This stope has been carried up 14 sets, stringer sets of 10 by 10-in. timbers being used. No. 6 raise, now up 100 ft., is being extended up to the 1500-ft. level. A winze has been sunk from the 1700 to the 1800-ft. level, following the dip of the vein; and a 317-ft. drift in ore has been run from the bottom of this winze on the 1800-ft., which at present is a blind level. A cross-cut is being driven from the shaft at the 1900-ft. station to open the main fissure and establish what will be the 1900-ft. level. This cross-cutting has progressed 587 ft., the remainder of the distance to the fissure being 800 ft. Eventually, when the 1900-ft. level shall have been made, a winze will be sunk from blind 1800 to the 1900. These facts serve to illustrate Mr. Talbot's method of development and of obtaining good ventilation. The orebody on the 1700 seems wider than that on the 1500-ft. level. The ore found on the 1700 and 1800-ft. levels shows an increase in the zinc content without any diminution in the lead content, but with possibly a slight decrease in silver. The hoist, air-compressor, and mill machinery are all steam driven, the steam-boiler plant having an aggregate of 1000 hp. The coal for boiler fuel is brought in through the main haulage tunnel to the 1200-ft. station of the shaft, then hoisted on the 3-deck cages to the collar of the shaft and dumped into the bins adjoining the boiler house. Hand instead of mechanical stoking is employed. The mill concentrate is brought to the shaft in cars, lowered to the 1200-ft. station, thence hauled out through the transportation tunnel to the shipping bins.

Fifty Years in Cornwall

By Thomas Rickard

Introductory. First and foremost among the improvements of the last fifty years are doubtless the Bickford & Smith safety-fuse and Nobel's invention of dynamite. Let those who may be disposed to doubt ask the old miners how it fared with them when, as yet, they were compelled to fire with the rush or the goose-quill filled with rough powder and with a sulphur wick for train; ask them how they did when sinking their flooded sumps without the invaluable waterproof safety-fuse. The loss of life and limb through miss-fire, and the consequent necessary clearance of the holes for renewal of charge, was appalling in those days. Decidedly their friends Bickford & Smith will deserve to rank with Abel and Humphrey Davy among the canonized in the miner's calendar. The electric spark for firing belongs to the same order of beneficent inventions, but though invaluable and indispensable for certain kinds of engineering, such as railway and marine and sometimes in mine work, it is not much employed in ordinary mining.

In minor particulars, if indeed, they may be called minor, such as the expeditious removal of the débris, the hoisting and conveyance to the battery or the dump, there is also improvement. In the better equipped mines not only are the rail-gradients, the shoots and tips, in better order than formerly but the cage has replaced the 'kibble' and the trucks (the Decauville side-tip) are of excellent construction; moreover, the endless rope-and-clamp conveyor—of Kimberley type—may be observed in working perfection. In this group of operations the advance is evident and labor-saving devices are being pursued in a manner that is of excellent augury.

It is, perhaps, to be regretted that some better kind of light has not superseded the candle. The acetylene lamp is in occasional use, but, not being favored by the miner, it is rarely adopted. Next in order of efficiency comes the rock-drill, with the air-compressor, which, under certain circumstances, is an invaluable boon to mining. It would be well if financial considerations oftener favored its use in opening up wider fields of exploitation. It is noteworthy, if not disappointing, that as yet the electric drill has not been brought within the domain of the practicable. Though tried in many places, notably in America and Scandinavia, it has yet to be proved a success.

Faith in 'dowsing' as the prospector's means of diagnosing his ground, though not dead, is almost extinct. It survives sporadically and it has been my luck to encounter adepts in the craft ready to offer their dubious services on conditions intended to be seductive. With their hazel twig these picturesque survivals appear as if taken from the wood-cuts of Agricola. The determination of the site of ore deposits by the magnetic needle, not infrequently practised elsewhere with good effect, is seldom practicable in the case of ordinary lode formations and only when ore masses are magnetic. The hopes created some years ago by experiment in mines in the United States have not blossomed. In this field of work the dowser's hazel twig is still foremost in disputing precedence with diamond-drilling.

Ordinary transport by road is nearly in the same condition as fifty years ago, though only a decade earlier the country was yet without the boon of a railway. In the days before the railway it was not uncommon to meet mule-trains packing the 'tinstone' from the mine to the mill; the latter being in some place favored with water for power and other purposes. It seems hardly credible that the Duchy of Cornwall, the motherland of the expert tinner, should in this particular have been so recently in the same category with Spain, Mexico, or Sicily, as regards cross-country conveyance. But so it was, though the county even fifty years ago could boast of having excellent highway communication, but more in the western than in the eastern half of the peninsula. In fact, East Cornwall to this day cannot be said to excel in its roads.

Drainage. In pumping there is little actual improvement to record though there certainly is much to indicate that important changes are impending. The revolution that was expected from the introduction of electrical pumping has yet to be realized. Experiment, of which there has been abundance, has hitherto been marked with disappointment and failure, though the reason for failure remains a puzzle. That the electric pump would not work so economically as the old arrangement was easily enough foreseen, but why there has been so great a fiasco is difficult to understand. It was at least to be expected that, properly applied, the electric pump would speedily drain any of the old mines, and that, too, with less plant outlay than is otherwise necessary, but such has not been found true. Despite many attempts and frightful expenditure, the pump is yet in the stage of experiment. In this respect, pumping, to all intents and purposes, is as it was half a century ago. Seeing what has taken place in other mining regions of the world it may safely be predicted that a new order of things is destined to prevail in Cornwall also, and this prediction is largely strengthened by the great economy that attends the adoption of the producer-gas engine. Power generated by the use of this engine and transmitted from the nearest coalfield will probably have to be employed for the drainage of the deep mines of Cornwall. But even then the engineer who may undertake this change will have no easy task to perform, for he will have to compete with the direct-acting engine, working with almost perfect condensation and wonderfully capable of control in speed and degree of expansion, and working with a consumption of only 2½ lb. coal per hp. hour. The consumption of coal in most foreign mining districts, except now in France, is oftener 5 to 7 lb. than 2½ lb. per hp. hour, and in many places it is four times more than in Cornwall with the beam engine.

By the way, may it not be said that had the unrivaled performance of the perfected beam-engine as left to us by the engineers of the 'fifties' and 'sixties' been better understood it would have been better for Cornwall and for those who have so recklessly spent their money on the hitherto almost fruit-

less experiments in electrical pumping. With this, as with the attempt to realize profit by the treatment of the dumps of the old copper mines, there has been lamentable lack of sound judgment. During the spacious times of the 'fifties' and the earlier 'sixties' the Duchy was happily supplied with good technical intelligence in all its branches. In my world-wanderings since those days I have failed to meet with industrial activity of any kind that can be said to be carried on with better ability or greater zest than that of mining in Cornwall. In future we shall hear less of primitiveness of methods in the county.

I confess to surprise that engineers in Britain are so slow in appreciation of the place in mining equipment to which the gas-engine has attained. In the south of France, for instance, this engine is in general use and the ordinary steam-engine and boiler are scrapped all along the line; the economy is immense. I also wonder that mining engineers generally in Britain should seem to be unaware of the success with which the induced-current pump or hydraulic elevator has been employed. I have used it with marked advantage, and without doubt, it is destined to play an important part in the drainage of mines.

Dressing. I choose to retain the term 'dressing', for, like the *aufbereitung* of the Germans, it is often more expressive than the 'milling' of the Americans or the *traitement mechanique* of the French. Decided improvement in stamping has resulted from the tardy introduction of the Californian gold-quartz mill, from the invention of the pneumatic battery, and from laudable attempts in other particulars. I think, however, that the improvement is often exaggerated, for, although the Red River 'streamers' are less happy in their gleaning operations, I fail to learn that there has been any marked saving in labor, and it is said that the tin oxide does not go to the smelter in cleaner condition than formerly, but rather the contrary. It is worthy of note that the California battery may be seen at work alongside the Cornish type that it was supposed to supersede, and on the same mine the pneumatic stamp is also at work. Batteries of these three contending forms mingle their thunders. At some of the mines, for instance, Dolcoath, East Pool, and Wheal Kitty, the old form of mill has made way for the pneumatic battery. This would seem to indicate that the survival of the fittest in the way of tin-dressing equipment in its essentials will henceforth be the pneumatic stamp at one end and the perfected automatic frame table at the other, with varying devices filling the requirements between. Here some are found clinging to the buddle in one or other form, while others are partial to the continuous percussive table as well for the finer sand as the slime. The choice of appliance for the functions of this intermediate stage is, of course, regulated in accordance with the varying nature of the veinstuff but as yet no device is in the field by which the 'framing' can be discarded.

Among the least susceptible of advantageous change is the dressing that follows the calcination of the tin croppings in order to rid them of the pyrite elements. The immemorial 'stripping, keeving, and deleuring' is, in most cases, still the practice, though in some few mines—Crofty, for instance—the percussive table has been adopted for performing the same purpose.

Conspicuous among improvements is electro-magnetic separation. It has done excellent service in such mines as East Pool, Clitters, and Crofty, where the tinstone is associated with wolfram. By this apparatus a product that formerly corrupted, and greatly depreciated the value of the tin concentrate, is made a valuable subsidiary source of profit. Mention may be made of the improved saving of the arsenic. Crofty affords a brilliant example in this particular as the extraction of the wolfram.

Saving of Residue. The Red River problem, in spite of all kinds of ingenious devices that have been applied to it in endless succession during generations, is still unsolved and save for some remedy rather of a chemical than mechanical nature it seems well-nigh insoluble. It is true, however, that wastage is less than fifty years since, as is proved by the fact that the 'streamers' along the course of the effluent waters are not so happy as they were. It is well to bear in mind that the contents of the ore going to the mill is reckoned in pounds of tin per ton of ore. Ore of 2% yield, or 40 lb. black tin per ton, is considered good. Many of the mines yield ore of a lower average even than this, some, indeed, as in the St. Agnes district with less than 1%. Closely examined the cassiterite is so finely distributed that it is barely detectable and that portion of it released by calcination seems almost imponderable. As to much of the tinstone from the deep mines, one may well wonder that the extraction is so good. To those who may be curious as to the manner in which the wastage is traced in the course of dressing, I would commend the excellent article by H. W. Hutchin appearing in *The Mining Magazine* for April, 1910. This 'bleeding' of the ore in the dressing is likely to continue to be a serious handicap; and with this unavoidable wastage at one end and the onerous royalties and the barbaric way of levying them at the other, the miner is often fated to struggle for what looks like the unattainable.

It may be necessary to submit to the inevitable in the matter of wastage by dressing but to have to pay 6 to 9% of the value of the gross output, often irrespective of its being won at a loss or profit, is a cruel hardship. Verily this is a millstone round the neck of the miner. I have before me the latest account rendered by Dolcoath mine, from which it appears that out of the gross profits—amounting to £17,683—the landowner's share is nearly £5000 or about 35%! The published account of the profits of the company show that in some years the landlord's portion was greater than that of the shareholders'. When will the landowners of Cornwall in their methods of levying royalties now so barbaric, be brought into line with those of other leading civilized countries, where the landowner is content with 5% of the earned profit? This is the well known custom in all the leading continental countries, save, perhaps, in the Sicilian sulphur mines which are subject to papal administration.

Other Industries. To the fifty years belong the pitch-blende discoveries, or, shall we say, the excite-

ment of hopes by the attempt now so laudably being made in this connection under the guidance of public-spirited scientists and engineers. Although not yet demonstrated to be in the domain of industrial success, the prospects are fascinating. Note must be made also of the recent attempt to extract gold from the sea-water, for, though unsuccessful, the experiments have at least made it more than ever conceivable that the water when treated in larger volume may surrender its gold profitably. The china clay industry, which has attained the vast proportion of nearly 1,000,000 tons per annum, is undeniably profitable and expanding. So important is the trade in this commodity that it has not infrequently acquired an importance superior, as an industry, to everything save agriculture. There is little to record in change of working methods either in the getting of the clay or the reduction of the felsite for clay, save that, in some cases, the clay is piped to the coast, and there has been some experimenting with the vacuum-filter. China clay together with floriculture has largely compensated Cornwall for the collapse of the once famous pilchard fisheries. Decidedly Cornubia has many resources and is a wonderful country. It has survived many an apparently moribund condition and will survive many another.

Present Conditions. But when all is said of the improvement in methods and appliances, the fact remains that with tin in demand at over £150 per ton, or, say £90 for 'black tin', few mines are in operation, and of these it may scarcely be said that any are in a really flourishing condition, in spite of a large expenditure supposed to have been primarily for underground development and general preparatory arrangements. This provides a comment the reverse of flattering on the innovations and improvements in drainage and dressing methods, of which so much has been heard during the last decade. Formerly £60 per ton for black tin was considered altogether satisfactory, but now with £90 a pervading note of discouragement is observable. Nobody seems to be happy or even hopeful. This certainly is not what was expected by those who have parted with their money to vivify tin mining nor by those who advise it. In hard reality there are few more ungrateful propositions in mining than that which faces the tin miner of the present day in Cornwall. Doubtless the difference in respect of the cost of labor accounts to a large degree for the depression. The workpeople, it seems, do less work than formerly, while receiving nearly twice as much pay. It is generally said by the managers, and scarcely disputed by the men themselves, that compared with fifty years ago the day's work is less though the pay has nearly doubled. Formerly it was £3 per calendar month, whereas now it is 25 shillings per week. In most cases labor represents 40 to 60% of the total cost. The increased cost of labor is, therefore, approximately £30 per ton of black tin, if won at £60. The men seem to have lost that interest in the welfare of the master and his mine though more pains are taken in respect to their health and safety and to make their lot generally more tolerable.

The murderous ladder-way, which in deep mines was attended with great danger and frightful loss of vital energy, is a thing of the past, nor do you often see the miner at the face toiling with his candle placed horizontally to keep it alive in bad air. In the struggle for existence the miner has been driven by the frequent lack of employment to far-off countries, where he finds a welcome and much better pay. Only the aged and the youthful remain at home. The service has suffered in quality and the attachment to home industry has declined. It will take a long time to remedy this, if, indeed, it is fated ever to be remedied. Finally, the retrospect of Cornish mining, in the 50 years since the MINING AND SCIENTIFIC PRESS was founded, provokes one broad conclusion, namely, that while technical methods have improved this improvement has not been inadequately translated into economic results.

PLATINUM IN SOUTHEASTERN NEVADA

By HOWLAND C. BANCROFT

*At the Key West and Great Eastern prospects in the Copper King mining district of Clark county, Nevada, platinum occurs in peridotite dikes of the enstatite-mica-pierite variety. The properties are situated in the rough foothills of the Virgin range at an elevation of approximately 3600 ft. and are eight or nine miles from the Virgin river. The rocks in the immediate vicinity are gneisses, probably of pre-Cambrian age, and are intruded along the planes of schistosity by basic dikes which contain, in addition to platinum, primary pyrrhotite (probably nickeliferous), magnetite, chalcopyrite, and pyrite. Besides the periodotite dikes there is also present a typical hornblendite dike which shows upon analysis a trace of platinum. Alteration and concentration of the sulphides in the rock by solutions seems to increase the percentage of platinum and nickel, one analysis showing the presence of 0.55 of an ounce of platinum per ton and over 5% nickel. The dikes as exposed upon the surface vary in width from 10 to 50 ft. and are about 100 ft. long. One carload of ore has been shipped from the Key West workings.

Mexican mineral production in 1909, according to the latest Boletin de Estadistica Fiscal, Mexico, has been unusually large. The production of gold amounted to ₱45,015,000, as against ₱38,096,661 of the previous fiscal year. Other factors were: silver, ₱77,110,000; copper, ₱20,283,000; lead, ₱6,397,000; zinc, ₱1,043,000; iron, ₱1,200,000; coal, ₱4,400,000; mineral oil, ₱2,800,000; other minerals not classified, ₱2,052,158. This is the best showing ever made by Mexico and speaks well for her future development. The mineral resources of the country are as yet hardly touched, it being estimated that less than 1% of the known prospect is being worked. The gold output of Mexico in 1890 amounted to ₱2,000,000. In 1896 it had reached the value of ₱10,000,000, and in 1903 it exceeded the sum of ₱20,000,000. The output of silver in 1909 reached the tremendous total of 2,191,199 kilos (one kilo equals 2.2 lb.), the largest on record. The present depression in the price causes it to show a slump of ₱8,000,000, ₱85,446,904 being realized in 1908.

*Read before the Geological Society at Washington and abstracted in *Science*.

Improvements in the Cyanide Process

By Bernard MacDonald

The fact is generally recognized that the only important improvement made in the cyanidation of gold and silver ores during the last five years has been in the mechanical manipulation of the ore-pulp during treatment, and, in the methods of recovering the metals brought into solution, and that the chemistry of the process has remained practically unchanged. The sum of the mechanical means and methods that have been developed and improved during this period, omitting the numerous details of manipulation, may be set down as: (1) Stamping through coarse battery screens. (2) Classification and de-watering of the battery product into sand and slime. (3) Fine grinding (sliming) the sand. (4) De-watering (thickening) the slime-pulp. (5) Treatment of the slime in high tanks by air-lift agitation. (6) Recovery of the solution from the treated pulp by filter-pressing. (7) Precipitation of the gold and silver from the solution by zinc-dust.

In Mexico where the tonnage of silver ore treated by stamp-milling and cyanidation is greater than in all other mining regions combined, and where the largest part of this tonnage is of very low-grade ore, every new design promising greater economy and efficiency has been adopted and used.

The high royalties charged by proprietors of patent devices used in the processes have furnished the incentive if not imposed the duty upon all mining engineers charged with the design of new plants to evolve other methods equally as effective to accomplish the same purpose, hence the number of filter-presses and variety of design of other equipment now on the market. The result is competition and a choice of machinery that makes for cheaper and more efficient plant, with correspondingly greater economy of operation, making possible the profitable treatment of lower grade ores.

A recent improvement in tanks for the treatment of slime-pulp is shown in the accompanying figure, for which United States Patent No. 948,766 and Mexican Patent No. 9948 have been issued. I believe this tank to be a great improvement over any hitherto used in the treatment of the slime-pulp of gold and silver ores. This tank, with its special equipment, is known as the 'Parral' tank, a sectional view of which is seen in the figure. The main improvements in this tank are: (1) The division of the tank-bottom into two or more pockets or compartments of inverted conical or pyramidal form, made of wood or steel partitions. (2) A charge-pipe extending from the top of the tank, and terminating in nozzles placed at the apex of the bottom-compartments through which the pulp-charge entering the tank passes, and is delivered under the pressure of the hydrostatic head due to the height of the charge-pipe over the pulp-level in the tank. (3) Two or more transfer-pipes set at or near the sides of the tank, and extending from the bottom to the top of the tank, having the lower ends resting on the tank-bottom, but open, so as to admit the entrance of the pulp which settles to the bottom of the tank for transfer through these pipes and delivery on the top of the tank-charge.

These methods of charging the pulp into the tank and of transferring to the top of the charge the heavier particles as they settle secures an intimate admixture of the cyanide solution and the pulp-particles which is necessary for bringing the contained metals into solution. This type of tank equipment makes it possible and even desirable in large milling plants to use treatment-tanks each having a holding capacity of 300 to 400 tons of dry pulp, for these tanks may be made of any diameter and any height warranted by local conditions, as the full charge of pulp can be treated with efficiency and economy equal to that in the ordinary small tanks.

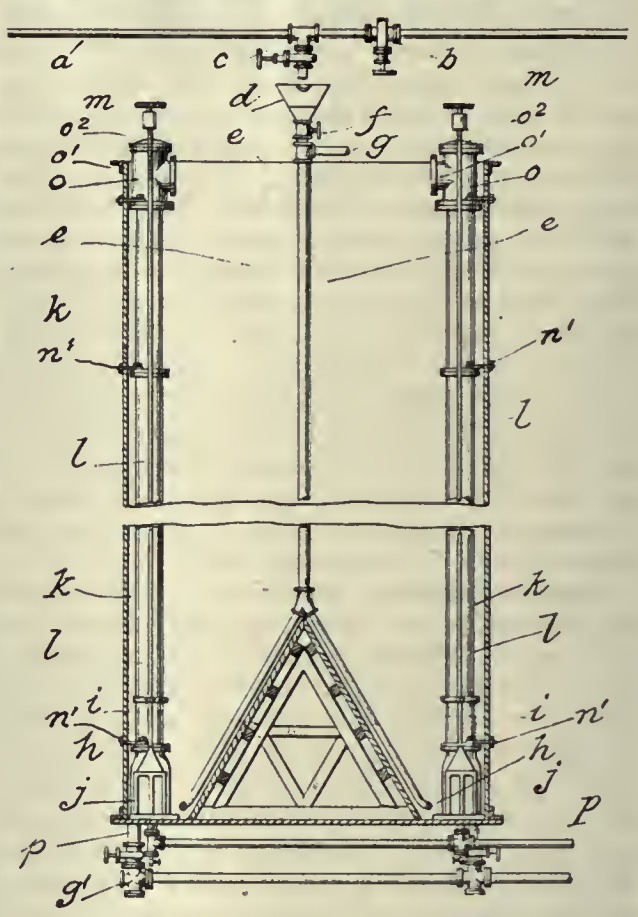


Fig. 1.

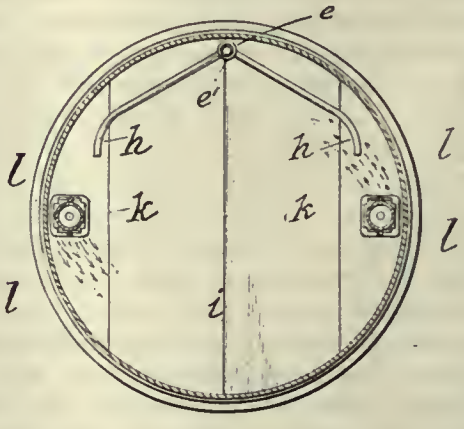

Fig. 2.

In operation the tank receives the charge of pulp for treatment through a charge-pipe of any suitable

diameter which may be placed within or without the tank, according to local conditions. The pulp passing downward through this charge-pipe is delivered through branches terminating in nozzles, one nozzle at the apex or bottom of each of the two or more pockets or compartments built on the tank-bottom, as shown in the figure. The pulp being thus charged enters these compartments through the nozzles under hydrostatic pressure which creates sufficient agitation to prevent settlement of the pulp-particles on the bottom of the tank. However, to prevent the possibility of pulp settlement on the bottom of the tank, provision is made for the admission of compressed air or cyanide solution under pressure at the bottom of these compartments through the same nozzles. This gives any desired amount of agitation. The charge-pipe at its intake at the top of the tank is provided with a receiving hopper, or funnel, having a screen bottom. The chemicals necessary to bring the solution contained in the pulp-charge up to working strength are weighed and placed in this hopper periodically, as required, and the pulp being charged into the tank flows over and through them, dissolves and carries them in solution with it as it is injected into the bottom of the tanks through the terminating nozzles of the charge-pipe.

The advantage of this method of under-feeding the pulp which is charged into the tank, and having it intimately mixed with the required strength of chemicals freshly brought into solution, as compared with the open feed on the top of the charge, which allows the heavier pulp particles to settle out of the associated solution to the bottom, leaving the latter on the top, is apparent.

This treatment-tank is designed to receive its charge of pulp directly as delivered from the pulp de-watering (slime thickening) tanks, and thus it fills the functions of a collecting and treatment tank simultaneously. When the tank has received its full charge the agitation necessary to complete the treatment by bringing the valuable metals into solution, is begun. This is effected through the two or more transfer pipes referred to, one for each of the compartments into which the bottom of the tank is divided. These transfer pipes are firmly supported on the bottom of the tank by open foot-pieces of suitable design. Through these foot-pieces compressed air is introduced to the transfer pipes in an upward current, which effects the rapid transfer of the pulp from the bottom of the tank, and its delivery at the top of the charge. The top or delivery ends of the transfer pipes are fitted with tees, or ells, placed at such an angle that their delivery outlets are in the same direction and circumferential to the sides of the tanks. The force of the pulp thus being delivered on the top of the charge imparts to it a whirling motion which carries the pulp particles in a spiral course around the tank in their settlement toward the bottom. When they reach and settle into the apex of the bottom compartments they are again picked up and carried through the transfer pipes and delivered on the surface of the charge, and the agitation is thus continued until the treatment is complete. It is reasonable to believe that this whirlpool motion disentangles the heavier pulp-particles from the colloidal material in the pulp-mass in which they may be imprisoned, exposing them to freer contact with the chemical solutions, and thereby hastening the extraction of the metals they may contain. It is also considered that a plurality of transfer pipes of smaller diameter can be operated with greater economy than one large pipe of equal area. The reason for this belief lies in the fact that compressed air, in order to be effective as a lifting agent in a submerged pipe, must form in discs, the circumference of which must touch the sides of the transfer pipes and thus travel upward through it, while if the transfer pipe be of large diameter the compressed air will rise as bubbles through its centre and have no more lifting effect on the pulp contained therein than if a rod were rammed up through the centre of the pipe. The bubbles of compressed air merely take a zigzag upward course through the pulp which fills the column, leaving it to remain balanced in equilibrium with the pulp or liquid in the tank outside the transfer pipe. Of course, this equilibrium can be overcome by the injection of a sufficiently large volume of compressed air to fill the transfer pipe so that air may form in discs extending across the pipe, no matter what its diameter may be, but this is wasteful and expensive.

The lifting action of compressed air in a submerged pipe-column is effected by a complete intermittent cut-off or separation of the liquid in the column, from the liquid outside it, by air discs, as described. Separate bubbles, no matter how many, rising through the transfer pipes have no more lifting effect on the pulp contained than the ascending bubbles in a glass of champagne has on its contents. To be effective for this purpose the air must form in discs wholly across the transfer-pipe, in which form they act as the piston of a pump, each disc separating and completely cutting off a certain amount of pulp from the mass in the tank outside and carrying this amount with it as it rises to the top. The number of such discs formed per minute is analogous, in lifting effect, to the number of piston-strokes of a pump.

As stated before, one of the main advantages of the 'Parral' tank is that the apparatus with which it is equipped makes it possible and even desirable to build it of larger dimensions than would be commendable in the use of one central transper pipe. A tank 15 ft. diam. (which is the limit for a treatment tank with one transfer pipe) by from 45 to 47 ft. high is the average of the largest treatment tanks in general use, and has an approximate holding capacity under ordinary consistence of pulp of 100 tons of dry slime, while a tank of equal height and 30 ft. diam. would have a holding capacity of 400 tons of dry slime of similar consistence. It will be readily seen how the larger tank with four bottom compartments, or pockets, and four transfer pipes, placed around the sides with their intake ends opening into the apex bottom of these pockets would effect equally as good agitation and treatment as would be the case in a tank of 100 tons capacity with one air-lift transfer pipe, while the economy in extraction and operation per ton would be an item of considerable importance.

Annual Labor Pending Patent Proceedings

By H. W. MacFarren

The proeess of patenting or obtaining the fee title to mining claims held by loeation or possessory right may be divided into three steps or stages. (1) The application to the surveyor-general of the land district for an official patent survey, followed by the field work of the deputy mineral surveyor, and it in turn by the checking and approval of the survey by the surveyor-general and his official filing of the notes and plat. (2) The filing of the approved survey with the local United States Land Office, together with an application for mineral patent to the land embraced in the survey, followed by all the various proceedings, including opportunity to adverse claims, required by the Land Department in its efforts to see that the laws are complied with and that the rights of other miners are protected. (3) The entry for patent by paying the purchase price for the land at the local Land Office and receiving therefor the receiver's certificate, or receipt, to be exchanged for the patent upon its issuance.

By the first step the applicant acquires no further right to the ground, beyond that contained in his possessory right, than such additional constructive right as the better marking of his claim and the official filing of its exact position and boundaries may give. However, it gives some benefit in that it will throw the burden of adversing any conflicting ground upon subsequent numbered surveys, unless there is undue delay in proceeding toward patent. There is also the further safety given by the officially marked posts. No compulsion upon the claimant exists to proceed further toward patent.

Prominent in the second step is the filing of adverse claims against the proposed patent by those who claim the ground or portions of it by other and adverse locations to the one entered for patent. Adverse claims must be filed at the local Land Office during the sixty days of publication of the notice of application for patent. They may be fought out in the courts later. Also prominent in the second step is any protest made by the Government at the instance of its employees or of private parties against granting the patent on the ground that the Federal statutes, and the regulations of the general Land Office, have not been complied with. The protests may be initiated at any time after application for patent and up to its issuance, to be fought out before the Register and Receiver of the local Land Office.

After the adverse suits and pending protests have been disposed of and the local Land Office is able to ascertain what ground the applicant is entitled to under the law, he is allowed to take the last step of making final entry and receiving the Receiver's receipt in temporary lieu of the patent document which will arrive later from Washington.

The status of the claim with reference to performing the annual labor or assessment work during the second and third step—the steps for obtaining patent proper—has been defined by the decisions of the Land Department, and it is believed that the courts will be guided by the principles they have laid down. The statute says "on each claim located * * * and until a patent has been issued therefor, not less than one hundred dollars' worth of labor shall be performed, or improvements made, during each year." The Land Department has recognized that there is usually great delay in issuing the patent, and in its receipt by the applicant; consequently it holds that the date of final entry, of paying the purchase price, and of receiving the Receiver's receipt, may be taken as the date when patent issues so far as annual labor is required. The Land Department has also recognized that final entry cannot always be made immediately after the expiration of the period of publication, since adverse suits and protests often drag out for a few years, but until these are settled it cannot allow final entry. To require the applicant to perform annual labor during the period within which patent is withheld by these suits would be unjust, and in consequence it holds "the length of the interval between the end of the period of publication, or the finality of pending adverse suits in court or protest proceedings in the Land Department, and the date of final entry, is immaterial, so long as entry is made before the close of the then current calendar year; and the principle with respect to the completion of the patent proceedings is the same whether the time remaining to the applicant within which to make entry as aforesaid be only a day or several months." (32 L. D., 200.)

From the above and from other decisions of the Land Department it is apparent that should the period of publication expire December 30, and there should be no adverse suits or protests pending, it would be necessary to make final entry the next day —before the close of the calendar year—if no annual labor had been performed that year, to keep them from being open to location on or after January 1, unless work was immediately resumed and carried into the next year. Should an adverse or protest be pending, no work would be necessary for the closing year. Should these litigations be undecided during the new year, no work would be required; but for the year in which they would be decided and settled, entry would have to be made on or before December 31, or work be performed, whether the litigation ended January 30 to December 30. Where entry does not immediately follow as prescribed, the applicant, when he does make entry, will be required to show that no re-location of the claim has been made, or if there has been material delay, to make a new application for patent.

After entry no annual labor is required except where the Receiver's receipt is cancelled on grounds of fraud. The question arises, is a re-location made by a party adverse to the applicant for patent, and based on the non-performance of the annual labor for the preceding year, and in the belief that patent will be refused on grounds of fraud, such a location as the refusal of patent will validate? The Land Department has said, "a location under the mining laws made upon land not at that time regularly subject thereto, because covered by a subsisting though invalid entry, may nevertheless, if maintained in

good faith and the land subsequently becomes subject to location, be permitted to remain intact, as being attached on such date (date of cancellation), if at that time there is no adverse claim." (33 L. D., 30.)

In a case where patent was refused for reasons that did not reflect on the good faith of the applicant, but where a new application was required, the applicant was protected from forfeiting his claim through having left undone the annual labor. Where the applicant for patent through negligence does not proceed to entry within the required time, but is not guilty of fraud, there is little reason for believing that a re-location made before the expiration of the year in which entry should be made, and based on failure to do the annual labor for the previous year, could be validated by failure to make entry, that is, a valid re-location could only be made after the expiration of the entry-year, and in case no labor had been performed for the previous or closing year.

The following rule may be deduced: if the application be based on an attempted compliance with and obedience to the law, and it is intended to make entry as soon as allowable, the annual labor need not be performed for the year in which the period of publication ceases or thereafter, provided entry is made within the year in which the adverses and protests are settled and the entry becomes allowable. In short, annual labor need not be performed for the year in which publication ceases or thereafter, provided final entry be made during the year in which such entry becomes allowable.

DROP SLUICES

By Dennis H. Stovall

Almost every manager of a hydraulic mine on the Pacific Coast admits that he loses, or fails to save a large amount of the gold in the ground. This loss is due to the fact that fully 25% of the gold is associated closely with black sand. This is the fine or 'flour' gold. Because of the lightness of the sand and the fineness of the gold it is practically impossible to save them by riffle and sluice. They simply refuse to settle and lodge, and are carried to the dump and lost. Numerous methods have been tried, and appliances of every description employed, in this work. Experience has proved many of them worthless; in fact, the more complicated the machines, the less efficient they are in saving the gold. One of the best means employed for securing the fine gold is that of drop-sluices or undercurrents. These are easily built, require no attention save that of cleaning once a month, and can be installed at little expense. One such system, placed on the Old Channel mines of the Galice district, is shown in the accompanying illustration. This saves an average of 30 oz. of gold per month during the operating season. This is gold that would otherwise be lost, as it is taken from the extreme end of the sluices. The undercurrents are two in number, each taking its water and concentrate from two different points on the line of the sluice. One is placed four box lengths from the end of the sluice, the other, one box from the end, and, being near the dump, they give the boxes and riffles every possible chance to save the gold before dropping into the undercurrents. These are merely single or double riffle tables set by the main sluice, the water and concentrate being drawn through a grizzly plate and delivered by an adjustable gate, whence it spreads over the table. The fine gold settles on the table, over which burlap is spread to serve as riffles. The grizzly on the sluice bottom is made of ½-in. iron bars, 3 or 4 in. wide, set edgewise ¾ in. apart. It should have a length of 5 ft. and a width equal to the width of the sluice. Beneath the grizzly is placed a cross-sluice into which the water falls and is delivered immediately to the upper end of the undercurrent. As stated, this flow is regulated by a drop-gate.

Undercurrents Attached o Sluice.

Once a month the burlap is lifted off, rinsed in vats of still water, and replaced. A few hours work is all the attention required. The undercurrent tables should be at least 10 ft. wide and 15 long, with burlap coverings made to fit. A drop of 8 in., or as little as 6 in., is ample. It should be enough to allow a smooth and even flow of the water and sand over the riffles. If the miner does not care to use burlap he can build the undercurrents with riffles already provided. This is done by constructing the floor of two-by-fours, setting them edgewise, every alternate plank being dropped down ½ in. To clean these, the water is shut off, just enough being allowed to flow over to assist in the work, and the concentrate collected with a pan and broom. The amount of flow over the undercurrents can be regulated only after several trials. The miner will soon learn, however, just how much to admit through the grizzlies to give best results.

Ferrobamba Limited is the name of a company recently formed in London to take over copper mines situated about seventy miles from Cuzco, Peru. The properties were reported on by W. E. Gordon Firebrace, who claims that the mines contain millions of tons of 8 to 9% ore and also a reasonable tonnage of bornite and chalcopyrite on hand. The address of the London office is 638 Salisbury House, London Wall, E. C. The capital of the company is £120,000, of which £20,000 is to be spent for development, it being the intention to increase the capital later on to £1,000,000 and to build a railway from the mines to Cuzco and also to build a large smelter. However, even if the orebodies are proved, it will take about four years to complete the railway and the smelter.

MINERAL PRODUCTION OF CHILE IN 1908 AND 1909

By F. A. Sundt

The 'Estadistica Minera de Chile', Vol. IV, years 1908-1909, has recently been issued by the Sociedad Nacional de Mineria and from it I quote the following figures of the mineral production of Chile.

1908.

	Quantity.	Value.
Gold (fine), gm	1,188,522	$1,070,354
Silver (fine), gm	52,435,071	1,515,241
Copper (fine), kg	42,096,731	27,156,579
Manganese ore, kg	1,000	20
Lead in silver-lead ore, kg	9,722	360
Ores for collection, kg	3,433	5,025
Saltpetre (NO_3Na), met. tons	1,970,974	215,033,296
Iodine, kg	330,090	3,928,071
Potassium perchlorate, kg	54,500	21,800
Borate, kg	35,039,038	4,905,465
Salt, kg	1,625,700	812,873
Sulphur, kg	2,704,722	324,567
Sulphuric acid, kg	797,000	79,700
Guano, kg	870,800	83,173
Coal, met. tons	939,836	13,157,704

1909.

	Quantity.	Value.
Gold (fine), gm	1,268,414	$1,175,569
Silver (fine), gm	44,282,578	1,039,099
Copper (fine), kg	42,726,145	26,477,516
Manganese ore, kg	.....	.....
Lead in silver-lead ore, kg	1,200	104
Ores for collection, kg	.....	.....
Saltpetre (NO_3Na), met. tons	2,101,512	208,470,040
Iodine, kg	474,209	5,571,850
Potassium perchlorate, kg	92,220	56,888
Borate, kg	32,218,042	4,510,526
Salt, kg	2,046,300	1,023,132
Sulphur, kg	4,507,707	540,925
Sulphuric acid, kg	1,415,000	141,500
Guano, kg	10,691,845	425,058
Coal, met. tons	898,971	11,686,623

The most remarkable fact which may be deduced from these figures is the increase in copper production in both years. Since 1884 there has been no such copper output. The increase as compared with the average for fifteen years past amounts to more than 12,000 tons. This is due to new mining companies operating in Chile, such as those of Collahuasi, Antofagasta, the French companies of Catemu, Naltagua, Chañaral, and others. All of the copper is produced by smelting. There are nine plants with converters. The average grade of ore smelted is about 8 to 10%. The only concentrating mill-plant is at Rancagua, owned by the Braden Copper Co., but it is as yet producing but little. There are two small lixiviating plants. Sulphuric acid is produced at Guayacan smelter by matte roasting and the catalytic process. Nearly 80% of the acid is consumed at the copper-leaching plants. It is probable that the production of Chilean copper will increase next year because European capital, especially French and German, is interested, and the Braden Copper Co. is erecting a new mill to treat 2000 tons of 3 to 4% ore per day.

The production of gold is stationary. Silver has shown some increase as compared with preceding years. Gold and silver are principally treated by amalgamation. There is no cyanide mill in Chile, although many ores refractory to amalgamation have been proved capable of being treated by cyanidation. Gold and silver in copper bars is not refined here. There is practically no production of lead because the copper mines attract the capital.

Production of nitrate of sodium is increasing yearly, but prices are not so good because consumption does not increase at the same rate. Saltpetre deposits are large; enough for 100 years more is known. Pig iron and steel do not appear in production for 1908 and 1909, but the blast-furnaces of Corral have been put in blast this year, using wood (not charcoal) as fuel. The coal mined is all consumed in the country, and one million tons more is imported. Water-power is singularly abundant and favorably situated, and it is being used more and more.

Application for patent to mineral land must be accompanied by a filing fee of $10 and the following papers: (1) A notice which states claimant has filed an application for patent for the claim, and describes it as the field notes, with the exception that the description is condensed. The notice should be signed by the applicant and witnessed by the two witnesses who were present at the posting. This must be at some conspicuous point on the claim, where it isposted with one copy of the plat. (2) Proof of posting notice—The two witnesses who were present when the plat and notice were posted execute an affidavit stating the time and describing the place at which they were posted. (3) Agreement of the publisher—The agreement of the publisher of the paper in which the notice will appear must state that he will make no claim against the United States for the publication, but will look to the claimant only. (4) Location notice—A certified copy of the location notice on which application is made must be procured from the county recorder in whose office it is recorded. (5) Abstract of title—The abstract must be certified by the county recorder in whose office the records appear, and the patent will issue to those shown to be the owners of record at the time the application was filed. (6) Plat and field notes—These consist of one of the plats and the field notes received from the surveyor-general. The application is made and sworn to by either the claimant or his attorney-in-fact, and in addition to the matters in the notice, contains a statement of the claimant's citizenship, his source of title, and specific information as to the area of claim and the price he paid for it, as well as the character, extent, and value of its ore deposits. These papers are all filed with the register and receiver of the United States Land Office in the district where the claim is situated. One copy of the notice is by the register forwarded to the paper for publication, and one copy posted in the land office.

Five 'Parral' tanks, each 25 ft. diam. and 42 ft. high, having a holding capacity of 300 tons of dry pulp under the usual solution-consistence for treatment, are being erected at the milling plant of the Veta Colorado Mining & Smelting Co., at Parral, Chihuahua. The apparatus was designed by Bernard MacDonald as an improvement over existing types of agitation tanks, and he believes that they mark an important forward step in the mechanical improvements of the cyanide process.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Regenerating Copper Cyanide Solution

The Editor:

Sir—In reply to R. P. Wheelock's statement in your issue of March 12, I beg to acknowledge an error in my explanation of February 5. The same result is obtained in restored cyanide, 80% or better, even if an excess of acid were used. I meant that the acid solution should be neutralized with lime before titrating for KCy. What I meant by saturated solution was solution enriched as much as possible with Au + Ag + Cu values before precipitation. By going to excess with acid and causing precipitation, the chemicals will float all the coagulated precipitates to the surface of the solution. These precipitates will remain there if the gas be not expelled. I do not mean, however, to say that the potassium cyanide cannot be restored even if an excess of acid has been added. To cause complete precipitation as Mr. Wheelock did, a small proportion of the solution being taken and filtered and acid added to the filtered solution, it is evident that enough has been used if it does not turn turbid.

Some contend that $^3/_{10}$ of 1% of copper sulphate is fatal to a working KCy solution. On that point the following test is instructive: take 1000 c.c. H_2O, add 5 gm. KCy + 10 gm. copper sulphate; slack and grind CaO to 60-mesh, add to convert the K_2SCuCy solution from green to blue. Before the copper sulphate is added to the KCy solution add a known amount of gold, say, at the rate of $20 per ton. Take one assay ton of the filtered solution from the blue; precipitate the Au and Cu; restore with $Ca(OH_2)$; and note the saving of copper and gold and also the restoration of KCy. Filter off a portion of the CuCy solution before $Ca(OH_2)$ is added and read the contents for copper volumetrically; repeat this with the filtered solution after $Ca(OH_2)$ is added and note the results. Test the KCy restored solution for active service by agitating with gold leaf or pulp. A 5-lb. KCy solution, restored or fresh, should dissolve leaf-gold in four minutes when well agitated.

A sulphur-bearing KCy solution can be made that cannot be read with silver nitrate but is still active toward gold, silver, and copper; it may be regenerated. The sulphur can be liberated so that it can be read with $AgNO_3$ by precipitating the sulphur with copper or silver, thrown in solution and precipitated with H_2SO_4. I claim all solutions should be properly treated with lime before precipitation by either the acid or the zinc method. When Cu is present in the working solution my experience is that lime is not added in excess if carbonate of lime does not predominate on the surface of the solution like thin ice after standing six hours or over night on pulp.

In one case I have used 40 lb. of lime to one ton of ore. I did not simply use it to neutralize acid, as we were taught a few years ago, but to take care of the iron, zinc, and other salts as well. A pulp practically alkaline may take 10 lb. of lime. When copper is in solution and is being precipitated on zinc shavings, they are gray or brassy looking. If more lime be added they will change to black and will feel silky.

Referring to Mr. Wheelock's copper-acid-cyanide precipitate, my experience has been that such precipitate from a working solution consists of 40% copper, the balance being sulphur, lime, gold, silver, and a small percentage of cyanates.

I will later send data explaining a case where it takes 26 days to enrich a solution in its gold, silver, and copper content, a method applicable to decanting or percolating. Some of Mr. Wheelock's methods I would like to test, but have not the materials at hand. I have never enriched the solution pound for pound in copper, nor have I ever obtained a precipitate containing 50% cyanogen. It cannot be done if the solution or pulp had been properly treated with lime. Whenever the KCy is broken up by adding H_2SO_4 either in small quantity or in excess, it can be restored by calcium hydrate, but one cannot break up the KCy by adding copper sulphate if the proper amount of lime is present. The KCy will not pick up any more copper, gold, and silver than it will precipitate, or, in other words, it will precipitate all it picks up or a fraction thereof by adding H_2SO_4. The lime protects the potash and allows restoration of 80% or better.

ISAAC ANDERSON.

Prescott, Arizona, March 31.

James Annual Cyanide Letter

The Editor:

Sir—In Mr. James' annual letter on cyaniding in your issue of January 1, he gives a list of different filtering machines with the percentage of recovery of dissolved metal values and costs. The table is headed by the Ridgway with 99.5% recovery, which may be so; but I think the figure is excessive. On the Associated Northern mine we found that when everything was in good order, 95% of the dissolved gold was the average recovery; at the Associated, it was not quite so high; and at the Perseverance about 97%, and, although I have no data on this point from other mines, yet it is doubtful whether 99% would be the average, even with efficient washing. I am not trying to depreciate the working of the filter-press by any means, as it will hold its own here against the vacuum process; but poor washing does go on in the press at times, even when conditions are good for high recovery. The two vacuum plants at work on old dumps in Kalgoorlie, are not doing such extra good work, although the residue being treated is rather refractory. With reference to graphite in cyaniding, Mr. James says that "roasting is the natural remedy." My article on this subject in the MINING AND SCIENTIFIC PRESS shows that this is not the case, and I have had very good opportunities of studying it. Graphite comes through the roasters unchanged, although perhaps a very small percentage may be burned. Mr. James is partly right when he mentions exposure to the sun. We found that,

when the extraction was low on account of graphite, a residue assaying, say, $3 per ton, when re-mixed with sump solution of 0.04 KCN, pumped into a filter-press without any agitation, and washed for only ten minutes at 75-lb. pressure, yielded a final residue would be as low as 70c. to $1 per ton. In most cases, this did not need exposure to the air for many hours, although longer exposure gave a higher extraction at times. Graphite is a peculiar mineral to deal with, and being such a staple thing, it needs much study.

M. W. von Bernewitz.

Kalgoorlie, Western Australia, March 15.

Yerington Rock Names

The Editor:

Sir—In the number of your paper of March 5 there is a re-print in part of Bull. 380 of the U. S. Geological Survey relating to the Yerington copper district. In that bulletin there is a review of a paper by myself. The title of the paper reviewed is the 'Geology of the Upper Region of the Main Walker River, Nevada'. It was written in 1904, and since there is omitted from both the bulletin and the re-print certain antecedents relative to formational terms and rock names, it is thought a note of explanation to the popular reader would not be out of place. I could not communicate with you sooner because my notes were not at hand.

In the bulletin referred to it is said: "This assemblage of rock was called by Smith the 'bedrock complex', a name which it is not desirable to perpetuate." The term is ascribed to geologists of the U. S. Geol. Surv. (Becker, Turner, and Lindgren). The term appears in 'The Pyramid Peak Folio No. 31, 1896 and 1897', seven years before the appearance of the paper reviewed, and it has been used when referring to formations elsewhere in the region of the Sierra Nevada; and when it is said that "it is not desirable to perpetuate" the term, it is evident that subsequent detail work has led the Government geologists to revise their classification. The other objection was to the rock names, and it is said "the granodiorite or monzonite rocks were by him (myself) designated 'granite', 'granite-porphyry', and 'porphyrite', although his own petrographic descriptions appear hardly to suggest these names." The Survey issued a bulletin in 1897, No. 150, which was calculated to be "valuable to educational institutions for the purpose of teaching." The terms granodiorite and monzonite were omitted from it, but the first term was given by Becker in 1891, six years before the bulletin made its appearance, and the second term (monzonite) by de Lapparent in 1864, 33 years before. I found that the terms in Bull. 150 were not satisfactory and did not fit the material in hand. I then referred to some English and German petrographers, and, as all classifications are more or less artificial, I found names that came closer: although not altogether satisfactory, they were used, trusting that the descriptions would be sufficiently accurate to convey a notion of what the rocks are. If accurate names had been available I would not have given so much space to that sort of thing.

D. T. Smith.

Virginia City, Nevada, May 14.

BUREAU OF MINES BILL

Be it enacted by the Senate and House of Representatives of the United States of America in congress assembled, That there is hereby established in the Department of the Interior a Bureau, to be called the Bureau of Mines, and a Director of said Bureau, who shall be thoroughly equipped for the duties of said office by technical education and experience and who shall be appointed by the President, by and with the advice and consent of the Senate, and who shall receive a salary of $6000 per annum; and there shall also be in the said Bureau such experts and other employees as may from time to time be authorized by Congress.

Section 2. That it shall be the province and duty of said Bureau and its Director under the direction of the Secretary of the Interior to make diligent investigation of the methods of mining, especially in relation to the safety of miners, and the appliances best adapted to prevent accidents, the possible improvement of conditions under which mining operations are carried on, the treatment of ores and other mineral substances, the use of explosives and electricity, the prevention of accidents, and other inquiries and technologic investigations pertinent to said industries, and from time to time make such public reports of the work, investigations, and information obtained as the Secretary of said department may direct, with the recommendations of such Bureau.

Section 3. That the Secretary of the Interior shall provide the said Bureau with furnished offices in the city of Washington, with such books, records, stationery, and appliances, and such assistants, clerks, stenographers, typewriters, and other employees as may be necessary for the proper discharge of the duties imposed by this act upon such Bureau, fixing the compensation of such clerks and employees within appropriations made for that purpose.

Section 4. That the Secretary of the Interior is hereby authorized and directed to transfer to the Bureau of Mines from the United States Geological Survey the analyzing and testing of coals, lignites, and other mineral fuel substances and the investigation as to the causes of mine explosions; and the appropriations made for such investigations may be expended under the supervision of the Director of the Bureau of Mines in manner as if the same were so directed in the appropriation acts; and such investigations shall hereafter be within the province of the Bureau of Mines, and shall cease and determine under the organization of the United States Geological Survey; and such experts, employees, property, and equipment as are now employed or used by the Geological Survey in connection with the subjects herewith transferred to the Bureau of Mines are authorized to be transferred to said Bureau.

Section 5. That nothing in this act shall be construed as in any way granting to any officer or employee of the Bureau of Mines any right or authority in connection with the inspection or supervision of mines or metallurgical plants in any State.

Section 6. This act shall take effect and be in force on and after the first day of July, 1910.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Aluminum is produced commercially from bauxite and cryolite only. It occurs chemically combined in kaolin and a number of other minerals, but no economical method of reducing it has been discovered.

Work on a mining claim for patent need not be done on the claim itself provided the claim participates in a common improvement, such as a shaft or tunnel, which actually benefits the claim in question to the extent of $500.

During 1908 the United States drew its supply of vanadium mostly from the highlands of Peru, where are large deposits of a peculiar carbonaceous sulphide of vanadium known as patronite. These deposits are reported to be controlled largely by the American Vanadium Co. of Pittsburg.

Sodium-amalgam can readily be prepared electrolytically. Special cells for this work can be purchased from dealers in chemical apparatus. Essentially the method consists in passing an electric current through an acidulated solution of common salt in contact with a cathode of mercury. The salt is decomposed, the sodium following to the cathode, where it amalgamates with the quicksilver. At the same time chlorine gas is disengaged, and escapes from the solution.

The supporting power of a pile, two-thirds of which is in the ground, can be determined by the formula given in Baker's 'Masonry Construction',

$$P = 100\ (\sqrt{Wh}\ (50d)^2\ 50d)$$

in which P is supporting power in tons; W, weight of the hammer, in tons; h, height of fall, in feet; and d, penetration of the pile under the last blow, in feet. The test blow must be measured on sound wood, and it is best to use the average of several blows.

Assessment work done outside of the surface boundaries of a mining claim leaves open a question of fact whether the work so done tends to the development of the claim or not. The purpose for which the work is done, if questioned, must always be manifested by the relation which it bears to the claim itself. If the plan pursued can have no reasonable adaptation to its alleged purpose the mere assertion that it was pursued for that purpose will not suffice, even though good faith be conceded.

Water issuing from a spring on a mining claim belongs to the owner of the claim as long as he maintains the validity of his title. The owner of the claim can prevent a subsequent adverse entry on his claim and appropriation of the spring itself, but cannot prevent anyone from lawfully appropriating below the claim whatever water may run from the spring and issue in a defined water-course on adjacent land, and which has not already been devoted to some beneficial use by the owner of the claim.

Lead-chlorine vanadate, vanadinite, and related minerals, endlichite, descloizite, and others, occur in the oxidized zone of lead-bearing veins in Montana, Colorado, New Mexico, Arizona, California, and other States. Some of these ores have been produced commercially in New Mexico and Arizona; but most of the minerals mined have been sold to the smelters for their lead content. The principal known vanadium deposits of this country are at Newmire, near Placerville, Colorado, where the mineral occurs as roscoelite, a green vanadium mica in the soft La Plata (Jurassic) sandstone. The vanadium content of the ore does not exceed two per cent.

The early giants were swung by block and tackle from side to side. A workman attempting to clean his shovel by holding it at the side of the nozzle accidentally discovered that this deflected the giant. From this was developed first the sleeve and then the double joints now in use. Giants were made with a 9-in. butt and tapered nozzle which was 8¾ in., under a pressure of 460 ft. Washing flumes were also increased to, say, 6 ft. wide, some on as heavy a grade as 18 in. to the box 12 ft. long, some using paving blocks 14 in. deep. Some iron riffles, and some stones of large size, paved the bottoms of the flumes, and where sufficient grade was had large undercurrents were employed to save the fine gold.

Double-ended quartz crystals, magnetite, and many other minerals in their highest state of mineralogical perfection both as to form and purity, and garnets and other precious stones, frequently occur as secondary or accessory minerals. It is interesting to note that certain well known brands of hones or sharpening stones consist of slates or shales full of microscopic garnets or other hard minerals. Garnets are so common in these and other rocks, and in the gravels, produced by their natural disintegration, as to scarcely deserve the title of precious stone, although the beauty of those of good color almost equals that of the ruby. Owing to their hardness, garnets are largely used as abrasives, and probably nearly 10,000 tons of true garnets whose only fault is that they are 'off color' are ground up for that purpose annually.

Oil must be actually discovered by drilling a well and striking oil to validate a placer location applying to oil. Mere oil-seepages and surface indications are not sufficient. Of course, the evidence might in an extreme case be sufficiently convincing to justify a discovery without drilling, but the courts have not yet had such a case called to their attention, and it is doubtful if anything but actual drilling and striking oil would satisfy the courts. A locator must proceed diligently with drilling until he makes a discovery. Ordinarily he is protected only to the extent of the ground which he actually occupies in his drilling operations, and a rival locator may take peaceable possession of another portion of the same location, in which event it becomes a race between the rivals, and he who first discovers oil becomes entitled to the claim. The locating and patenting of oil claims is provided for by the law applying to placer mining.

Special Correspondence

LONDON

Flotation Processes.—Sulphide Corporation.—Sulitjelma Copper.

Flotation processes are comparatively unknown in the United States, a fact which is incomprehensible to me. There are many ores and tailings in various parts of America giving trouble to the metallurgists and miners, and judging by analogy with results obtained in other parts of the world, they should prove amenable to flotation. There are several of these processes, more or less modifications of each other, but the Elmore vacuum process at present takes the lead in successful application. Two notable examples of the plant are to be found at the Zinc Corporation works, where Broken Hill zinc tailing is treated, and at Sulitjelma, Norway, where copper-bearing tailing beneficiated.

The Zinc Corporation was formed by Bewick, Moreing & Co. in 1905. The first processes adopted were not successes and the company's financial position became serious. Finally the Elmore vacuum process was adopted and the company is now a dividend-payer as far as the preference shares are concerned. The history of the various issues and rearrangements of shares need not be recapitulated here; suffice it to say that there are 179,026 preference shares of £1 each and 453,132 ordinary shares of 16s. each. The preference shares take all the profits until they have received 100%; when this has been paid they take a cumulative preferential dividend of 20% and subsequently rank equally with the ordinary in the distribution of further profits. The first dividend was paid in September last, and for the year 1909 the holders of preference shares received 25%. During 1909, 227,502 tons of tailing was treated, averaging 20.38% zinc, 5.8 lead, and 8.82 oz. silver. For the first six months the supply came entirely from the Block 10 dump, and later other material from the British Broken Hill dump was added in a suitable proportion as determined in the experimental plant. The company does not give the figures showing the amount of concentrate produced by the Elmore plant, but states that the average assay value was 43.48% zinc, 10.83% lead, and 16.43 oz. silver. On the removal of the gangue by the Elmore process the concentrate is sent to Wilfley tables in order to effect a further separation of the sulphides, with the special object of reducing the lead content. The final production was 84,698 tons of zinc concentrate averaging 46% zinc, 7.3% lead, and 15.08 oz. silver, together with 6411 tons of lead concentrate averaging 57% lead, 16.3% zinc, and 38½ oz. silver per ton. When the Wilfleys were erected it was supposed that twenty would be sufficient to handle the product from the Elmore plant, but as the capacity of the latter was continually increasing it was found necessary to double the installation of Wilfleys. When the Wilfleys were overtaxed the separation of lead was not done efficiently, with the consequence that the zinc content in the zinc concentrate was not raised as high as it should be. Since the new Wilfleys have been provided the zinc concentrate has been raised once more to the more profitable grade of 47%. The zinc and lead concentrates produced during the year sold for £276,946. The treatment cost, including royalty, was £96,522, and £56,946 was charged toward the cost of purchase. In addition £21,043 was allowed for depreciation, and after paying expenses of administration, a profit of £100,867 was left. The year started with an adverse balance of £59,650, of which £29,650 was written off when the ordinary shares were reduced from £1 to 16s. and the remaining £30,000 has liquidated out of the past year's profit. As already mentioned, £44,756 has been paid as dividend and £21,111 has been carried forward.

The Sulitjelma copper mines are in the north of Norway within the Arctic circle, and were first discovered 25 years ago. They are worked by a Swedish company of which N. Persson, of Helsingborg, is the main spirit. Though so far away, the business is an important one, employing 1600 men altogether, and the managers follow metallurgical progress pretty closely. For instance, the Knudsen pyrite smelting process was invented there and is used on some of the ore. The loss of copper in the jigs and tables is large owing to the friable nature of the ore, and quite 40% was lost in the concentration plant. The flotation process was therefore tried experimentally, and as good results were obtained, a single unit, capable of treating 40 tons per day, was ordered. Subsequently in February, 1909, eleven more units were started. These have been working continuously for over a year with excellent results. The tailing from the tables averages 0.8 to 1.4% copper and the concentrate obtained in the Elmore plant runs from 6 to 8½%; the average assay of the final residue is 0.15 to 0.3%, and the extraction is over 80%. The amount of oil used is 2.7 lb. per ton and curiously enough no acid is found necessary. The capacity of the plant is 500 tons per day, but it will work at a much higher rate. The plant requires little supervision, three men per shift and a general foreman being all that is necessary; in fact a plant double the size would not require any more labor. By means of this plant from 800 to 1000 tons of metallic copper per annum is recovered from material that was formerly dumped into a lake.

TORONTO, CANADA

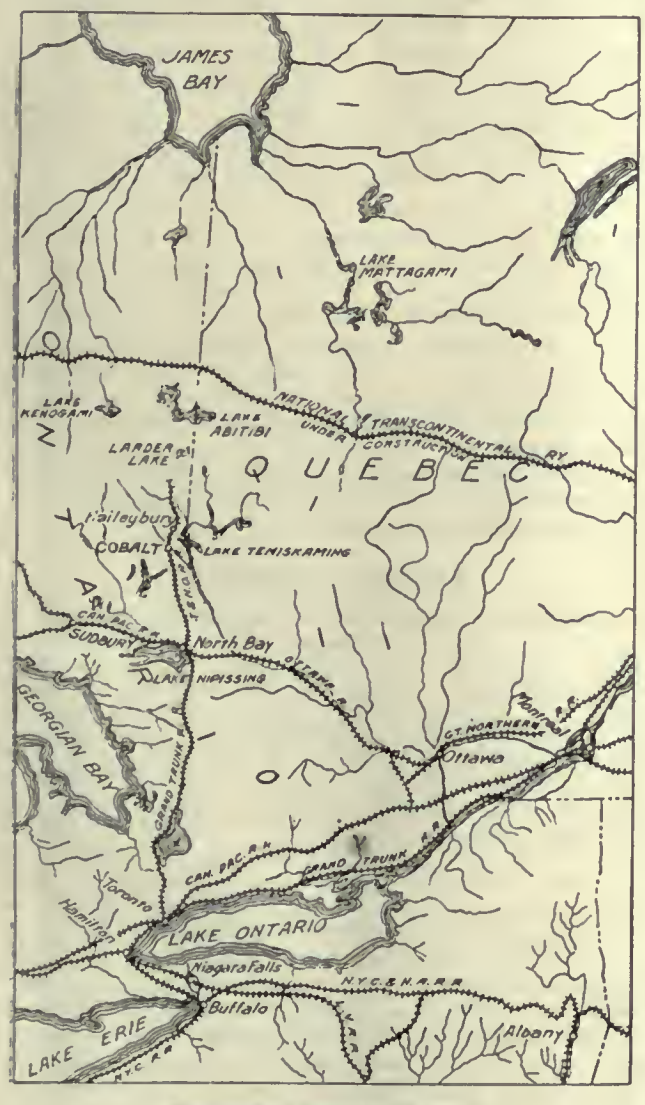
Porcupine Sampling.—Cobalt Prices and Developments. — Canadian Northern and Coalfields. — Iron and Steel Bounties Lapse.—Lake Abitibi Explorations.

As interest in Cobalt declines with a dull and sagging market, Porcupine attracts more attention. The canoe route is now open, and holders of locations are putting large forces of men at work, and many prospectors and mining men are going into the district. The camp has received a decided boost from the results of an assay made by Ledoux & Co. of a consignment of 27 tons from the Hollinger claims, owned by the Timmins and McMartin interests. The shipment consisted of samples of each shooting down to the 60-ft. level, where cross-cuts were made in two shafts 350 ft. apart. The selection was carefully made by competent engineers. The ore assayed $202.75 per ton.

An outbreak of smallpox in Cobalt followed by a rigid quarantine, and the general weakness in the stock market generally, is quite sufficient to account for the depression in Cobalt shares. No material revival is likely to take place until fall. A number of discoveries have recently been reported, but any slight advance in price ensuing is always the signal for a rush of profit-takers, which soon forces the price down to about the former level. The Rochester has opened up some high-grade ore on the 50 and 75-ft. levels, the vein at the latter depth being 6 in. wide. The La Rose has encountered an ore-shoot in No. 3 vein on the 75-ft. level, where the vein is 43 in. wide and carries 4000 oz. silver per ton. On the east side of the Hill shaft an orebody is being stoped for 145 ft., the vein carrying rich ore from the bottom of the open-cut to the 135-ft. level. No. 4 vein has been found to grow stronger with depth running 3800 oz. silver per ton. Driving on the 88-ft. level of vein No. 2 of the Lawson property indicates a good orebody between this level and the surface. When the mill of the Nova Scotia is operated the ore will be treated by amalgamation and cyanidation. Concentrating tables will not be used. The Silver Cliff mill is running on lean ore. The higher grades are not to be touched until the process has been more thoroughly tested. Raises are being put through from the winze to the adit-level a distance of 62 ft. and 270 ft. apart. Good milling ore exists all the way and the mine will have an orebody blocked out 270 ft. long and 62 ft. high, of 4-ft. milling rock with some high grade. Kerr Lake will soon be operated by Montreal River power and No. 9 shaft now at the 100-ft. level will be opened up on an extensive scale. Driving on No. 7 vein at the 200-ft. level shows the vein as rich as ever, running from 20 to 30 in. wide for the last 40 ft. and yielding ore carrying 4500 oz. per ton. No. 3 shaft is being worked at 400 ft. and drifts north and south show rich ore. The new plant of the Bailey is in operation and the shaft is being put down from 100 ft. to a depth of 265 ft. Several feet of good milling ore have been proved. The Trethewey in driving an exploratory cross-cut north from No. 2 shaft at the first level recently cut a new vein 4 in.

wide containing 6000 oz. per ton, the wall rock also showing leaf silver.

The Canadian railroad companies have lately shown great energy in securing the control of Western coal deposits. Two important acquisitions have recently been made by the Canadian Northern interests. A company entitled the Canadian Collieries (Dunsmuir), Ltd., capitalized at $20,000,000, controlled by the Canadian Northern, has secured for a figure stated at $11,000,000 the Dunsmuir collieries and coal lands on Vancouver Island. D. D. Mann, vice-president of the Canadian Northern, has announced that the line will be extended west from Edmonton or that neighborhood, to the Brazeau coalfields in the foothills of the Rocky Mountains, the company having acquired a charter covering this route from the Alberta Midland railway. The coal area is about 10,000 acres in extent and yields a high-grade bituminous coal, and will cost about $10,000,000. British and German capitalists are associated in the deal with the Canadian Northern. The opening of the Brazeau coalfield will place



Map Showing Portion of Ontario.

the railroad in an independent position as regards the coal supply for their Western lines, and it is also expected that with the settlement of the region and the development of industrial centres there will be a steady market for their output.

In accordance with a recent announcement of W. S. Fielding, Canadian Finance Minister, the iron and steel bounties paid for some years by the Government have been with one exception allowed to terminate with the present year. The bounty on wire rods, however, will continue for six months longer, ending June 30, 1911. Mr. Fielding stated to Parliament that he expected that the iron and steel interests would press for an increased duty by way of compensation, but intimated that it was as yet too early to forecast the action of the Government in that respect. There is likely during the coming summer to be considerable activity in the exploration of the northern portion of Ontario with a view to discovering further deposits of valuable mineral. The Provincial Department of Mines is sending out several exploring parties in the course of the next few days. J. B. Tyrrell, of the Canadian Geological Survey, has already left for Fort Matachewan to investigate reported gold discoveries in that region where a considerable amount of snow-shoe prospecting was done during the winter. Prospectors are now going in large numbers into the lower Lake Abitibi region where placer gold is stated to occur, and several outfits are now at work on the lake shore. Molybdenite discoveries are reported at Twinback lake in the eastern Abitibi district near the Grand Trunk Pacific line. It is stated that the veins carry 400 lb. molybdenite per ton, with traces of gold, and outcroppings of the same mineral in smaller quantities have been found in other parts of the district.

TINTIC, UTAH

Lower Mammoth at Deep Levels. — Gemini Orebodies. — Knight Group.

The Lower Mammoth M. Co., of which John Dern, of Salt Lake, is president, is shipping four to five cars of ore per week, returns for which are about $20 per ton. The bulk of this is taken from the stopes between the 1700 and 1800-ft. levels. It consists of lead and silver in a quartz-lime gangue, the lead occurring as carbonate and the silver as chloride, ruby, and native. There have been some shipments of copper ore, which is found in certain veins clearly segregated from the lead ore. The principal vein, as shown by the open stopes between the 1700 and 1800-ft. levels, is 15 to 20 ft. wide, and it contains there practically no waste. The oxidized ore extends to and probably below the 1800-ft. level. Sulphide ore, consisting of galena, iron, and copper pyrite, comes in at 2000 ft., as was demonstrated by a 165-ft. drift south on the vein at this level. The major vein on the Lower Mammoth is the same as that of the Mammoth. Both those mines are on a north-south mineral zone, whose orebodies follow closely a brecciated dike in the limestone. The original workings in the Lower Mammoth were opened through the old shaft sunk from the surface. Later, a 700-ft. adit was driven, at the farther end of which a roomy station was cut, and a 2-compartment shaft was sunk from this station to 1200-ft. depth. Beginning December 14, 1908, the work of enlarging the shaft to accommodate three compartments was accomplished by March 27, 1909, which comprised putting in timbers, ladder-way, air-pipes, and the equipping of two compartments for hoisting. The total cost was $11.75 per foot. That work was followed by sinking three compartments from the 1200-ft. station to the 2000-ft., the cost of sinking and equipping from 1200 to 1900 ft. was $23.75 per foot, the last 100 ft., from 1900 to 2000, being $28.75 per foot. This performance was under the direction of E. C. Coffin, who has held the position of superintendent during the last three years. Near the collar of the shaft, at the interior station, is a double-drum electric hoist, operated by a 165-hp. electric motor. A force of 50 men is employed. Some ore is being mined and shipped from the 1000-ft. level by lessees.

The Gemini mine, which has been operated continuously during the last twenty years, has yielded $2,000,000 in dividends. During the greater part of this period it was owned principally by the late J. Q. Packard, and it is now a part of his estate. Jackson C. and John H. McChrystal are now, and for years have been, manager and superintendent, respectively. The Gemini holdings are on one of the great north and south mineral zones of the Tintic district, occupying a position on the northern section of the zone. Extending south from the Gemini, on the same belt, are the Bullion-Beck, Eureka Hill, Centennial-Eureka, and Opex workings. Three parallel fissures have been opened in the Gemini, and these are cut transversely by a number of cross-fissures, making a rather complex system of orebodies. The main fissures have a dip east, the cross veins dip south, the pitch of the ore-shoots being north. The width of the zone, measuring from the west fissure to the east fissure, is about 450 ft. The workings are entered through a 1600-ft.

shaft, and by means of a winze that was sunk 300 ft. from the 1600-ft. level. An electric hoist is operated in the winze between the 1600 and 1700-ft. levels, the latter being the water-level at present. The ore on the middle vein was first opened on the 700-ft. and on the west vein at the 1400-ft. level, the shoots on the latter having been followed down to the 1700. The oxidized ore is found as deep as the 1600-ft. level, but below this most of the ore is sulphide, carrying galena, sulphide of silver, and some copper. A high-power electric pump has been installed at the 1600-ft. station, and the lowering of the water from its present level at 1700 ft. to 1900 ft. may be undertaken soon. In this work other companies may participate; the Centennial-Eureka company is installing a pumping plant at the same water-level in its mine, and it is reported that the Chief Con. may do similar work later on. The Ridge and Valley mine, adjoining the Gemini on the north, is being operated through the workings of the latter, and from it three cars of ore per week are being shipped, running 25 oz. silver and 35% lead.

The Knight group of mines, comprising the Colorado, Beck Tunnel, and Iron Blossom, is situated on the east side of the Tintic range, and part of it covers the eastern limit of the limestone area, and extends to the adjacent porphyry. The three mines of the group are producing and shipping ore. Development on the Iron Blossom is the newest and most interesting. While the main north and south vein here is in limestone, it is within a few hundred feet of the contact of the latter with porphyry. This vein has been opened by levels 400 and 500, which were driven from No. 3 shaft. On the 400-ft. level a drift was run 700 ft. on the vein, showing solid ore 40 to 70 ft. wide. A 50-ft. winze in ore from this level served as the centre from which a chamber 50 ft. high and 8 sets wide was stoped out, resulting in a large tonnage of ore running high in carbonate of lead and chloride of silver. A drift on the vein has been made on the 500-ft. level, a 50-ft. cross-cut on the vein not having exposed either wall. A raise has been made from the 500 to the 400-ft. level, and now all ore stoped between the two levels will be taken out from the 500-ft. station. No. 1 shaft, also on the Iron Blossom, which has reached a depth of 1550 ft., is 3500 ft. southeast from No. 3, and the two are to be connected by drifts which are being run on the vein from both shafts. Most of this work thus far is in ore. Sinking is still in progress in No. 3 shaft, and it is to continue till a depth of 200 ft. is reached. All the shafts of the Knight mines are equipped with electric hoists. Shipments amount to 80 tons of ore per day from Iron Blossom No. 3 shaft, 75 tons from No. 1; four cars per day from the Colorado, and occasional shipments from the Beck Tunnel. The Knight railroad, that extends from Silver City to his own mines on the east side of the range, likewise serves other mines in that part of the district. Charles Zabriskie is superintendent of the Iron Blossom group, and Harvey Ross foreman.

BUTTE, MONTANA

Butte & Superior. — Alex Scott. — Zinc Mining. — Wickes and Radersburg.—Davis-Daly.—East Butte.

The Butte & Superior company will in the next few weeks be treating 500 tons of ore per day at the Basin concentrator. The company has secured a lease on one-half of the concentrator. Machinery has been ordered and will be installed at once. The Butte & Superior's half of the plant will be operated by three shifts of men. Structural steel has arrived and the work of preparing the foundation is being rushed. It is estimated that at the present rate of progress the shaft in the Alex Scott will be down 1600 ft. by June 1, at which depth a station will be cut and an electric pump installed. A cross-cut will be run to intersect all of the veins, and the work of getting ready for shipping ore will be vigorously pushed. From the 500-ft. level to the 1400-ft., a number of veins containing copper and silver in commercial quantities have been opened. On the 1400-ft. level the main vein has been opened and an ore-body more than 20 ft. in width developed. The ore carries considerable bornite and copper glance.

The work of exploring the old Emma mine for zinc ore in paying quantities has been abandoned and the hoist is being dismantled. James Wilcox, formerly superintendent of the Mass Consolidated and now president of the Calumet-Corbin company, has been in Butte. He had been inspecting the company's property, which consists of seven claims in the Wickes district and seven in the Radersburg district, the latter property being known as the Mammoth mine. Mr. Wilcox is very enthusiastic over the Radersburg property. He considers the district the most important gold camp Montana has ever had, on account of the value of the sulphides increasing and the width of the orebodies increasing in depth. He reports the Keating to be down 600 ft. and showing well in gold and copper. The ore at the 500-ft. level of the Black Friday assays $300 per ton in gold. The Ohio Keating is down 300 ft. and a good body of ore has been found. The Ohio Keating is installing an electric hoist. The Mammoth is installing a gasoline hoist and soon will be hoisting ore. At the 50-ft. level an assay shows $8 in gold, 50 oz. in silver, and 63.2% lead per ton. The men associated with Mr. Wilcox in the Calumet-Corbin are residents of Minneapolis and Boston. The work in the Davis-Daly mine is going along as usual, except that the force of miners employed is reduced to 25 owing to the fact that no arrangements have yet been made for the shipment of ore. Cross-cutting is now proceeding on the 1700-ft. level to the vein. Miners who are at work say that large bodies of ore have been blocked. It is announced that Mr. Heinze will arrange for the treatment of his ore either by building a spur from the Colorado to the Great Northern railway or by arrangement with the Pittsmont smelter owners. H. E. Gross, president of the East Butte Copper M. Co., has returned to Boston after making an examination of the mines and smelter of the company. While here he arranged with the Butte-Ballaklava company for treatment. In order to do this another furnace will have to be started in the Pittsmont smelter, and arrangements are progressing toward this end now. A certain amount of custom ore will be treated in addition to the 400 tons per day it is expected that the Butte-Ballaklava will ship.

BRITISH COLUMBIA

Phoenix Items.—Trail Smelter Production.— Nelson and Slocan Outputs.

The Greenwood Miners' Union has called off the strike against the British Columbia Copper Co. and the company announces that it will immediately resume operations. The Granby company is working a diamond-drill on its Gilt Edge property. The ore shipments from the Boundary district for the week ended May 14 and for the year to that date were as follows:

	Week, tons.	Year, tons.
Granby mines	22,509	473,038
Snowshoe	2,500	80,420

At Rossland, the Centre Star, Le Roi No. 2, Ltd., Le Roi, Mayflower, and I. X. L. mines are working steadily, and now the Nickel Plate has been leased by a local syndicate and during the past week shipped 90 tons of select ore. The metallic production at the Trail smelter during the month of March was as follows: gold, 12,487 oz., $254,507; silver, 178,542 oz., $92,368; copper, 468,565 lb., $62,267; lead, 3,766,388 lb., $106,565; making a total value of $515,798. The value of the metallic production for the nine months prior to March 31, was $4,367,420. These figures indicate that the production for the twelve months will exceed those of the previous twelve. The ore shipments from Rossland for the week ended May 14 and for the year to that date were as follows:

	Week, tons.	Year, tons.
Centre Star group	3,110	72,564
Le Roi No. 2, Ltd	390	11,263
Le Roi mine	300	5,294
Nickel Plate	90	90

At Nelson the Consolidated M. & S. Co. of Canada has resumed work on the Queen Victoria property. There is a

large showing of low-grade copper-gold ore on the claim, and it is the intention to make steady shipments to the smelter at Trail. The company is doing a lot of diamond-drill work on the Sullivan group, which it is working under a lease and bond. A good strike is reported from the Cliffman property, Toad mountain, back of Nelson. Three feet of gold-bearing ore has been opened up that will assay from $15 to $25 per ton. The following table shows the quantity of ore received from local silver-lead mines during April and the lead content:

	Net weight, lb.	Lead content, lb.
Blue Bell (conc.)	393,178	246,026
Monte Cristo	7,178	2,598
Rambler-Cariboo	125,662	53,318
Richmond-Eureka	707,351	107,726
St. Eugene (conc.)	3,297,835	1,966,772
Standard	133,548	76,248
Sullivan	2,616,384	511,515
Yankee Girl	468,164	20,453
Van Roi	241,080	152,036
Total	7,990,380	3,136,692

The ore and concentrate shipments from the Slocan-Kootenay mining district for the week ended May 14 and for the year to that date were as follows:

Rambler-Cariboo	21	378
Richmond-Eureka	29	1,719
St. Eugene (conc.)	368	7,007
Silver Cup (Ferguson)	60	527
Sullivan	129	4,030
Van Roi (conc.)	122	309
Yankee Girl	128	2,391

NEW YORK

San Cayetano and Other Mexican Issues. — Copper Surplus and Production. — Clark and Butte. — Porphyry Reserves and Values.—Granby.—Union Copper.—Heinze Stocks.—Braden Copper.—Canadian Mines.

The San Cayetano Mines, Ltd., which, about two years ago passed to the control of the Lewisohn interests, is about to be offered to the public. The property is in Guanajuato, Mexico, and the present move marks the entry of the Lewisohns into Guanajuato. In view of the fact that two or three of the biggest producers in Cobalt are controlled by the same people, the move is especially significant. It shows a faith in the future of silver, which warrants the development of immense orebodies of low grade, as contrasted with Cobalt. That the Lewisohns already owning or controlling the Kerr Lake, a leader in the Cobalt dividend list, and the Wettlaufer of South Lorrain, which is held to be a sure profit earner later, should definitely commit themselves to Guanajuato is distinctly a matter for congratulation among Mexican silver producers. San Cayetano has a capital of $250,000, par $5. This is to be increased to $1,500,000 and such shares as are not taken by the stockholders of the General Development Co. and the Silver Mines Exploration Co., both holding companies controlled by Adolph Lewisohn and his friends, will be later offered to the public. The Guanajuato Power & Electric Co. has purchased the Electric Light & Power plant at San Luis Potosí, through its subsidiary the Central Mexico Power Co. The Guanajuato Power & Electric Co. is growing rapidly. It owns hydro-electric plants, one on the Duero and one on the Angulo river. In addition to the mines and the city of Guanajuato, it supplies power to Leon, Irapuato, Celaya, Salamanca, La Barca, Aguascalientes, and is now building into Zacatecas. The report of Russell T. Cornell, who has been examining the properties of the Pacific Mining & Smelting Co., for the General Development Co., has been received.

The copper agencies are once more pointing to the fact that the entire copper surplus and stocks on hand represent only enough metal to meet requirements for from two to four months and that in reality such amount is not excessive. The argument is good were it not for the fact that there are many producers continuing to output copper at little or no profit rather than face the heavier losses of shut down or drastic curtailment. Utah Copper and Nevada Consolidated are barely meeting dividend requirements, reduction of dividend means stock market shrinkage, reduction of output means interest and depreciation charges increasing and dividend reduction as well. In the meantime the deep level mines cannot be philanthropic, there are more steam shovel coppers in the making, and so the situation, in a way, aggravates itself and all connected with it, save the consumer, who refuses to be stampeded into filling up the stock yard. The most encouraging feature in the metal market is the report of sales by the larger agencies aggregating upward of 100,000,000 lb. Such sales will make the next month's report of production much more favorable. The elimination of W. A. Clark as a copper producer and smelter at Butte, leaves Anaconda in undisputed possession of almost the whole of Butte, and when the Amalgamated shall have transferred the newly acquired properties in due course, the new Anaconda will have a potential copper output of 325,000,000 lb. Tuolumne, East Butte, East Butte Extension, Butte-Ballaklava, and Davis-Daly are the most important mines outside of the merger. North Butte remains off the reservation, but its position is something of a mystery. Mr. Clark sailed for Europe as soon as the deal with the Amalgamated was concluded, announcing in a final interview, however, that he had no intention of retiring from the copper field. New properties have developed near his Arizona mine and it will be no surprise to note the enlargement of the United Verde and the absorption of some of the prospects adjoining it, which bid fair to develop into mines. The ten thousand shares of North Butte recently issued in exchange for the outstanding interests in the Croesus claim have been listed on the Boston Stock Exchange.

A recent report on the ground of the Chino Copper Co. credits the property with ore reserves, as of May 1, of 17,948,566 tons, averaging 2.6% copper. Some recent calculations made show the tremendous figures into which the prophyries run. Utah is figured to have 150,000,000 tons of ore in sight which on a 13c. copper market, is estimated to have a net value of $1.20 per ton giving Utah a net valuation of $180,000,000, or, a book value, so to speak, of $117 per share on its issued capital of $1,540,000, against a market value of $42 to $46. Nevada Con. is estimated to have ore in sight of 32,000,000 tons, of a net value of $1.65 per ton, giving this property a net value of $52,800,000 or $26 per share against a market price of $18. Ray Con. with a capital of 1,200,000 shares including the 200,000 shares to be exchanged for Gila, has an estimated tonnage of 67,000,000 tons, of a net value of $1.25, net value of the property $83,700,000 or a figure of $70 per share against a market price of $17. While these figures make a most imposing showing for the porphyries, the fact remains that Nevada Con. and Utah are only meeting dividend requirements on the present market and at present prices Utah returns about 7½% on the investment, while Nevada pays 8⅛% at $1.50 per annum on a market of $18. Since mining dividends must mean return of both principal and interest, whether the property be one of short or long life, the deduction is unavoidable that, in spite of the showing made, as to the values to be handled before the properties shall have been exhausted, the two principal porphyries, which have reached the stage of production are selling too high.

J. P. Graves, vice-president and general manager of the Granby, is in New York and is preparing a complete detailed report on the Granby property, to be submitted to the directors in a few days, and later, to the stockholders. The examination upon which the report is based was a very minute one, and the forthcoming document is expected to throw much light on prevailing conditions; in fact, to show the Granby shareholders just where they stand. The report will also be of much interest to the public at large as an aid in analyzing the future of some of the other low-grade milling coppers. A pool is being formed in Union Copper Mines. Union Copper of North Carolina has been the vehicle or the medium for almost every kind of market tactics known. This most recent move in the issue is a

request to the shareholders to place their stock in bank, under option to an alleged English syndicate supposed to be seeking control of the property. As the option is to run until November 1, 1910, the interim may be profitably employed in carrying out a few market manipulations, rendered wholly safe by having the outstanding stock locked up in the safety vault. The acquittal of F. Augustus Heinze was expected to be the signal for a few stock market pyrotechnics in Ohio, United Copper, Stewart Mining, and Davis-Daly, issues in which the Heinze interest is supposed to predominate. United Copper made an advance on a small sale, but otherwise the Heinze specialties were quiet. The request made to the United shareholders a few days ago by the Western Development Co., a concern which succeeded the defunct firm of Otto Heinze & Co., for agreements to exchange their preferred stock for Anaconda, has been followed by a letter from the same concern agreeing to exchange, on or before July 31, 1910, one share of Anaconda for each share of United Copper preferred the recipient might purchase in the open market, in good faith, within ten days from the date of the letter. All of the officials of the Anaconda deny guilty knowledge, and while the Western Development Co. officers declare the proposition was made in good faith and was not a stock jobbing scheme, they explain, at the same time, that as the public holds but very little of the preferred issue of United Copper, any widespread buying movement that might be incited would push the price above that of Anaconda. There has been no advance in United, and it is evident that the ruse failed to work.

Pope Yeatman has returned from the Braden Copper mines in Chile, where he has been engaged in an exhaustive examination. There is now under construction on the ground a smelter and a concentrating plant, to have a capacity of 2000 tons per day; ore reserves, as developed in the two orebodies now being opened, are estimated at 7,000,000 tons, averaging 2.7% copper. Mr. Yeatman figures costs at 7 to 7½c. per pound when the plant is completed, and a further saving of ½ to 1c. per pound is thought possible by the adoption of a leaching process for the concentrate in connection with electrolytic precipitation. An experimental leaching plant is being built. The annual report of the Tonopah Extension shows a deficit of $40,405 for the year ended March 31. Generally speaking, the improvement shown in the Tonopah has been one of the bright spots in the mining market and the great interest shown is indicative of the welcome which would be given any general revival of activity in the Nevada camps. The Eastern public prefers any of the Goldfield prospects, if at all active, to a Cobalt dividend payer. Such preference is almost purely a matter of sentiment, but nevertheless as strong a market factor as if based on the most careful analysis of mine values. The Standard Consolidated of Bodie, California, an old time producer, has been admitted to trading privileges on the New York Curb. Cobalt Central, which has been something of a stock market performer, much advertised, and the shares widely scattered, is said to be going into the hands of a receiver, following the recent failure to place a $400,000 bond issue. The report of such action cannot at the moment be verified, but a reorganization is a certainty. There is good progress being made at Porcupine. The surface showings are so big that in all cases judgment is withheld awaiting exploration at greater depth. Veins 5 ft. wide, stripped for a length of 400 ft., with a pay-streak in the centre 2 ft. wide, and showing free gold in practically all of this length, seem out of all reason. It is to the credit of the operators at Porcupine that no runaway boom market has been attempted. Options on prospects are held at prohibitive figures, but there has been no attempt at wholesale promotions. On the ground of the Porcupine Gold Mines Co. sinking is progressing on the vein above described, with a view to running a drift under the outcrop and proving its value at a depth of 75 to 100 ft. The road problem is troublesome. The Timmins people, working the Hollinger group, are ready to make another shipment of ore as soon as a wagon-road can be completed from Porcupine to the railroad. On this property, as well as on the 'Home Claim', which is operated by people interested in International Nickel, sinking is in progress, and as free gold continues to be found wherever development is in progress, the outlook for the moment is exceedingly bright; so bright, in fact, that the general attitude is a waiting one.

JOHANNESBURG, TRANSVAAL

Administrative Changes.—Marriot System.—Faulty Shafts.

Very important changes in the technical administration and some of the most important mining and financial houses operating in the Transvaal are taking place. Mr. Leslie Simson has resigned his position as superintending engineer of the Consolidated Gold Fields of South Africa and his place has been taken by C. D. Leslie, who has managed the Simmer & Jack and Robinson Deep mines. T. W. Craig, who has been in charge of the Knights Deep and Simmer East properties at Germiston, has been appointed assistant superintending engineer. Although no definite announcements have yet been made, it has been an open secret for some time past that changes were pending in the engineering staff of H. Eckstein & Co. and the Johannesburg Consolidated Investment Co. (otherwise Barnato Brothers). It is anticipated that some definite statement will be communicated at an early date. In the meantime it is premature to discuss this subject at any length. H. F. Marriott, who is chief technical adviser to the firm of Wernher, Beit & Co., has endeavored to introduce a new system of accounting mining returns on the Rand. In so far as the mines of the Eckstein group are concerned, it was stated that the new method would be carried into effect immediately and that instead of monthly returns being issued as heretofore quarterly reports would be prepared on the new basis. The idea underlying the scheme was of course to encourage cleaner mining and to induce managers to pay less heed to low working costs and to give more attention to high profits. The general opinion among mining engineers here seems to be that by closer supervision the aims and objects of Mr. Marriott's system can be attained without resorting to such a radical departure as is entailed in the square fathom method. The general opinion seems to be that the 'Marriott method' is open to just as many abuses as was the old, that the new system will greatly increase the labors of mine staffs, and that a large amount of statistical data will be published which the average shareholder will entirely fail to understand, and that the publication of quarterly instead of monthly statements will tend toward diminished confidence in the industry on the part of European investors.

Two or three shafts in the central section of the Witwatersrand goldfields have of late proved defective, and although it cannot be said that there is at the present day any cause for undue anxiety regarding these shafts they will have to be carefully watched. At the Ferriera Deep the No. 2 shaft has given trouble for months past, and the company's tonnage and profit earnings have suffered in consequence. Quite recently the shaft was repaired, but a few days ago further 'creeping' took place and a few of the timbers gave way. Hoisting was then suspended for some time and the shaft is now in proper working order again. At the Robinson Central Deep shaft of the Crown Mines hoisting has been interrupted lately through the breaking away of a skip in the shaft and the tearing up of a good deal of rail and timber. This, too, has been remedied. There can be no denial of the fact that in some of the mines on the Rand—especially those in the more central section of the fields—the state of the underground workings is not satisfactory. This condition of affairs is to a large extent a legacy of the faulty mining methods of the earlier days, and it cannot be said that the present policy of accelerated production and the raising of a maximum tonnage each month irrespective of some other important considerations tends to improve matters. Sand filling should do much toward bettering the state of underground workings. All the mines of the Central Rand are adopting sand filling on a large scale, so large in fact that it is predicted that within five years all or practically all of the unsightly dump heaps which now cover the central portion of the main reef fields will have disappeared.

General Mining News

ARIZONA

COCHISE COUNTY

At the Bisbee Extension three shifts are working on the 400 and 700-ft. levels. Considerable difficulty is being experienced with the heavy flow of water and the hoist has been kept busy bailing when not hoisting ore or waste. Another boiler and pump is at Lewis Springs, seven miles from the property, and will be installed in a short time.——At the Junction shaft of the Superior & Pittsburg, development is centered on the 1500-ft. level where the orebody has been opened to a width of 65 ft. It is reported that the company is now planning to install a large compressor-plant at this shaft that will act as a central air distributing point.

GILA COUNTY

(Special Correspondence).—An option on the property of the Globe Mining Co., consisting of 338 acres of mineral land, best known as Mineral Farm, and situated three miles northwest of Globe, was given to W. A. Canode as representative of Chicago capital, at a stockholder's meeting held in Globe May 19. The purchase price named is $500,000, which is to be paid in cash installments distributed over a period of five years. The first and second payments of $5000 each fall due August 1 and January 1, respectively, and October 1, 1911, has been set as the date of the third payment of $35,000. It is provided that the holders of the option shall begin development work by January 1, 1911, and that within one year from that date, at least $100,000 must be expended in operations. The present workings on the property consist chiefly of a shaft 415 ft. deep, with about 100 ft. of cross-cutting completed on the fourth level and of an adit several hundred feet long. It is further provided that a royalty, amounting to 5% of the proceeds from any ore mined and shipped by the purchasers before making the final payment, shall be paid to the Globe Mining Co.——Of two churn-drill holes being put down on the Colorado claim of the Inspiration property, one has struck chalcocite ore of good grade at a depth of 500 ft., and the other is still passing through the capping.——The National Mining Exploration Company has discontinued work on the 660-ft. level temporarily at the Williams shaft and has resumed shaft sinking with a view to establishing a level at a depth of 778 ft.——The Warrior Development Co. has recently increased its shipments of 10% ore from 90 to over 100 tons per day.——Two 40-hp. hoists are expected to reach the Copper Reef Consolidated mines by June 1.

Globe, May 21.

MOHAVE COUNTY

The Gold Hills Mining Company has let a contract to sink a shaft 200 ft. on its property in Weaver district. These mines were recently taken over by the company from Barney McCall and are considered among the best properties in that portion of the country.——It is reported that a new company is to take over and operate the old Lone Star mine, near Mineral park. The mine at one time was one of the richest producers of ore in the county, but after the surface ores were worked out little was done with the property on account of the difficulty in handling the water.——On the Last Chance mine, in the Wallapai Springs district, W. E. Frost, O. D. M. Gaddis, Walter Meyers, and Harry Mehaffy have a fine showing of gold ore.——In cutting the station at the 150-ft. level of the Keystone mine the S. R. Porter Mining Co. opened a 2-ft. vein. The ore is said to be of a high grade and something similar to the cross vein from which a large part of the rich ore produced by the mine was taken in early days.

YAVAPAI COUNTY

The United Verde Copper Co. is now using the tailing from the Henrietta mill in the Big Bug district for converter lining. It is estimated that there is an accumulation of approximately 20,000 tons of this material which is very silicious and will assay between $4 and $6 per ton.——The shaft at the Monte Carlo mine has been retimbered and a 10-ton mill is being installed.——The Big Bug Placer Mining Co. has made the final payment on the T. F. Averill placer claims at Mayer and will build a dredge on the ground.——It is reported that a rich vein of silver ore has been opened in the May Day mine in the Bradshaw mountains.——A 6-ft. Huntington mill is being installed at the Big Pine group in the Hassayampa district.

CALIFORNIA

CALAVERAS COUNTY

At the Good Hope mine, near West Point, there are about 50 tons of milling ore on the dump and 10 tons of high-grade that will be shipped to the smelter.——Louis Lloyd cleaned up $1000 from the milling of 10 tons of ore.——Arthur French is now working the Austrian mine which he purchased recently.——There are 15 tons of milling and 5 tons of smelting ore on the dump of the Great Bend property that will soon be treated.——Sterling & Wickman are running their cyanide plant in Mott's gulch treating the old tailing that has accumulated from the mills.

INYO COUNTY

A new shoot of silver-lead ore has been opened in the Monster mine at Big Pine, in the White mountains, and shipping will be resumed. The severity of the winters and the remoteness of the district has prevented the Monster from becoming a regular shipper as it now promises to do.

NEVADA COUNTY

(Special Correspondence).—Work on the new cyanide plant at the Empire mine is progressing rapidly.——Good ore has been cut near the shaft in the Union Hill where the company is developing on two veins.——The Central Consolidated is extracting ore running $10 to $100 per ton from the middle vein. It lies between slate and porphyry and is over three feet wide.——At the Champion mine a large force is at work under the old management and 35 stamps are dropping steadily.——Hugh Craney is arranging for the re-opening of the Oro Grande mine, 15 miles north of Nevada City.——Operations have been resumed at the Kenosha mine with a small force of men and the shaft will be deepened.

Grass Valley, May 23.

At the Cassidy claims in the Grass Valley district where work was resumed a short time ago new machinery has been installed and the vein opened in two places. An average of a number of assays showed the ore to have a value of a little over $10 per ton.——The Prudential Mining Co. has secured an injunction against the Tarr Mining Co. restraining the latter from turning the water from the ditch that supplies the Prudential mill. The water was turned off the early part of the month stopping the work at the Prudential. The two lower levels of the mine filled while the power was cut off and will have to be unwatered before active work can be resumed.——The final payment on the bond on the Native Son mine in the Nevada City district has been made by J. H. Bishop who represents the new owners. Work will be started in the adit now in 180 ft., and continued about 600 ft. to intersect the vein.

SHASTA COUNTY

The Mountain Copper Co. is shipping on an average of four cars of ore per day to its reduction plant at Martinez. This ore is all taken from the Iron Mountain mine as very little is being done at the Hornet.——The Mount Shasta Power Co. is installing a compressor at the tunnel which it is driving at the Big Bend of Pit river and will continue the work with machine-drills. The tunnel will be approximately seven miles long when completed, and carry 25,000 miners' inches of water, obtaining a fall of about 900 ft.——H. O. Cummins has purchased the Kinger, Keswick View, Lucky Smoke, Golden West, Poverty Hill, Big Spring claims, and Golden Eagle mill-site in the Lower Springs district from H. A. Wiser for $15,000.——The Cave Creek Mining Co., which now owns the McClure group, adjoining the Bully Hill, has installed a compressor and let a contract to drive a 500-ft. adit. E. J. McLaggan is in charge of the work.

SIERRA COUNTY

The raise at the South Fork gravel mine, at Forest, cut

through the rim of the channel into the lava and a drift will be started to tap the bottom of the channel.——The gravel at the White Bear mine that has been washed recently has yielded from $5 to $10 per day per man working in the breast.——A 5-stamp mortar and some other mining machinery were hauled from the Downieville foundry a few days ago to the Swastika mine near Sierra City. This equipment is part of the 10-stamp mill that is being erected on the property.——Two shifts are now working in the Sovereign adit in Ladies canyon and good progress is being made.

SISKIYOU COUNTY

Walter Gillis, one of the lessees of the old Summerville mine near Callahan, shipped 98 oz. of bullion which represented the clean-up for a little less than a month. Work for the month previous yielded 109 oz.——The Black Bear mine, which has been idle for several years, is to be reopened by B. F. Daggett.——William Schell, operating near Greenview, on the old channel that parallels the Scott river, has cleaned up all the gravel that was partly worked out by drifting in early days and is now washing new ground. Considerable coarse gold has been found on the bedrock and a good clean-up is expected.

TRINITY COUNTY

Reed & Chapman have installed a Huntington mill on their Windy Camp claim in the Coffee Creek district.——Charles Heath opened a $6000 pocket recently while prospecting in the neighborhood of Minersville.

TUOLUMNE COUNTY

W. T. Forsman, E. R. Argersinger, and Charles Saunders have taken a bond on South Black Oak mine near Soulsbyville for $20,000. The same parties have also secured a bond on the Ralph property between Soulsbyville and Tuolumne on the Cherokee road for $50,000.——The remodeling of the 20-stamp mill at the Dutch mine has been completed and the stamps are now dropping.——The Quail mine, which is a short distance from Coulterville, will be operated this summer. Little work had been done on it for several years until last fall when several cross-cuts were driven from the main adit and some good ore opened.——Robert Fish and Alfred White, working the McGinn lease on the Golden Rule mine, have extracted 60 tons of ore from an old adit on the property and will shortly put it through the mill.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—The new mill for the Mint mine on Covode mountain will be started some time this week.——E. J. Butts, manager of the Big Indian mine on Leavenworth mountain, is preparing to start a new adit, the portal of which will be situated close to the base of the hill. Machinery is to be purchased at an early date. ——G. F. Milliken, of New York, has completed an examination of the Kelly adit workings on Democrat mountain, and it is reported that work will be resumed during the next 30 days.——The Alaska mine at Freeland, owned by V. Jaensen, has been sold to A. Nelson and E. M. Moscript. ——The Ristedt mill on Fall river has been started and will be run on ores from the dumps of the Kinda mine, owned by G. F. Crawford.——Heavy shipments of ore are being made by Jones & Polaro, who are running a number of old stopes in the Franklin workings. Previously the ore was shipped to the Modern smelter, but with the closing down of that plant shipments have been started to the Golden pyritic plant. Returns averaging $340, net, per car on 20-ton shipments have been realized in the past.

Idaho Springs, May 21.

GILPIN COUNTY

(Special Correspondence).—A shipment of five tons of ore made from the Mitchell mine, on Quartz hill, brought a settlement of 1.4 oz. gold, 8.84 oz. silver, and 2.80% copper, or a total value of $28 per ton.——A carload of smelting ore from the Egyptian mine in Nevada district was sent to the Golden smelter the latter part of last week.——Work will soon be resumed on the Next President mine in Gregory district. The property is operated by the Great Bonanza Gold Mining Co.——A carload shipment of smelting ore made last week from the Gilpin King mine brought a settlement at the local sampler of $44 per ton, the copper content being 15%. G. Knutzen is operating under bond and lease.

Central City, May 20.

GUNNISON COUNTY

The new 200-ton mill of the United Colorado Mines Co. is now running and while not operating to its full capacity it is making an excellent saving on the plates and a good concentrate on ore that assays as low as $6 per ton. The company is working about 100 men though the roads are bad and it is almost impossible to haul freight in.——A drift has been run 20 ft. on the ore that was recently opened by the adit at the Dupont property in Crystal basin showing the vein to be about 9 ft. wide.——A gasoline engine and compressor is to be installed at the Hard Cash mine on Galena mountain and work resumed in the adit which is now in 800 ft. There is a large amount of ore opened in the group and the company may erect a small furnace to make copper matte.——Arrangements have been made for the resumption of work at the old Excelsior mine in Baxter basin. The Yankee Blade adit is to be extended through Cascade mountain to tap the shoots of the Excelsior which have yielded large profits from the upper levels.

LAKE COUNTY

Considerable work is planned for the Tennessee Park district this summer and it is probable that several new properties will be in operation in addition to the older ones. The Jennie June, which is the principal producer of the district, will be worked by Al Ganz and associates who have controlled it for the past few years. It is equipped with a first-class plant and would be operated the entire year were it not for the severity of the winters.——The Helen Gould will also be active the coming season and it is probable that a number of shipments will be made as considerable ore was opened last year.——At Leadville, George Cramer and associates have been operating the Waterloo mine on Carbonate hill and shipping ore the entire winter. The ore is a fair grade of galena containing some iron.——Work has been started on the Miller group in Lackawanna gulch on which a good showing of gold ore was made last summer. ——The old adit on the Badger fraction in upper California gulch is being extended and drifts are to be started on the vein that was opened a short time ago.——The old workings of the Colonel Sellers mine are soon to be worked through the shaft at the foot of the hill which was opened a few months ago. Hoisting has been started through this shaft and shipments are being made regularly.

OURAY COUNTY

The Wanakah Mining Co., which recently secured a bond on the American Nettie mill, is overhauling the plant and putting in the foundation for a new compressor that has been ordered from St. Louis. A pipe-line will be laid from the mill to the mine to carry the air that will furnish power for the drills. Machinery for the terminals of the new tram has been shipped and it is expected that it will be in working order early this summer. The company has enough ore blocked out in the mine to keep the mill running for some time and a new adit has been started on the Ironclad lode to develop that portion of the property.——It is reported that the money to carry on the work on the Joker and Genesee groups has been raised in the East and that these properties will be in active operation by the time the Silverton railroad is completed to Red Mountain which should be within a short time.——Machinery for the completion of the Mono-Baltic smelter at Ironton will be shipped as soon as the railroad is opened and work on the plant will be rushed. The building of this smelter will mean much to the Ironton district this coming summer as the Kentucky, Indiana, and a number of other properties will be in a position to operate profitably.——At the Thistledown a large amount of ore has been blocked out in the mine and the mill has been started for the season.

SAN JUAN COUNTY

S. F. Anderson, Ole Erickson, and Ed Anderson have se-

cured a lease on the second level of the Little Maud mine, in the Silverton district, and will commence shipping ore within the next few weeks. Considerable high-grade ore has been taken from the Little Maud property and it is probable that the present operators will erect a mill and cyanide plant if the average of the ore can be kept up to a fair standard.——H. C. Branch, representing the Kuenzel smelter, has been in Silverton recently looking over the field with a view to establishing a plant in Silverton similar to the one at Bella Vista which is reported to be operating successfully on $5 ore.

SAN MIGUEL COUNTY

Alex Righino has secured a lease on a large block of ground in levels No. 5 and 7 in the Smuggler-Union mine at Telluride and is working a force of from 35 to 40 men. The ground is on the old Smuggler and Sheridan locations, and while the lease includes a small piece of virgin ground the most of the work is in re-opening the old stopes that were made in early days when the ore was hauled to Montrose in wagons and forwarded from there to the smelters.

SUMMIT COUNTY

Wineland & Ellwood are crushing the ore from the New York mine which they opened a short time ago in the Johannesburg mill. The ore is free milling and a large portion of the value is saved on the plates.——At the Wellington mine in the Breckenridge district a station is being cut in the adit and a new working shaft is to be sunk. Of the products from the mill only the lead and zinc concentrate is being shipped, the middling being stored for future treatment.——At the O'Reilly work is progressing in a satisfactory manner. The new drills have been placed in the working face and the adit is rapidly being completed.

TELLER COUNTY

A. Osburg, operating a sub-lease in the Victor mine, opened a shoot of ore on the eighth level that assays between $1200 and $1400 per ton, and is sacking it for shipment.——A head-frame has been hauled over to the Fountain Valley claim of the Banner Gold Mining Co. on Rosebud hill, and as soon as it can be erected the machinery installed by the Union Leasing Co. will be started and active mining operations resumed underground. The water has been lowered nearly to the bottom of the shaft, and there will be no hindrance to the operation of the bottom level.——The Republic Gold Mining Co.'s property south of the El Paso is being prospected, but no ore in paying quantities has been found since the present lessees took charge.——The Pinnacle Leasing Co., operating on the Mitchell claim of the Pinnacle company on Bull hill, is breaking ore of a smelting grade 3 ft. wide and making regular shipments. One car shipped a few days ago assayed over $80 per ton, and another containing ore of higher value will be shipped in a few days.——The Maggie property, in the saddle between Bull and Raven hills, is making a production of three cars per week with the ore running from 2½ to 3½ oz. This claim is operated under lease by Carl Johnson, who has opened two distinct shoots. One of the orebodies is 2½ ft. in width, while the other measures a trifle over 3 ft. between walls. The better grade of mineral is coming from the smaller vein under development at a depth of 350 feet.

MISSOURI

JASPER COUNTY

(Special Correspondence).—The low ore prices of the past two weeks has caused the temporary shut-down of a number of the sheet-ground mines in the vicinity of Webb City, Joplin, and Duenweg. Most of these mines have kept the pumps operating that the ground may be well drained when operations are resumed, as it is thought the depression will be of short duration. Other sheet-ground mines have reduced wages or employed men on half time and are storing the ore, where it is possible, and are waiting to sell it until prices rise. The low prices have not affected materially the soft-ground mines, as they can still run at a profit even with ore below the $40 mark.——The John Jackson land at Chitwood, which was bought last fall by a St. Louis company, is being worked now and the A. B. C. mine has been started. The old John Jackson mine was one of the best producers of the district when it was operated several years ago.——Northwest of Joplin in the vicinity of Toms Station a new camp is being formed. For a number of years some mining has been done here, but new prospecting has opened some splendid deposits.——A fine deposit has been opened in the Porto Rico camp on the Knol land, operations being conducted by the Nowata No. 2. The deposit was a pocket at a depth of 100 ft., a type of formation which is common in this camp.——In the eastern end of the county some good shallow discoveries have been made in the vicinity of Reeds and Sarcoxie.

Joplin, May 21.

MONTANA

SILVER BOW COUNTY

(Special Correspondence).—The Pittsmont smelter of the East Butte Copper Mining Co. is now operating two furnaces and handling 250 tons per day of the Butte-Ballaklava ore.——W. A. Clark, who has great faith in the future of the zinc properties in this district, has directed that the Elm Orlu be worked to its full capacity. He has by arrangement with the Amalgamated secured the use of the concentrator at the Butte Reduction Works for the treatment of the ore.——The work of getting the Ophir mine, the property of the Butte Central Copper Co., ready for actual mining operations, is progressing favorably and it will not be long before the work of sinking the shaft to a depth of 1000 ft. will be commenced. An electrically driven air-compressor is to be installed and an electrically driven pump placed at the station on the 500-ft. level.——Just what hitch has occurred in the erection of the Butte & Superior concentrator cannot be ascertained, but all work has been stopped and even the mine surface men have been laid off. The underground work is proceeding as usual and the mine is shipping in the vicinity of 350 tons of ore per day to the Basin concentrator. It is stated that a 7-ft. vein of zinc ore has been cut on the 1600-ft. level that assays 50% zinc per ton. It is pointed out that this ore does not have to be sent to the concentrator, but will be shipped direct to the smelter for treatment and that it will net the company $30 per ton.——Rapid progress is being made with the sinking of the Belmont shaft which is now 1500 ft. from the surface. It will be sunk 500 ft. farther and connections made with the Anaconda 2400-ft. level. This shaft is to be used as an auxiliary to the Anaconda, Never Sweat, and St. Lawrence shafts.——One piece of welcome news which is the direct result of the merger is the announcement that copper is being produced already at 9c. per lb. At all the mines of the Anaconda company development is proceeding and the shipments are up to normal conditions.

Butte, May 23.

It is reported that the Carlisle and Protection claims, situated between the North Butte group and that of the Butte & Superior Mining Co., in the northwestern portion of the Butte district, have been bonded to Pittsburg interests for $400,000. These claims are owned by George Casey, P. J. Brophy, Charles Mattison, Mrs. Martha Fish, W. O. Speer, and others, and have been sought by the companies owning adjoining claims. Little work has been done, but some valuable veins have been proved to the boundaries of these mines.——The Never Sweat mine, one of the Anaconda properties, has resumed operations. It has been closed about two months on account of an accident to the engine, which was wrecked by a runaway.

NEVADA

CHURCHILL COUNTY

A body of ore 4 ft. wide, averaging $117 per ton, two-thirds silver and one-third gold, was cut on the 470-ft. level in the Nevada Hills mine last week.

CLARK COUNTY

(Special Correspondence).—The Ninety-nine Copper Mining Co., opening a mine 20 miles west from Las Vegas, has a contact vein of copper ore between dolomite and blue limestone, which has been partly developed by a 250-ft. shaft and a 70-ft. drift on ore at the 200-ft. level. The ore

consists of copper carbonate, with some tetrahedrite. J. B. Jensen, superintendent, says shipping will be started in June.

Las Vegas, May 20.

ELKO COUNTY

A 40-ton Lane mill is to be installed at the Sleeping Beauty mine in the Gold Circle district and the work of putting the road in shape from Golconda has been started. Two mills, the Rex and the Hartley, have been in continuous operation for some time, and it is thought that the Gold Circle Crown Mining Co. will erect a plant shortly after the Sleeping Beauty is started. In the Rex property the vein has been opened to the 100-ft. level, showing it to be 14 ft. wide, and has an average assay value of $20 per ton.——It is reported that the affairs of the Gueyman have been adjusted and that the mill will resume operations soon. ——The drift on the vein at the Judge is now in 200 ft., on an 18-in. vein of high-grade ore and the winze is down 50 ft. on the same vein, samples of which have assayed over $125 per ton.

ESMERALDA COUNTY

A sill-floor has been established on the 500-ft. level of the Combination Fraction at Goldfield on the orebody opened recently near the Mohawk line, and stoping is now in progress in connection with the extension of the development work. Drifts and cross-cuts are in progress on the 750-ft. level, and the raise that is being driven from the 380-ft. level to re-open the rich shoot that was lost on the 280 is now in ore from which some fair assays have been obtained.

NYE COUNTY

(Special Correspondence).—The Tybo Mining Co., controlled by Max Bernheimer of New York, owns mining property at Tybo, having the Two-G vein that was located about 1864, and which was a profitable producer of silver and lead in early days of high-priced metals. This vein consists of a fault-fissure in limestone, having a westerly strike and a dip of 75° north. It has been opened by a shaft to a depth of 400 ft., and a great deal of the ore has been stoped out to the 300-ft. level for a distance of 1200 ft. on the strike. The vein is said to be as wide as 25 ft. in some places, and narrows to a few inches in others. The ore consists of galena, silver, zinc blende, and iron sulphide, in a lime and silica gangue. It is estimated there are 300,000 tons exposed by present workings. No attempt is now made to ship this ore, because of the long distance from a railroad, Tybo being about equidistant from Goldfield and Ely. An effort is being made to induce the Tonopah & Tidewater interests to build to Tybo and Hamilton, both of which camps could probably supply a considerable tonnage of sulphide ore containing silver, lead, and iron. ——In Tybo district the Metals Exploration Co., controlled by S. F. Hunt, W. S. Larsh, and E. Opdyke, has claims covering 5000 ft. of a vein that is considered the extension of the Two-G vein, on which a number of open-cuts have been made and shafts sunk by which the continuity of the vein is said to have been proved.

Tybo, May 20.

The Independent mill at Manhattan has just completed a run on 39 tons of ore from the Santos-Michael-Schubert lease on the Durant ground and returned to the lessees an average of $40 per ton. Most of this ore was taken out near the surface.——The Canyon mill, which was started a few days ago on ore from the Union No. 9, is crushing 18 tons per day and will increase this to 5 or 6 tons as soon as one of the mullers which was broken some time ago has been repaired. About 300 tons of the ore is to be treated at the mill, all of which is being taken from the lease of Walter Lamb.——The camp of Pioneer is again on the up grade after a dull seasan. The Pioneer lease is working and milling considerable low-grade ore, and the leasing company which was formed to take over the Mayflower holdings is developing the lower levels of the group. ——J. R. Bryan is operating a lease on the K. K. claim and is sacking ore that averages $100 per ton. He has also taken a lease on the Rickard-Garber lease and expects to start shipping ore from that property in a short time.

STOREY COUNTY

The new pumping plant in the C. & C. shaft at the 2300-ft. level has been started again and is apparently working successfully. The column pipes have been lengthened and the water is being lowered rapidly. Thus far no serious obstacles have been found below the water-level in the pump compartment from the old Cornish system, and the shaft is found to be in good condition. As the bottom of the shaft is at the 2650-ft. level it will not require any great time to drain it if there is room for the pumps. The raising of the water from the 2350 and 2450-ft. levels by the auxiliary system has resulted in cooling the workings and it will soon be possible to repair the shaft and get into the 2450-ft. workings of the Consolidated Virginia.——At a recent meeting of the Ophir board of directors the Ophir portion of a joint lease was granted Charles C. Derby to work the Ophir-Mexican croppings on royalties graded from 10 to 25% of the gross value of the ore extracted. The directors also voted to cut down the amount which the Ophir is paying to the Comstock Pumping Association. This cut will amount to 35% and will be made up by the companies operating on the north end.——Good progress is being made on the sub-

Ely, Nevada.

lease which Joseph Dietrich recently secured on the upper workings of the Choliar, and a 4-ft. shoot is being opened. Over 100 tons of ore are in the bins and the tramway to the Butters plant will be started in a few days.

WHITE PINE COUNTY

(Special Correspondence).—The Ely Centennial Copper Co., controlled by John Dern, Samuel Newhouse, H. B. Cole, D. C. McDonald, W. V. Rice, E. V. Vanderhoef, G. F. Boreman, B. G. Hite, and others, is developing its group of claims, situated a quarter of a mile north of Ely, by a cross-cut that starts at the south limit of the property, and runs northerly to cut a series of veins which strike east and west. The heading is now in 850 ft. and in this distance two or three minor veins have been intersected. By driving 200 to 250 ft. farther, it is thought, the principal vein will be struck at a depth of about 550 ft. on its dip. These veins, which outcrop in the limestone cap-rock, having a dip north of about 50°, have been explored to a limited extent by shallow surface workings. In a 55-ft. shaft and a 15-ft. cross-cut from it ore was found assaying 4 to 5% copper and 7 to 10 oz. silver; in a 45-ft. shaft and a 10-ft. drift from it a 15-in. streak of ore was found assaying 30% copper. Another shaft, 35 ft. deep, opened a 4-ft. orebody. Work began here last December, and is in charge of Saul Snyder. A gasoline engine and a 3-drill air-compressor have been installed.

Ely, May 21.

NEW MEXICO

BERNALILLO COUNTY

There has been quite a revival of mining interests in the Sandia and Manzano mountains east of Albuquerque and a number of properties are being explored. In the Soda Springs district the ores are found in a limestone which overlies a granite and are silver-bearing galena with occasional gold-quartz veins. Among the companies actively engaged in developing this district are the Swastika, Bear, Octoroon, and Ruppe. In the Hell Canyon district there is more copper in evidence. The Providence, McKinney, Grey Eagle, and Pittsburg have all opened veins containing a fair amount of copper in the lower levels.

SOCORRO COUNTY

(Special Correspondence).—The Socorro Mines Co. made its regular shipment of concentrate and bullion this week bringing the total production of refined gold and silver to 2000 lb. for the past 30 days.——The mill, bunk-house, shaft-house, and a portion of the shaft timbering of the Mogollon Gold & Copper Co. was destroyed recently by fire, the loss being partly covered by insurance.——During the week the Ernestine Mining Co. milled 704 tons of ore, smelted 6550 oz. of bullion, and shipped 56 sacks of concentrate.——The drift on the 300-ft. level of the Deadwood mine in now 500 ft. from the shaft, and has been in ore the entire distance. The plant has been handicapped by lack of water, but a supply has been obtained at the springs two miles distant, and will be piped to the mine before the mill is completed.

Mogollon, May 21.

UTAH

BEAVER COUNTY

(Special Correspondence).—The Horn Silver mine, at Frisco, is shipping 1000 tons of ore per month. This runs 15 to 20% lead, and 15 to 25 oz. silver per ton, and is mined on the 500, 600, 700, and 800-ft. levels. A small tonnage of zinc is shipped, which is taken from different parts of the same levels. This ore, which is sent to Colorado and Kansas zinc plants, contains 30 to 35% zinc.——The Cupric Mines Co., controlled largely by the same interests that control the Horn Silver, is developing a copper property situated a mile south of Newhouse. A 412-ft. shaft has been sunk and from this some driving has been done in ore.

Frisco, May 20.

JUAB COUNTY

(Special Correspondence).—Shipments from the Mammoth mine, at Mammoth, amount to an average of 500 tons per month of ore assaying 12 to 18 oz. silver, 0.25 to 4 oz. gold per ton, and 3 to 4% copper, the most of which is mined between the 900 and 2200-ft. levels. The matter of special interest concerning this mine is the increase of the gold content of the ores which have been taken out in the last year or two. It is understood that shipments are light at present because of the management's dissatisfaction with the smelting charges. A great deal of development is in progress, with a force of 80 men, and much ore is said to be blocked out. Samuel McIntyre, Jr., is superintendent.

Mammoth, May 21.

SUMMIT COUNTY

At the regular annual stockholders' meeting of the Silver King Coalition Mines Co. recently held in Salt Lake, 998,546 shares of the 1,250,000 were represented. There was no change in the board of directors, and after the election of the board the directors selected the same officers for another year. The company is now engaged in installing an electric haulage system in the property, and the main shaft is being given its first relining throughout in many years. In spite of these improvements, the company is maintaining a steady output of ore, and there has been no reduction of working force by the management.

TOOELE COUNTY

At a meeting of the stockholders of the Ibex Standard Mining Co. and the owners of the Vindicator properties held at Mercur recently the consolidation of the Ibex and Vindicator mines was ratified. The Ibex Standard will increase its capitalization from 125,000 shares to 500,000 shares, par value 25c. per share. There will be besides the original 125,000 shares of the old stock, 175,000 shares to be given to L. E. Kramer, S. D. Gordon, and James W. Sloane, in payment for the three Vindicator claims. The remaining 200,000 shares are to be placed in the treasury and sold to develop the property which has been opened to a depth of 100 ft. developing a vein of lead-copper-silver ore. The company will install a compressor and carry on the development work with machine-drills.

UTAH COUNTY

At a meeting of the stockholders of the Koyle Mining Co., operating the Dream mine near Salem, held in Spanish Fork, the following directors and officers were elected for the ensuing year: John H. Koyle, president; Henry O. Petersen, vice-president; B. F. Woodward, Isaac Hansen, and George Hales, with W. A. Jones, secretary and treasurer. The report from the management was to the effect that there are 30 men working at the property, the mine is in good condition, and the company has sufficient money in the treasury to continue operations all summer.——The Huish Mining & Milling Co., with Payson City as its headquarters, has filed articles of incorporation with the county clerk. The company owns the Lucky Lady No. 1, 2, and 3, Treasure and Treasure No. 1 mining claims in Santaquin mining district which are made the basis of capitalization. The following are the directors and officers: Carl A. Erickson, president; Joseph L. Olson, vice-president; Royal T. Huish, secretary and treasurer, Rudolph Peterson and Alfred Peterson.

MEXICO

CHIHUAHUA

The output of the Rio Plata mine, in the Arteaga mining district, last month was 55,501 oz. of silver, as compared with 53,393 oz. the month before. The management is putting the large accumulation of tailing through the cyanide plant as rapidly as possible before the rainy season. When the stamp-mills are put in operation again on July 1, the amount of silver recovered will increase to its usual proportions. For the year, the net monthly profits are estimated at $20,000.

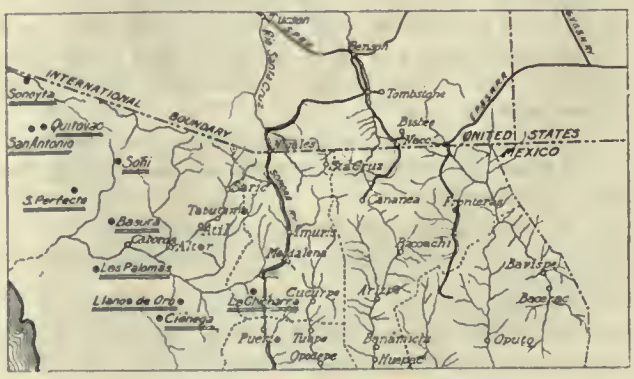
OAXACA

(Special Correspondence).—J. W. Brill, of the Victoria y Tapada Mines Co., has recently taken up 75 additional pertenencias in the Totolapa district.——E. H. Hamilton, general manager for the Virginia Smelting Co., of West Norfolk, Virginia, is making a tour of the Oaxaca camps. Mr. Hamilton is endeavoring to contract for several thousand tons per month of silicious ores, for the smelter he represents.——A. R. Wren, until recently employed with the Monterey smelter, has returned to Oaxaca, and is opening an ore buying agency at Taviche, for the A. S. & R. interests.

Oaxaca, May 20.

SONORA

(Special Correspondence).—The Tharsis York company, the stock of which is held by New York interests, has developed a fine showing of high-grade copper ore in the 130-ft. shaft put down on the company's group adjoining the Pilares mine of the Moctezuma Copper Co., at Nacozari.——Henry C. Carr, of New York, continues development on the body of silver ore in the Antigua mine, which he purchased last December.——A. J. King and associates have re-built



Northern Portion of Sonora.

the wagon-road from the Tigre road to the Cinco de Mayo, recently purchased from Francisco Garcia for $500,000, and operations have been renewed at the mine. The old cyanide plant has been repaired at the Roy mine, and medium ore is now being treated while the high-grade is stacked for shipment to the El Paso smelter.——Frank J. Nichols, of Douglas, and Clifford Robertson, of El Paso, who have an option on the Agua Buena mine, 18 miles south of Nacozari, are now cleaning out the old workings and dewatering them preparatory to examination for Chicago and Kansas City operators.——Herbert Walters has 200 sacks of gold quartz ready for shipment from the Barigon goldfield, recently discovered west of Nacozari.

Nacozari, May 20.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. W. MERRILL is at New York.

C. W. PURINGTON is in San Francisco.

FRANK H. PROBERT is in Los Angeles.

A. H. ELFTMAN was in San Francisco.

E. W. PARKER sails for Europe June 7.

ADOLPH KNOPF has been in San Francisco.

W. H. EMMONS is at Ducktown, Tennessee.

WALTER HARVEY WEED has returned to New York.

FRANCIS DRAKE has gone to Bakersfield, California.

PERCY E. BARBOUR has returned to Salt Lake, Utah.

PHILIP ARGALL has returned to Denver from Mexico.

J. E. SPURR passed through San Francisco this week.

POPE YEATMAN has returned to New York from Chile.

ELWYN STEBBINS has returned from Calaveras county.

NEWTON B. KNOX leaves San Francisco for Brazil today.

VICTOR G. HILLS has returned to Denver from Montana.

H. W. TURNER has gone to Vancouver, British Columbia.

M. M. JOHNSON has returned to Salt Lake from New York.

W. E. DEFTY is in Cochise county, Arizona, on professional work.

EDWIN E. CHASE is in South Dakota examining gold properties.

MYRON K. RODGERS has recently been at Guanajuato, Mexico.

A. C. SPENCER, of the U. S. Geological Survey, is at Ely, Nevada.

HERBERT HAAS is designing the experimental mill for the Inspiration Copper Co. at Globe, Arizona.

E. T. WRIGHT, president of the National Ore Concentration Co., of Chicago, Illinois, is at Joplin, Missouri.

H. V. WINCHELL is in Shasta county, California. He will sail for Europe June 9 to be gone three months.

H. D. MCCASKEY has been visiting the Texas quicksilver district. He is expected soon in San Francisco.

R. B. LAMB, now connected with the Proprietary Mines Company of America, has returned from Elk City, Idaho.

CHARLES S. HERZIG, of the Constant-Herzig Co., is making an extended professional visit to the Porcupine gold camp.

S. E. BRETHERTON has returned to his office in the Mills building from a two weeks' professional trip through Plumas county.

M. K. SHALER will leave Antwerp June 16 for two years in the upper Aruwimi country. His address will be Kinshasa, Belgian Congo.

H. W. HARDINGE is now in Colorado on his way to California on professional business, having already visited the Cobalt district of Canada.

W. H. SEAGRAVE, for several years superintendent of the Veteran mine of the Cumberland-Ely Co., Ely, Nevada, has gone to Prince William Sound, Alaska.

M. J. DALY has resigned the superintendency of the Silver King mine, Park City, Utah, and will be succeeded July 1 by GEORGE D. BLOOD, of Salt Lake, Utah.

H. KENYON BURCH, mechanical engineer for the Miami Copper Co., has just returned from a trip through the northern part of Mexico and Arizona. The trip was made by automobile and covered about 900 miles.

GEORGE E. FARISH, of Denver, Colorado, sailed from Seattle, Washington, May 21, to examine some placer properties in southern Alaska. His address until August 1 will be, care of Postmaster, Juneau, Alaska.

S. B. CHRISTY gave a dinner to GARDNER HUBBARD at the Palace Hotel May 19, at which were present W. C. RALSTON, F. W. BRADLEY, J. R. FARRELL, E. H. BENJAMIN, A. C. LAWSON, M. L. REQUA, CHARLES BUTTERS, ROSS E. BROWNE, CLINTON DAY, and H. F. BAIN.

CHITINA is now connected with Cordova. The Copper River railroad extends from the latter place to Mile 104 at which point connection is made with river steamers running up to the copper region. The *Nizina* made the initial trip May 27 and within six weeks railway connection through is promised.

THE ARTICLE on the genesis of ores by Joseph LeConte, appearing on another page of this issue, is republished in abbreviated form from a lecture of his printed in the MINING AND SCIENTIFIC PRESS in 1871. This was several years before he printed in the *American Journal of Science* the article usually quoted.

ZINC PRODUCTION by the Sulphide Corporation at Broken Hill, New South Wales, amounted in 1909 to 84,689 tons of concentrate containing 46 per cent zinc, 7 per cent lead, and 15 ounces silver. This single company, therefore, took from old tailing more zinc than was produced by the mines of the Wisconsin district, and had some advantage in the silver content. The zinc concentrate, with 6411 tons of lead product, sold for £276,946.

MINORITY stockholders of the Greene Consolidated Copper Company have instituted suit in the New York Supreme Court against Mr. Thomas F. Cole, Mr. John D. Ryan, the Greene-Cananea Copper Company, the Cananea Central Copper Company, the Greene Consolidated Copper Company, the Cananea Consolidated Copper Company, Mr. William C. Greene, and others, praying for a restoration to the Greene Consolidated Company of certain properties alleged to have been wrongfully taken from it, and furthermore demanding an accounting. The Sierra Madre Land & Lumber Company is also involved in the litigation, and an injunction is sought to prevent the suggested merger of the Greene Consolidated with other Cole-Ryan properties. The case is as complicated a tangle as is the Greene maze of company names through which the court must trace responsibility and obligation in the proceedings now beginning.

HAVING JUST CELEBRATED an anniversary of our own we have a particularly keen eye for those of others and have read with especial interest the retrospect with which the editor of *Harpers Magazine* marks the close of the sixtieth year of that publication. 'Harpers' is indeed an institution and most Americans of this generation can not remember when it was not. It seemed to come out of the legendary past—the great past in which 'The War' was a real event, and to go back almost to the time when "your grandfather shot a bear in the front

yard''—for this, the oldest of the great American monthlies, had readers while pioneering was still common. In our own childhood the little cupids on the cover scattered a never ending stream of roses and blew perpetually fresh soap bubbles. Later a time came when in the rush for modernity and the first fierce struggle with newly risen competitors, 'Harpers' lost poise and scrambled. The cupids disappeared and we were grieved and lonely while the magazine followed strange paths. It was not a success, being too much like grand opera in vaudeville or a Salome dance in church—to give the reader his choice of figures. Fortunately the publishers repented and for some time the old magazine, from the cupids on the cover to the ancient jokes in the 'Editor's Drawer', has been restored. We have often, by the way, tried to determine the period of that drawer, so as to predict the return of certain jokes as the astronomer foretells the return of a comet. Success has so far failed to crown our efforts. We think it must be because some heavy jokes filter down through and get out of place when the editor turns the drawer over. However, the old departments, and the old spirit, are back; and that is the great thing. Not all, however, is old; the form and substance are new and as the magazine is now conducted, modern life and conditions are discussed and illustrated in the light of the best traditions. A periodical, as the editor says, is ''not a planned machine, but a living organism''. It is something which the readers make quite as much as does the editor. His, the dignified position of family coachman; he guards the traditions and guides the horse though the latter goes of its own force and at times shows a will of its own. None knows this better than the editor of our centemporary, and *Harpers Magazine*, therefore, is interesting less as an example of what its editor wants to publish than of what the public wants to read. Judged by this test it proves that in the general field of literature, as we have found true in technical journalism, soundness is appreciated and pays.

South American Trade

A dedication number of the Bulletin of the International Bureau of American Republics has been issued, corresponding to the month of May. The number does credit to Mr. John Barrett, the energetic Director of the Bureau, and fitly celebrates the entry into new palatial quarters of this branch of the Government, a branch which is distinctly that of propaganda, looking toward more intimate cultural, social, and commercial relations between the western family of nations. The development of this instrument for promoting pan-American affiliation was due to the patriotic initiative of James G. Blaine. He believed in the power and worth of an American destiny for the United States. As a world-power we find ourselves weak by not being first of all the accepted leader of the Americas. Leaving political errors aside, it is a lamentable fact that we still shut our eyes to opportunity in Latin America. The close ties existing between this country and Mexico are the result of propinquity—which has been responsible for a good many marriages; it has also been promoted by the cordial and forgiving spirit of the Mexican. This friendly alliance should serve as a model for the extension of our influence. We need the commerce of South America; she needs not only our goods but our aid in developing her resources. The spirit of both North and South should unite in the promotion of American enterprise—and we use 'American' here in its broad and proper sense.

The trade of South America today is larger than that of the Orient, but we let it go to foreigners and sit down to that intricate game of chess, Oriental diplomacy. The genius of our people has been that of the pioneer; we could develop South America as could no other nation in the world. We are not so adept in exploiting people as in exploiting natural resources. It is to be hoped that the Bureau of American Republics may become more widely appreciated; that our manufacturers, wholesale merchants, and capitalists may have the opportunities lying to the south of us so driven into their understanding that the campaign may go forward with energy and may bring results. The possibilities of providing enormous quantities of food-stuffs from Latin-America are but feebly comprehended, and this, quite as much as mineral development, needs our attention. We should strike a balance between the output of foods and metals. When that is done a healthier economic condition will prevail in the United States. It will relieve the copper miner, give courage to the producer of lead, and stop the upward soaring cost of producing iron and steel, that now stands $5 per ton above the level of three years ago. A brighter future lies before us if we turn toward the South with the same conviction that animated Mr. Blaine when he called the western nations into conclave at Washington.

Bureau of Mines Appointment

Competition for the position of Director of the new Bureau of Mines is becoming keen. Apparently it is a case of Mr. J. A. Holmes against the field. We have seen no reason to change our opinion, already expressed, to the effect that Mr. Holmes is the best man available for the position. His promotion would insure close connection with the work already begun and his skill and energy are too well known to require comment. He has the powerful antagonism of Mr. J. G. Cannon, Mr. J. A. Tawney, and the ruling spirits of the House organization. He has been altogether too active to suit these eminent standpatters who have repeatedly felt that their hands have been forced in the matter of appropriations for the work under his charge. This opposition may cost him the position, but ability to get appropriations for needed and useful work, will hardly be held by the public to be a proper bar against his appointment. The candidate of the standpat Congressmen is Mr. David Ross, the present secretary of the Bureau of Labor Statistics of Illinois. He is not a technical man but has come up from the ranks of the coal miners and is a man of ability. His candidacy, however, is frankly political and is being urged by politicians, especially Mr. W. B. McKinley, chairman of the Congressional Campaign Committee. Mr. Ross was one of the organizers of the United Mine Work-

ers of America and has many friends, particularly among labor union men and mine inspectors. If the appointment is to be made a political one, he would doubtless give as good administration as possible—but we protest that this is no place for politics. If the Bureau is to accomplish the good for which it is designed, it should be kept as rigorously free from politics as has been the Geological Survey. Miners and engineers should promptly register their protest against any such attempts to defeat the purpose of the work.

Another cause of opposition to Mr. Holmes is his well known friendship and long close association with Mr. Pinchot, Mr. Newell, and Mr. Garfield. No evidence that he has not loyally supported the present Secretary to the full extent that the situation demanded, is offered, and if this is to be seriously urged it begins to look like a war of proscription against Mr. Pinchot and his friends; a war which could only result in great damage to the public service and which would be certain, incidentally, to react disastrously on the administration. Mr. George Otis Smith, Director of the Geological Survey, is opposed to his appointment, and favors Mr. E. W. Parker, the well known statistician of the Survey. While having a high opinion of Mr. Parker and his ability, we do not consider this a good selection. There has been some jealousy and disagreement between the men of the Technological and the other Branches of the Survey. Some of the members of the Survey have been opposed to the organization of a Bureau of Mines at all, and Mr. Parker has not been in harmony with the plans and purposes of those who have been active in securing the establishment of the new Bureau. His appointment will certainly be considered to be an attempt to control the situation in the special interest of the Geological Survey rather than of the mining industry. Bureau and Department jealousy works havoc enough at Washington and the better part is to look beyond the present and to measure the good to the country and the work rather than to a particular Bureau. We have no desire to insist further than that the best possible man be appointed to the new post. Among the men who have been mentioned no one, we think, so measures up to the position as does Mr. J. A. Holmes.

Copper Prices

Regularization of the copper market has been much demanded, but the difficulties in the way have loomed large. It is beginning to appear that stability will come in the good old fashioned way through operation of the ordinary laws of trade rather than through mergers and combinations. The result is likely to be more satisfactory to consumers than producers, though not necessarily bad for the latter. At present, production is running about 10 per cent ahead of consumption. The visible stock of metal, while large, is not out of proportion to the volume of business transacted. It has, however, the great disadvantage from the point of view of those who would raise prices, of being all visible. In the new order of things the producer and not the consumer carries the stock. The great copper companies have got into the position of merchants who carry shelves stocked with goods and must perforce wait for customers. In the meantime the pressure to sell is enormous and steady and back of it lies a story of the new order of things in mining.

In former times mines generally paid for themselves. The prospector with his grub-stake was succeeded by the partnership or the local development syndicate, and it in turn by the company, but all along the way the amount of money brought in from outside was small. Usually it was not beyond the means of some single group whose members might readily keep informed as to intimate details and were thus ready to accept temporary loss of interest for the sake of future profits. With the development, however, of the larger mines of today, and especially of the porphyry coppers, it has become necessary to advance large sums of money and to resolutely face the fact that returns can not be expected for some five or six years. This narrows the field. Relatively few people have the necessary money and are ready to invest on these terms. The pressure to get the properties on a dividend basis has naturally been great, and since to permit full development usually requires repeated bond or stock issues, the pressure to keep dividends going has been greater. To get and keep a clientele of investors in these properties it is necessary to make the securities good collateral as promptly as possible. Dividends and listing on the stock exchange are potent factors, but especially dividends. The men who control the properties are frequently not the main owners and even the money they put up is often borrowed, with the stock or similar securities as collateral.

The new Ray is capitalized at $12,000,000, Nevada Consolidated has $9,923,530 outstanding, the larger Utah stands at $25,000,000, and the new Anaconda at $150,000,000; a far cry that from the simple prospect of early days. As modern business is now organized such sums are only commanded through Wall Street, and Wall Street has no continued interest in non-dividend paying properties. Whether the stock be held for real investment or be counted merely as chips in the game, dividends are essential. Talk of curtailment is idle. Each company must produce and sell, making what profit it can, else the promoters and managers lose control and their following; the latter a valued asset for the future. Therefore the Butte mines consolidate, economies are effected, and such copper as can be, is produced on a 9-cent basis; that being the price fixed by the effective competition of the porphyries. If prices rise, a larger amount of higher-priced copper will be made; if they fall, a small amount of lower-priced. In this the Butte mines but exemplify the whole. Here and there a single property may suspend but the big mines can, within limits, produce some copper at any price fixed by the market. The scale of modern operations is so large and new copper mines of any importance are so slowly brought to production, that only slow changes in copper prices are likely to occur. Manipulation may occasionally and for short times raise copper to an artificial price, but regularity of price, the best basis for industry, seems likely to rule.

Australia's Premier Tin-Mine

By John Plummer

Each of the Australian States appears to be richer than the others in some form or other of mineral production. Thus Victoria formerly, and Western Australia lately, leads in the auriferous output; New South Wales in silver and coal; South Australia in copper; Queensland in copper-gold; and Tasmania in tin and galena. In Tasmania Mount Bischoff and the Briseis mines are among the richest in existence. The former was discovered in 1871, and is worked largely as an open quarry, a considerable proportion of the hill having been removed in the course of development. From the very outset the mine has been a consistent producer until some little time ago, when it was reported that only a few months work at a largely reduced rate of output remained. This was serious news for the shareholders, who, up to date, have secured over £2,124,000 in dividends. Considering that the number of shares is limited, only 12,000 having been issued, of which 4400 paid up to £5 each were given to the discoverer, while on the remaining 7600 shares not more than £1 each was paid by the purchasers, the mine may be regarded as one of the most profitable in the Commonwealth. It paid almost from the start. Of the £7500 actually subscribed, £1500 was paid to the discoverer, the remaining £6100 being sufficient to commence working operations.

Mount Bischoff is described as being a huge peak rising several hundred feet above the township at its base. The main outcrop is an irregular porphyry dike, trending approximately east. "From the township vast quarry-like excavations can be seen on the southern slope of the hill. These give some indications of the extent of the mine, the white faces being a land-mark for miles. They are, however, only a minor portion of the workings, as beyond them to the north, but shut out from view by a strip of rock, lie the brown faces from which immense quantities of tin have been won in the past. Excavations here run up to 190 ft. in depth and hundreds of feet in length." Mining is also carried on extensively underground. The brown faces consist very largely of iron-stained sand material cemented together by limonite derived from the decomposition of the pyrite in the adjoining rock. Detritus is described as being most interesting, lying under a capping of solid rock in places. There are also large deposits of granular gossan, carrying rich pockets of tin. These are of use in maintaining the high average grade of the ore milled. Sulphurous smelling bands of pyrite also add to the variety of coloring in the mine, "even if they do not make working conditions pleasant."

When it was rumored that the mine was becoming exhausted, the scientific adviser of the company, J. D. Millen, now general manager, decided upon a thorough investigation, and determined that possibly some of the evidence relied on by the miners for guidance was incorrect. He therefore commenced collecting evidence respecting the genesis of the ore. This was a most elaborate process, involving a careful microscopic examination of the porphyries to ascertain whether supposed barren rock carried elements necessary for the existence of staniferous ore, as did the rocks in which the ore was found. In his researches Mr. Millen followed on the lines of Daubeè's theories with regard to the sublimation of vapors in connection with the deposition of tin. The result was to demonstrate conclusively that 'topazization' noticeable in rocks known to contain tin ore existed also in porphyries which are supposed to carry no tin. The next step consisted in commencing a system of prospecting with a view to ascertaining, after microscopic work, which of the porphyries did and which did not show topaz. The results were most satisfactory, and the mine, instead of having only a few month's life, has now reserves proved for at least another ten years, based on the present output of about 90 tons of tin oxide per month, and the ore-faces generally promise that these reserves will be increased. It is, in a sense, the story of the waste heaps at Broken Hill over again. But for the investigations conducted by Mr. Millen the Mount Bischoff might have been abandoned a few months hence and forgotten like many other mines in the Commonwealth. Some have supposed that Mr. Millen simply discovered fresh deposits where tin-bearing rocks were supposed to have been worked out, but he explains that the ore is found at many points where it was assumed not to exist. Wherever the topazization of the porphyries has occurred tin is to be found. The success of his investigations induced Mr. Millen vigorously to explore the mine in directions where work had been suspended. He drove through masses of ink-black decomposed pyrites, notwithstanding the repeated assertion that they indicated the termination of the run of good ore. Boring was carried on below the floor, cross-cuts made to ascertain the existence of unsuspected orebodies, and a lot of other work done, with the result that the continued productiveness of the mine became assured, and there will be no interruption in the payment of dividends. The whole milling plant has been remodeled, and Mount Bischoff made practically a new mine. It has already been enabled to double its output, and is one of the finest examples of science applied to mining yet afforded in Australia.

An immense amount of work has been done by Mr. Millen and his predecessor. "The country," we are told, "is so abrupt, and the Mount itself of such extent, that a lengthy inspection is necessary to appreciate the amount of work effected. For instance, huge stanniferous gossan boulders exist, not only on the southwestern slope, but also far away on the opposite or northern slope. Do these point to the fact that they have been shed from some lode formation on that side of the hill? If so, further deposits of tin-bearing ore may exist there to be opened up." Practically, there exist great possibilities on the northern side, which still remains unworked save near the summit. Lately, however, the productiveness of Mount Bischoff has been exceeded by that of the Briseis mines, the dividend paid by the former in 1908 being £36,000, and those of the latter amounting to £112,500.

CANADIAN MINING INSTITUTE MEETING

The eighth general meeting of the Western Branch of the Canadian Mining Institute was held at Grand Forks, British Columbia, on May 26. W. Fleet Robertson, of Victoria, B. C., Provincial Mineralogist, who is this year's chairman, presided, and E. Jacobs, branch secretary, was also in attendance. Several papers were read as follows: By O. E. LeRoy, on 'The Geology of the Ores of Phoenix Camp, B. C.'; by L. Reinecke, on 'Silver and Gold Deposits on the West Fork of Kettle River'; by Charles Camsell, on 'The Mineral Resources of a Part of Yale District, B. C.' The writers of these papers are members of the staff of the Geological Survey of Canada. A summary of O. E. LeRoy's account of the geology of Phoenix may be given as follows: The mineral zones in which the Granby and other large mines are situated are in structural basins with a well marked floor of highly siliceous rocks termed jasperoids. The mineral zone itself consists mainly of garnet and epidote, with a few other lime-iron silicates in smaller quantities. Water and gas, highly heated, carrying iron and silica, have combined with the lime to form these silicates, which are essentially self-fluxing. The orebodies are enormous, irregular, lense-shaped masses, from a few hundred to more than 2000 ft. in length, with a width of 100 ft. and more. These lie, as a rule, on the bottoms of the basins with the jasperoid foot-wall. The hanging wall, unlike the foot-wall, which is structural, shows no clear definition, the ore gradually grading into the gangue minerals. The average ore is a copper and iron pyrite, evenly distributed with hematite, and, in certain places, magnetite in a gangue of garnet, epidote, quartz, and calcite. The topography of the country and the attitude of the orebodies favor the most economic methods of mining. Some of the orebodies do not outcrop at the surface, so can only be found by diamond-drilling. Throughout the Boundary district there occur isolated areas of limestone replaced in part by the above-mentioned minerals, so it is possible that careful prospecting will lead to the finding of other orebodies of commercial importance. Charles Camsell described the Yale district as being for the most part in the belt of interior plateaus but embracing also the northern prolongation of the Cascade mountains. The metallic ores lie generally in the sedimentary rocks of Cambrian, Carboniferous, and Triassic ages, and are genetically connected with the plutonic eruptive rocks. The volcanic rocks, on the other hand, rarely hold deposits of economic value. The Tertiary sedimentary rocks generally yield coals, but the Cretaceous sediments have not been shown to contain any. The mineral resources of the district include ores of gold, silver, platinum, copper, lead, iron, zinc, chromite, mercury, and a few others of less importance. Of the non-metallic substances, coal is by far the most important. Gold has yielded most largely as yet. The annual output of placer gold has for many years been decreasing. The production of lode gold, however, is increasing and is now more than $500,000 per annum. The total production of platinum to be from 11,000 to 20,000 ounces.

SOUTHERN PACIFIC AND OIL

*Proceeds of the sale by the Southern Pacific Co. of the valuable oil properties included among its 14,000,000 acres of unsold lands, in whatever form it may be made, bid fair to run into millions. Another and prominent feature of the Southern Pacific's position in the California oil situation is yet to be considered. It will still control the oil it has sold, by virtue of its intrenched position as the leading marketer of California oil. Through its $20,069,003 of the $40,000,000 stock of the Associated Oil Co. the Southern Pacific controls a vast estimated storage of over 600,000,000 bbl. of fuel oil on grounds of the Associated Oil Co., entirely distinct from the lands it proposes to sell, which are lands granted to the Southern Pacific Railroad Co. But what may be accepted as the even better reason why the Southern Pacific will not part with its Associated Oil stock is the fact that the Associated company is the owner and operator of a pipe-line system through which is marketed 40% of the entire output of California.

California produced during 1909 some 56,000,000 bbl. net of oil, or approximately 30% of the output of the United States, which yields 70% of the world's production. With California's importance as the chief source of fuel oil rapidly increasing, it would seem a foregone conclusion that the Associated will not easily yield its relative importance as the leading marketer of California oil. In this connection an official of the Associated points to the $8,445,978 expended on development from the earnings of the company since its organization in 1901, this in addition to the proceeds of approximately $28,000,000 par value of securities also consumed in development.

With the Kern Trading & Oil Co., a Southern Pacific subsidiary, the Associated has joint control of the Associated Pipe Line Co., capital stock $7,000,000, no bonds, which owns and operates a 280-mile pipe-line from the Kern field to Port Costa on San Francisco bay, daily capacity, 16,000 bbl.; and a 256-mile pipe-line from the McKittrick field by way of Coalinga to Port Costa, daily capacity 16,000 bbl., together with extensive terminal facilities at Port Costa. The 72-mile section from the McKittrick and Midway fields to Coalinga is to be placed in operation about July 1 next, the remainder of the line being already in operation. These pipe-lines are valued on the company's balance sheet at $7,142,279.

All of the $4,222,461 outstanding stock of the Associated Transportation Co. is owned by the Associated Oil, the remainder of an authorized issue of $10,000,000 being held in treasury to issue for the acquisition of new ships, pipe-lines, and other equipment. The company has no bonded indebtedness. It owns a 106-mile pipe-line from Coalinga to Monterey, about 100 miles below San Francisco on the coast, daily capacity 13,000 bbl.; terminal facilities at Monterey; a 50-mile pipe-line from Santa Maria to Gaviota, Santa Barbara county, daily capacity 18,000 bbl.; terminal facilities and a refinery of 7000 bbl. daily capacity at Gaviota.

*Abstract from *Boston News Bureau.*

Lithium and Its Sources

By Frank L. Hess

*Lithium is one of the alkaline metals and is the lightest known solid element. Its specific gravity (0.595) is so low that the metal will float on kerosene. Although lithium minerals are not at all common, notable quantities of several occur in the United States at widely separated points. Traces of lithium are found in nearly all igneous rocks[1], and in many mineral springs. In all places where lithium minerals occur visibly, they are associated with granitic rocks and generally, if not always, with the latest phases of granitic intrusions, either in pegmatite, or in granites and adjacent rocks which have been altered by hot gaseous emanations, a process known as pneumatolysis or pneumatolytic action. In some places large masses of lithium minerals which can be worked commercially are found in the pegmatites; in the altered granites only minor quantities of lithium are found. The places of occurrence are practically those of tin, but the largest deposits of tin are found under the conditions which mean small deposits of lithium; that is, where pneumatolysis or other last fluidal processes accompanying the intrusions of granite have acted largely. In the pegmatites which carry large quantities of lithium, the tin content is generally small. Tourmaline, wolframite, columbite, beryl, and many other comparatively rare minerals generally occur in lithia-bearing pegmatites.

The most important lithium minerals are the following: *Lepidolite*, a lithium mica, ordinarily containing from 4 to 5% of lithia. *Lithiophilite*, a phosphate of iron, manganese, and lithium, containing 8.15 to 9.36% of lithia. *Triphylite*, a variety of lithiophilite, containing little or no manganese. *Spodumene*, a silicate of aluminum and lithium, containing from 4.49 to 7.62% of lithia. *Amblygonite*, a fluo-phosphate of aluminum and lithium, containing ordinarily from 7.92 to 9.52% of lithia. While there are a number of other lithium minerals, they are unimportant as a commercial source of lithia, either containing too small a quantity of lithia, or occurring in deposits which are not large enough to be worked commercially.

In color lepidolite is glistening white, yellow, violet, lilac, pink, rose red, or gray. It is generally in small indistinct plates, but in places forms six-sided crystals belonging to the monoclinic system. At Pala, California, and at other places, it forms an outer rim around muscovite mica plates several inches across. In this country lepidolite is found in Hebron, Auburn, Norway, Paris, Rumford, and other places in western Maine; in South Dakota in considerable quantities in connection with the tin deposits of the southern Black Hills; and in great amount with rubellite, a beautiful red tourmaline, in the neighborhood of Pala, southern California. At the Stewart mine, two miles northeast of Pala, in 1907,[2] there was exposed a lenticular mass of delicately tinted, lilac colored lepidolite, 90 ft. long, and 20 to 25 thick, in which a tunnel 125 ft. long had been driven. Several hundred tons were mined and shipped from this deposit. In the lepidolite, rubellite, which also contains some lithia, forms beautiful radial aggregates. Many thousand specimens have been obtained here for mineral collections all over the world. After the spodumene and amblygonite deposits of South Dakota were opened up it no longer paid to operate the Pala deposits. In the Black Hills also lepidolite has been worked to a small extent for its lithia content. There are many other localities where lepidolite is found in occasional flakes or small masses. At Wakefield, Quebec, it occurs in plates several inches across. Other lithium micas are cookeite, zinnwaldite, cryophilite, polylithionite, and protolithionite.

Open Cut in Etta Mine, Keystone, South Dakota, Showing Impressions Left by Spodumene Crystals.

Lithiophilite occurs in small amount at Peru, Maine; Grafton, New Hampshire; in the tin-bearing pegmatite dikes of Kings Mountain, North Carolina; near Pala, and in the Black Hills. In the Black Hills, lithiophilite occurs in many pegmatite dikes, probably in all which carry lepidolite, spodumene, or amblygonite. The masses are very irregular in size and shape, and are of a brownish or blackish color, the latter probably resulting from oxidation of the manganese. In places, both in South Dakota and North Carolina, surfaces are coated with a fine purple film of purpurite, a decomposition product. In the Etta mine, pieces of lithiophilite 6 to 8 in. diameter have decomposed centres partly filled with lilac, blue, and dark green vivianite, probably accompanied by another iron phosphate, dufrenite.

[1]Clark, F. W. 'The Data of Geochemistry'. Bull. U. S. Geol. Surv., No. 330, 1908, p. 17.

[2]This statement is made on the authority of W. T. Schaller, U. S. Geological Survey.

In both the Etta and Peerless mines, lithiophilite occurs in such quantity that while mining for other minerals a few tons may be gathered together for shipment each season. As stated, it contains from 8.15 to 9.36% of lithia, and if it occurred in large amount would be equal to amblygonite as a lithia ore. When it contains little manganese it is lighter colored and is called triphylite. Probably both varieties occur in the Black Hills. Alluaudite is a mineral closely related to lithiophilite, but of no commercial value.

Spodumene occurs in the same general localities mentioned for lepidolite, but is found in greatest quantity in the pegmatites of the Black Hills. In the Etta mine, 1½ miles south of Keystone, the crystals of spodumene are immense, reaching 42 ft. in length with a cross-section of approximately 3 by 6 ft., and so far as known are approached in size by no crystals outside of the Black Hills. In many places mining has exposed cross-sections which are rectangles with truncated corners. It is said that 37 tons of spodumene was mined from one crystal. The dike at the Etta mine is oval in shape, and about 100 by 150 ft. in horizontal measurement.

Tin was first discovered in the early eighties in the Black Hills at this mine, and previous to that the mine had been worked for mica. After the Harney Peak Tin Mining, Milling & Manufacturing Co. was organized, a large mill was put up near the property, and an unsuccessful effort made to exploit the tin. It has been stated that one reason for this was the mistaking of columbite for cassiterite. At any rate, after a very short run, operations ceased, the company went into the hands of a receiver, and the mine lay idle for a number of years. Meanwhile, spodumene had attracted attention as a source of lithium, and the court allowed the receiver to lease the claim to be worked for this mineral. The crystals are considerably decayed, and have an earthy appearance and the odor of a fresh clay pipe. Owing to the decay, the crystals have a fibrous, woody structure, and from this and their size, the workmen ordinarily refer to them as 'logs', which they much resemble. Along cracks in the spodumene cassiterite has been deposited and is evidently of later crystallization.

For a number of years the deposit has been worked by the Standard Essence Co., of Maywood, New Jersey. No amblygonite has been found in this deposit though in the Peerless claim, half a mile away, it occurs in large masses, with some spodumene. Spodumene is found in many other dikes of the region, in some places, such as that on the Dewey claim at the northwestern foot of Harney peak, and on the Louise claim, one mile south of Oreville, it is fresh, glassy, and hard. On these latter claims the crystals are smaller, reaching only 2 or 3 ft. in length, and a few inches in breadth and thickness. An occurrence is reported from the vicinity of Custer in which cross-sections of crystals are exposed that rival those of the Etta mine.

Although amblygonite is found in crystals reaching a few inches in length at Pala and several other places in the United States, and in foreign countries, no other large deposits are known. No work was done at the Etta mine during 1909 beyond shipping several carloads of 'spod', as it is locally called, which had been mined during 1908. Spodumene of an emerald green color, when fresh enough to be glassy and clear, is known as hiddenite, and sells for very high prices as a gem. As with most gems, the price is largely artificial and they are merely held until sold for the amount asked. It is found at Hiddenite, North Carolina. A beautiful pink or lilac variety found near Pala and Rincon, San Diego county, California, is known as kunzite and also sells at high prices. Some jewelers say that the stones lose their color, probably from strong light, and one jeweler showed the writer a stone which he said had faded in a comparatively short time. Kunzite, when of a good clear color, is one of the most beautiful of gem stones. In hiddenite and kunzite the refraction of light is high, so that the stones have considerable brilliancy. Both varieties are reported from Madagascar.[3]

Beta-spodumene, cymatolite, and killinite are minerals formed through the alteration of spodumene, which have only mineralogical importance. The minerals petalite, castorite, and hydro-castorite, are related to spodumene but are without commercial value as a source of lithia.

Amblygonite is found in the same general localities that have been noted for lepidolite and spodumene. It contains a higher percentage of lithia than any mineral except lithiophilite, and, as it occurs in large masses which can be easily and cheaply worked, other conditions being equal, it is more valuable as a source of lithia than either of the other minerals. As found in South Dakota and California, it is a pearly white mineral with one good cleavage, and looks like a very fresh feldspar. In other places it has pale greenish, bluish, yellowish, or brownish tints. Recently, Herman Reinbold, of the Western Chemical Reduction Co., Omaha, Nebraska, mined a large deposit of amblygonite of excellent quality on the Peerless claim, one-half mile northeast of the Etta claim, and one mile from Keystone, South Dakota. As opened in the fall of 1908, the shoot or mass was about 20 ft. wide, and had been excavated more than the same amount in depth and in length. Since then this mass has been mined out, and is said to have produced a total of 900 tons. Amblygonite in fair amount is found on the Tin Queen claim, 1½ miles east of Oreville, from which about two carloads are said to have been shipped by Mr. Reinbold several years ago. At present the company is mining from a claim a short distance east of the Peerless, where the mineral, accompanied by spodumene, is said to occur in large amount. There is some amblygonite on the Ingersoll and probably on other claims in the vicinity. In the Pala locality a mass containing a few hundred tons was mined several years ago, but no other large mass has been found. Amblygonite has been mined at Montebras, central France, in a tin mine; the San Finx tin mine, northwestern Spain; near Perig, Saxony, and in 1906, about 45 tons, valued at $1000 were exported from northern Australia.

[3]Sterrett, Douglas B. 'Mineral Resources of the United States, 1907'. U. S. Geol. Surv., Vol. II, 1908, p. 826.

After opening up the amblygonite on the Peerless claim, Mr. Reinbold began to lower the price of lithia until from $2 to $2.50 per pound, it had tumbled to 50c., and later large quantities were sold at an even lower price. The market for lithium minerals and salts in respect to uses, manufacturers, and consumers, has been a very restricted one. The product most manufactured is lithium carbonate, and for some time it was not known what was being done with the bulk of the salt. It was known that a part was used in the manufacture of artificial lithia waters and for medicinal purposes, but this would account for only a few hundred pounds per year. It is now known that it is used in a storage battery of Edison's manufacture. A small quantity probably also goes into the manufacture of fireworks. Lithium (the metal) is so easily oxidized that no practical use is known for it. Of the lithium salts, lithium bromide is used in photography and in medicine, and various other salts are used for lithiasis (gravel), arthritis (inflammation of the joints), chronic rheumatism, and gout.

By many, the use of natural lithium-bearing waters for various diseases is highly valued, especially in lithiasis, and a large trade is carried on in water from 'lithia springs' in many parts of the United States. Concerning the medicinal use of lithium-bearing spring waters, Haywood and Smith[4] make this remark: "While lithium seldom or never occurs in waters in large enough quantities to be a predominating basic constituent, still it does often appear in sufficient quantities to have a decided therapeutic action. These compounds are active diuretics and form a very soluble urate which is easily eliminated from the system. Waters of the above class, therefore, find their greatest application in the treatment of rheumatism, rheumatic tendencies, and gout. In cases of gravel and calculi they are also valuable disintegrating agents".

The most widely known of these waters are probably from the springs at Saratoga, New York, and they are also of the best. The mineral content of springs varies from time to time owing to drought, excessive rainfall, or other conditions, so that analyses of samples taken at different periods do not agree closely, especially in the lithium content. As sampled by Haywood and Smith,[5] the Carlsbad water of Saratoga carried 31.8 parts per million of lithium chloride. This water was the richest in lithium of any analyzed by the authors who gathered samples of the prominently advertised lithia waters of the country for testing. Some of these waters contain so little lithia that barrels of the water would have to be drunk to get a dose of lithia. The proprietor of one spring, in order that his guests might have no doubts as to the lithium content of the water, imported lepidolite from a well known locality and scattered it carelessly around the spring, even putting some in the forks of a tree. But the man who really knew rocks came along one day and the fraud was made known.

Methods of Pulp Agitation

By Lloyd M. Kniffen

It is good to see that more attention is being paid to the question of agitating pulp during cyanide treatment and that the metallurgist is not now limited to centrifugal pumps and arm agitators. The waste of energy with these methods is enormous. At one plant 40 hp. are required to agitate a pulp containing 100 tons of dry slime, and power there costs 3c. per horse-power hour. The proper choice of an agitating device depends upon the amount of aeration that the ore requires during treatment, and, therefore, upon the form in which the silver is combined, because, the gold usually submits to any treatment required for the silver, and for this reason no one system is applicable to all ores.

In the following analysis I have tried to arrange the various systems in the order of their aerating capacity, for it should not be forgotten that length of treatment required with any system must enter into the question of cost. A system which would extract the silver from an ore in half as much time as some other system, would have an even chance, though it required twice as much energy.

If the ore only requires that fresh molecules of cyanide be brought continually to the particles of metal, and that the air which is included in the solution be sufficient for the reaction, there is no system at present better than arm agitators, raised a few feet above the bottom of the tank, and driven at 800 linear feet per minute. At this speed no difficulty is experienced in starting, because, during operation the pulp is picked up far enough below the arms to leave space for the sand to settle when the arms are stopped. This method is giving excellent results on many Mexican silver ores, but other ores require a varying amount of aeration. For these other systems of agitation must be used. As one means, the centrifugal pump in conjunction with arms does the work, and the pulp often contains as much as 2% atomized air which is discharged on standing. The disadvantages of high cost of operation, and wear on linings, however, usually prohibits its use. By introducing compressed air into the suction more aeration may be obtained with less expenditure of energy.

The Pachuca system is the cheapest in operation of all that have been devised. A pulp containing 100 tons of dry slime and 150 of solution, can be treated with 4½ hp. This is cheap work, but as an aerator the Pachuca tank is not in the first class, as the pulp usually contains little absorbed air. Most of the air used for agitation escapes as large bubbles at the top of the column-pipe, and does not come in coutact with the ore. The expansion of this large quantity of air abstracts heat from the charge. Also Pachuca tanks as at present built leave room for a large amount of sand to accumulate on the sides of the cone, which does not get agitated, and the circulation takes place in a limited cross-section. When the tank is emptied part of this sand slides out through the discharging pipe so that its true amount it not really known. Where Pachuca tanks are not

required for such aerating function as they can perform they should not be installed, because they present the disadvantage of introducing air that is not available for treatment, but from which carbon dioxide enters the solution and precipitates and wastes the lime. Part of the calcium carbonate formed is deposited on the canvas of the filter-presses, if these are employed, and in this way makes an unnecessary cost for acid treating. Herein lies a hint for selecting an agitator, namely, employ that system which will give the proper amount of aeration but no more, as an excess will be expensive.

The Hendryx system gives good aeration, and on one ore is doing more rapid work than the Trent. This function is principally due to the use of the apron, around the column-pipe, whereby a new quantity of pulp is being continually brought into contact with the atmosphere. It might be of interest that this apron has been used at one plant on Pachuca tanks, and it is deserving of an extended trial on silver ores in Mexico. The principal disadvantages of the Hendryx agitator are: high cost of installation, high cost of operation, 18 hp. per 100 tons of dry slime, and cost of wear of the moving parts.

Next in order, as an efficient aerator, I would put the system employed at the Pinguico mill at Guanajuato, Mexico. There the treatment-tank is equipped with arms for agitation and an air-pipe with a coupling, to allow rotation, is taken down the shaft and out upon the arms. Small vents let the air escape, and the motion of the arms breaks it up and gives intimate contact of the pulp with the air. The amount of air used is thus easily controlled.

The Trent agitation system is one in which the pulp is taken from the top of the charge and pumped through arms, which revolve near the bottom, due to their reaction from the force of the flow. This gives excellent aeration. The air if admitted through the centrifugal pumps gets thoroughly atomized and uniformly mixed with the pulp. The quantity of air can be regulated so that a small excess will be evolved gradually over the whole top of the charge. The disadvantage in the use of centrifugal pumps is with their low efficiency. Also, as many ores admit of treatment with a pulp of heavy consistence (sometimes one of solution to one of ore), it is hard to see why the sand would not reach the top of the charge and then the wear on the pumps would have to be contended with. Per 100 tons of dry slime 12 hp. is required for this method. The pulp contains 3% of free air in the tank. The Just process seems to employ an excellent principle, although it has not been tried long enough to prove it thoroughly. Both this and the Trent agitator possess the advantage of being able to be installed in existing tanks with only slight modifications. In the Just system a false bottom of patented porous brick is laid, which supports the charge. Air from a rotary blower is forced beneath the brick and finds its way through the pores. In this way it becomes very finely divided and agitates the charge uniformly. It is claimed that pulp 9 ft. deep can be agitated with 5 lb. of air. If the mechanical difficulties of holding the brick securely, and keeping the pores open, can be overcome this process ought to have a wide application, as many silver ores need all the aeration possible. Where it is necessary to carry a high protective alkalinity it might be necessary to acid-treat the bricks which would be a troublesome operation.

Some plants are now making steam for the purpose of heating the charge during treatment. The condensation of this steam dilutes the charge and decreases the quantity of water that can be used for washing on the filter-presses. The use of pre-heated air for the agitation would overcome these difficulties, and offers a good field for investigation. For overcoming the difficulty in the use of air in treatment tanks, namely, the precipitation of the lime, an apparatus using calcium oxide or other means for removing the carbon dioxide from the air before compression might be a valuable adjunct. Some of the foregoing remarks may meet with objections but they are open to discussion. They may help to clarify a subject which is more unsettled than any other branch of cyanidation at present.

Low-lift pumping is now done so generally by centrifugal units operated by reciprocating engines that the use of steam turbines for the steam-ends has been an inevitable development of the field for some time. A number of years ago Dabney H. Maury read a paper on such units before the American Water Works Association, and since then a few of them have been put in service, with results which are kept remarkably confidential by everybody in a position to understand their details. That there has been some measure of success in connection with such plants is shown by the fact that at least one steam-turbine manufacturer is now urging for certain uses a unit consisting of a submerged centrifugal pump with a vertical axis carrying a vertical steam turbine at the upper end. It is claimed that the bearing for such a unit can be built in a thoroughly reliable way which will cause no trouble in operation, but up to the present time the engineers to whom the unit has been proposed have hardly been favorable toward it. It is one of those novelties which, in order to be introduced successfully, must be presented in a particularly careful manner and backed by long-time guarantees, leaving no points open for serious criticism. The importance of low-lift pumping apparatus is increasing rapidly.—*Engineering Record.*

Drillings should not be relied upon too closely in estimating the value of ground prospected. Raises have been put up on a number of holes both at Ray and Miami, and while in some cases the drill returns and those from the raise check satisfactorily, in other cases poor results are obtained. A variation as great as 0.5% has been found to occur in ores averaging 3% or less. As a rule, the drill returns are low, a fact which is rather hard to explain. It is possible that the heavy sulphides tend to settle in the bottom of the hole and in fissures and pockets in the sides where they are undisturbed by the churning of the tools. In unreased holes, cavings from the overburden would lower the percentage of copper, and on the other hand, it has been found that after the hole has passed through a sulphide body, the samples may still indicate good ore. Under such conditions, casing changes the grade of samples materially.

Shaft Sinking at the Giroux

STAFF CORRESPONDENCE

The Giroux Consolidated Mines Co. at Ely, Nevada, under the general management of Frank P. Mills, has finished its new 5-compartment shaft at Kimberly, in Ely district, its location being on the southern slope of Old Glory hill, 750 ft. southwest from the company's Alpha shaft. The size of the new shaft, which is in limestone, is 17 ft. 2¾ in. by 10 ft., measured inside the timbers. A cage compartment is 10 ft. by 5 ft. 8 in.; two skip compartments are each 5½ by 5 ft.; two others, for pipes and ladder-way, are each 5 ft. by 4 ft. ½ in. In opening this shaft 948 ft. of the work was done by raising, the starting point having been on a cross-cut that had been driven from the 1000-ft. station of the Alpha shaft. After cutting a 14 by 18-ft. station and installing an air-hoist, the raising began July 5, 1909. The raise was made 13 by 12 ft. in the clear, was supported by timbering in square sets, which divided the space into four compartments, the one at each end being used as a chute. The chute lining was braced by 8 by 8-in. stiffeners. The lagging on the wall-sides of the cage, ladder, and pipe compartments was likewise stiffened by 4 by 6-in. timbers. Everard Arnold, construction engineer at this property, in describing this work, says: "Over the two centre compartments the last two sets were always bulkheaded with 8 by 12-in. timbers, and from the lower bulkhead the cage sheave-wheel was suspended. After a round of holes had been blasted and the loose ground picked down, the average time required to hoist, plumb, and block a set of timbers was 2 hr., although the operation was occasionally performed in 1 hr. 30 min. When possible the chutes were kept almost full in order to minimize the chances of injury should men have happened to fall. For the purpose of protecting the lower timbers of the chute, breakers or platforms of 10 by 10-in. timbers were spiked to the girts at intervals of seven sets. On these breakers the rock piled up and formed its own slope. Trouble was often caused by large rocks dropping into the chute, and on reaching the gate they would have to be blasted."

The air-hoist was used in raising timbers from the foot of the raise; and two pressure blowers, running in tandem, served to keep up ventilation. When the raise reached a place as high as the 770-ft. level from the Alpha shaft, a connection was made and this level then served for the removal of rock and as an entrance to the raise instead of the 1000-ft. level. In accomplishing the 948 ft. of raising, three shifts per day for 180 days were required, the work having been in direct charge of William Hogan, mine superintendent. The raise cost $71.21 per foot, classified as follows: raising, $16.69; tramming, $5.09; timber framing, $1.76; blacksmithing $1.19; machine shop, 11c.; teaming, 54c.; air-compressor, $10; supplies, $17.24; hoisting, $15.15; proportion of general underground expenses, $3.44. As it is estimated that 75% of the timber used in raising will be available for other work, the ultimate cost of the raise will be thus reduced to $63.71 per foot.

The part of the shaft from the surface to a depth of 15 ft. was opened by sinking, so that the collar-set and three shaft-sets could be installed and concreted. With the raise finished to the surface, and the installation of temporary hoisting equipment, sinking was commenced at the 1000-ft. station, and a compartment 10 by 5 ft. 8 in. was sunk 200 ft., and this was temporarily timbered. After cutting a sump below the 1200-ft. station the lower 200 ft. of the shaft was enlarged to the size of the upper part by raising. A pump station is to be excavated at the 1200-ft. level, where two Prescott pumps of 600 gal. each, and one of 1200 gal. capacity are to be installed. The pump station will be protected by steel and concrete. The temporary head-frame of wood is soon to be replaced by a steel frame, 94 ft. high, the material for which is on the ground. Each of the two ore-hoisting compartments is to have a 100-cu. ft. skip, the two to be operated in balance. There are two 12-ft. sheave-wheels for the skips and one for the cage, the cable to be 1⅜ in. The power-plant, under construction, is 400 ft. southwest from the shaft, at a lower elevation. The engine house, 120 by 47 ft., to be of concrete and steel, is to contain one duplex, first-motion Corliss engine, 26 by 48-in. cylinder, for operating the skips; one geared hoist, 20 by 48 in. for operating the cage; both engines are of Allis-Chalmers make. An air-compressor of large capacity is to have a place in the engine room. The maximum depth to which the duplex hoist may operate is 2500 ft., its speed 1670 ft. per minute. The geared hoist is capable of operating to the same depth, speed 540 ft. per minute. The boiler house will consist of a steel building, 103 by 53 ft., and will contain eight horizontal return tubular boilers, which are on the ground ready for installation. The stack, to be built of radial brick, will be 150 ft. high, erected on a concrete foundation 21½ by 21½ ft., 9 ft. high. Close to the power plant is a wood-water tank, set upon a sub-structure of steel, to hold 25,000 gal. A new piece of equipment to be tried here in sinking is a Hulett grab-bucket for handling débris. The bucket, to be suspended from a skip, is designed to take up the rock from the bottom of the shaft, after the blast, then to be hoisted to the first station above, and there dumped into a loading pocket. Mr. Mills plans to experiment with it here as a possible means of more economical shaft sinking.

Exports from the United States to Canada show a larger growth in the current fiscal year than those to any other of the important countries of the world. For the ten months ended with April, for which the Bureau of Statistics has just prepared a detailed record of the commercial movements, the exports to Canada amount to $174,500,000, against $129,000,000 in the corresponding month of last year, and for the month of April alone, $22,000,000, against $15,000,000 in April of last year. The increase in exports for the ten months in question is thus $45,000,000, while the total increase in exports to all parts of the world during the same period is but $55,000,000, the figures in each case relating to exports of domestic merchandise. To France the export figures show for the period in question an increase of $9,000,000.

Prospecting and Testing of Clay Deposits

By E. K. Soper

Every geologist and mining engineer is well aware of the vast economic importance of the clay deposits of this country, and knows that there is hardly a State in the Union that does not contain valuable deposits. This importance may be better realized by a comparison of figures. In 1907 the value of the clay products produced by the United States alone for that year was $158,942,367, and was exceeded only by three other mineral products, pig iron, coal, and copper, while petroleum followed clay products with a value of $120,106,749. In prospecting for the metalliferous minerals these clay deposits are often overlooked, either because the prospector in his search for a mine is prone to pass by such unromantic material as clay, or else because of a failure to appreciate its possible value. In some regions it would be useless and foolish to attach much importance to an occurrence of clay, even though it be of good quality, but there are valuable clay deposits awaiting development in districts where they could be put to profitable use. Many clays are especially suited to some particular use, depending upon their characteristic properties and also to a large extent upon the location and the prevailing industry of the region.

Considering clays in a broader sense, there may be included deposits which have become consolidated so as to exhibit all of the properties of a shale. These shales when ground and mixed with water will often be found to possess as great a degree of plasticity as the soft unconsolidated clays and may be used in the manufacture of the same materials as could clays. In prospecting for clays, a knowledge of their methods of origin and the consequent shapes of the deposits, will be of much aid if borne in mind. Several classifications of clays have been made, some based upon their physical properties, and others upon their methods of origin. The following classification by H. Ries[1] is given and will be found, I think, to be of most value to the prospector.

A. Residual clays (by decomposition of rocks *in situ*). I. Kaolins or china clays (white burning). (*a*) Veins, derived from pegmatite; (*b*) blanket deposits, derived from extensive areas of igneous or metamorphic rocks; (*c*) pockets in limestone, as indianaite. II. Red-burning residuals, derived from different kinds of rock.

B. Alluvial clays, representing deposits formed by wash from the foregoing and of either refractory or non-refractory character.

C. Transported clays. I. Deposited in water; (*a*) marine clays or shales (deposits often of great extent), white-burning clays, ball clays, fire clays or shales, buff-burning, impure clays, or shales including both calcareous and non-calcareous; (*b*) lacustrine clays (deposited in lakes or swamps), fire clays or shales, impure clays or shales, red-burning calcareous clays, usually of surface character; (*c*) flood-plain clays, usually impure and sandy; (*d*) estuarine clays (deposited in estuaries), mostly impure and finely laminated. II. Glacial clays, found in the drift, and often stony; may be either red or cream burning. III. Wind formed deposits (some loess). IV. Chemical deposits (some flint-clays).

The third class of the transported clays is of little importance. The residual clays are found chiefly south of the southern margin of the ice-sheet of the glacial period and east of the Mississippi, especially in the Piedmont and Appalachian areas of the Southern States. There are, however, some valuable deposits of clays of this type in Wisconsin occupying areas which were protected from glacial erosion. The transported or sedimentary clays are widely distributed throughout the United States, but certain types occur oftener in some localities than in others. The most valuable of these in this country are the fire-clays, and in general it may be said that the distribution of the fire-clays in the United States will conform somewhat with the distribution of the coal deposits. It should not be inferred because a clay is found along, or close to a coal seam that it must be a fire-clay, although the term 'fire-clay' is widely used by miners to designate any clay found along the seam, regardless of the refractory properties, just as the term 'slate' is used by them when in truth it is often shale. On the other hand, fire-clays are not restricted in distribution to the coalfields. There are important deposits of fire-clay in Tertiary-Cretaceous formations in the Atlantic and Gulf coastal plains which are rarely associated with coal-beds. But the most important occurrences of fire-clay are found in the Carboniferous rocks. The geological and geographical distribution of the more important types of clays is shown briefly in the following table:

GEOLOGICAL AND GEOGRAPHICAL DISTRIBUTION OF CLAYS IN THE UNITED STATES

Fire clays	1. Carboniferous—Appalachians and Central States. 2. Cretaceous—New Jersey and West. 3. Tertiary—Pacific Coast, Missouri, Texas, and Mississippi.
Pottery clays	1. Kaolins or china clays—Georgia, South Carolina, North Carolina, Pennsylvania, and Delaware (older rocks). 2. Ball-clays (sedimentary) Tertiary—Kentucky, Tennessee, and Florida. 3. Stoneware clays: (a) Carboniferous—Appalachians and Central States; (b) Tertiary—In the West; Cretaceous also. 4. Earthenware clays—Found anywhere.
Vitrifiable clay (Sewer-pipe clay)	1. Devonian—In Eastern States. 2. Carboniferous—In Central States. 3. Cretaceous and Tertiary—In the West.
Brick and tile clays	Impure surface clays and shales. Very wide distribution geologically and geographically.

In prospecting, the outcrop is the most practical means of detecting a clay-bed, except in the case of fire-clays, which are often found only when mining operations have exposed the underlying strata. The

[1] 'Clays, Occurrence, Properties and Uses', H. Ries, 2nd ed., 1908, p. 27.

outcrops are oftenest found on steep inclined surfaces or in natural or artificial cuts, such as stream banks, railroad or wagon-road cuts, ditch lines, etc. Springs often indicate the presence of a clay-bed, especially if several springs issue from a hillside all along the same level. The clay, acting as an impervious stratum or dam diverts the downward moving water to the surface of the bank. In glacial drift, the presence of ponds is often indicative of clay beneath. Again, clay deposits are often found as the result of the weathering of certain rocks, such as granite, limestone, sandstone, etc. These residual clays are often characterized by their extreme irregularity in depth, and the prospector should bear this in mind when searching in such regions. Lastly, in some localities, clays produce vegetation of a different character from the growth on other soils, but this cannot be relied upon as a criterion.

Residual clays are apt to be irregular in depth, due to uneven weathering along joints and fissures in the original rock. Especially is this so in clays derived from crystalline rocks, and we would expect to find in such a deposit three principle zones: (*a*) a layer of fully formed clay; (*b*) clay of an impure nature with partly decomposed rock fragments; (*c*) a zone of many rock fragments (more or less decomposed) with some clay, grading into solid bedrock. Clay formed from limestone is an exception to this rule, for here the change from clay to hard rock will be sudden, due to the different manner in which the clay was formed. In granite the change from hard rock to residual clay is due to a gradual breaking down of the minerals in the original rock, while in limestone, solution is responsible for the transition. Hence it is important to determine the consistence of the deposit from top to bottom. An exceedingly irregular bottom may preclude steam-shovel work in mining operations. The form of the deposits will depend on the rock from which it was derived. Granites may yield great masses covering large areas, whereas pegmatites (feldspar and quartz) will yield comparatively narrow belts, which will follow the course of the original dike or vein. The depth of the deposit will depend upon the climatic conditions, the topography, and the parent rock.

All sedimentary clays present a stratified structure. Aside from this, however, different deposits may exhibit extreme irregularity of structure. Such a deposit may be consolidated into a hard shale; it may have had its surface greatly eroded and an entirely new material laid down on top of this; the deposit may be of irregular thickness; there may be 'pits' or 'chimneys' extending down and filling old depressions which will lead to false conclusions as to the extent of the bed. All of these possibilities should be guarded against before arriving at a definite conclusion regarding the value of the deposit.

Assuming that a deposit of clay has been found and proved to be of such a quality as to warrant further testing, what should be the method of procedure? The first facts to get at are its shape and extent. Next, an accurate knowledge of its texture and uniformity must be had. Clays are not often of absolutely uniform grade, but contain many impurities, such as concretions, gravel, and sand. If these are widespread and scattered it is a bad indication. If the impurities occur in streaks or layers it may be possible to avoid them in excavating. The character and thickness of the overburden is an important factor influencing the cost of extraction. If the bed is exposed across its entire thickness it should be carefully examined to note whether it is of uniform texture or whether it contains streaks or layers of sand or other injurious materials. The presence of gravel or pebbles is a common occurrence and is a great detraction from the value of the deposit if they occur in large quantity. If the clay is not exposed across its depth, holes should be bored through it at several points and the borings carefully preserved for samples. A post-hole auger, cutting a hole 3 or 4 in. diam. can easily be employed for this purpose to a depth of from 30 to 40 ft. Any variation in the texture at the surface and deeper down should be carefully noted. Some clays are much more plastic at the surface. Samples of about 50 to 75 lb. each should be taken from several points on the clay-bed and from the bore-holes, for testing in the laboratory. If large samples are desired for making tests on a working scale, pits should be dug at the points where the borings were made.

Having got the samples in the laboratory the problem is to determine to what use the clay can be most profitably put. Much has been written regarding the chemical analyses of clays, but for most purposes, and certainly for the purpose of determining the value of clay for making burned clay products, the chemical analysis is of little value. Only a careful consideration of the physical properties can determine the value of most clays. The most important tests to make are the following: (1) Water required to attain maximum plasticity, (2) the air shrinkage, (3) the fire shrinkage, (4) percentage of absorption after burning at different temperatures, (5) color after burning at different temperatures, (6) fusibility, (7) tensile strength, (8) plasticity. In some cases it may be desirable to make a mechanical analysis to determine the relative amounts and sizes of the constituent grains. Another test often made is to determine whether the clay will stand fast drying when freshly mixed, without warping or cracking. This is important where bricks are to be artificially dried as they are in the larger yards. Many clays will not stand rapid drying. Occasionally a few simple chemical tests may be desirable, as, for instance, getting the percentage of soluble salts present, or determining in clays to be used in the manufacture of portland cement the quantity of $CaCO_3$.

To determine the percentage of water required for mixing, a 5-lb. sample should be weighed out, dried, ground through a 40-mesh sieve, and enough water added, little by little, until the mass has attained its maximum plasticity. This cannot be determined absolutely, but with a little practice an approximation may be reached sufficiently close for all practical purposes. The plastic mass is next worked thoroughly to permit all lumps to slake down. This can be quickly done by kneading the mass like dough for a few minutes. When the clay is thoroughly mixed, eight or ten small bricklets are made in a

brass mold. A convenient size is 4 by 1 by ¾ in. A fine line is ruled along one side of each bricklet and two marks plaeed on this line exactly 3 in. apart, to be used in determining the shrinkage. The bricklets are then set aside in a warm place and allowed to stand until thoroughly dry. This will usually require four or five days in the ordinary temperature of the laboratory. They are then placed on a hot-air bath and heated to about 100°C. to drive off the remaining moisture. The bricklets are then measured and the air shrinkage is expressed in percentage of the original measurements. After burning the bricklets the fire shrinkage is found by subtracting the air shrinkage from the total shrinkage.

For laboratory work a variety of kilns or furnaces are used. Some gas furnaces, such as the Segar furnace, when slowly fired and properly handled give excellent results. Certain oil kilns are now also much used, but cannot reach as high a temperature as the Segar furnaee. This gas furnace is circular in form, and the gas enters through six or eight burners and passes upward through a small slit near the bottom. The air is pre-heated and as it comes from below unites with the gas at the burners. Inside the furnaee is placed a cylinder and in this cylinder a crucible in which the tests are confined. The mixture of air and gas passes between the wall of the furnace and the fire bridge, over the cylinder and then downward between it and the crucible.[2]

The absorption is determined simply by getting the difference in weight between the dry and saturated bricklet. This is commonly expressed in terms of the original dry weight. After each burning at a different temperature any variation in the color of the clay should be carefully noted. The color of the raw or unburned clay does not always indicate the color of the burned product. Red clays usually burn red; deep yellow clays may burn either buff or red; chocolate ones often become reddish brown; white clays will usually remain white, but may turn yellowish; and gray or black ones may turn almost any color, but commonly red, buff, or white. Calcareous clays may burn red at first but turn cream or yellowish as the vitrifying temperature is approached. Alumina present in excess has a bleaching effect similar to lime. When clays rich in iron are burned to vitrification, greens, browns, and blacks are often obtained.

The most convenient method of measuring the temperature of the kiln during burning is by means of Seger cones, which are mixtures of clays with fluxes, so graded that they represent a series of fusion points, each of which is a few degrees higher than the preeeding. They are classified by number and the fusion point of each number is given. They range from cone 022 (590°C.) to cone 39 (1940°C.), advancing by intervals of about 20° each. These cones are not only used in testing in the laboratory, but many of the large plants manufacturing burned clay wares of all kinds employ them in controlling the temperature of the kilns.

The tensile strength of a clay is determined in the same way as that of a cement. Small briquettes are molded, each being 1 in. in eross-section at the waist. These are thoroughly dried and tested to failure in a tension testing machine of the usual type. Care must be taken to correct the results for shrinkage of the cross-section of the briquette upon drying.

The question will doubtless be raised as to how these laboratory results compare with the results of practice on a large scale. In general they are very close. Some deviations, however, should be admitted. The air shrinkage in the laboratory is sometimes higher than in the factory on account of the better mixing facilities at the latter place. This is an error on the side of safety. In the case of very sandy clays the error, if any, will be the other way. In practice, brighter colors are apt to be obtained on burning than in the laboratory, because firing in a large kiln is slower, which gives the iron in the clay a better chance to oxidize. This is especially true during cooling. Slow cooling tends toward brighter colors. To minimize this error, do not stop the kiln suddenly when the fusion point of the test cone has been reached. The application of this principle is seen in the burning of pure white chinaware. The iron is counteracted by adding cobalt, which gives a bluish tint. The kiln is also cooled as rapidly as possible to prevent any further oxidation of the iron.

Clay for common brick must burn to a fairly hard body with a good 'ring' at about cone 010 (950°C.), or even less. It should burn rather dense with an absorption of not more than 15%. The color of the brick is not important, but red-burning clays are preferable. Cream-burning calcareous clays are good, but there is danger of not getting to a dense body at cone 010 unless the clay is very plastic. The method by which bricks are to be manufactured is important in the choice of a clay, or, stated in the opposite manner, the character of the clay will largely determine the method which must be employed. Any clay will work for the 'soft-mud' process, but the 'stiff-mud' process requires a clay of medium plasticity. The tensile strength should be around 100 lb. per square inch, but a clay with a tensile strength as low as 60 is often used with success. If artificial heat is to be used in drying, the clay must not crack when dried rapidly. If it does, this may be overcome by mixing with it 25% of sand. The air shrinkage should be from 3 to 5%. The fire shrinkage should be low, but it is desirable to have a little fire shrinkage, since this gives the brick a denser and harder body. For drain-tile the same class of clay may be used as for common brick, but it should be smooth and plastic. Sandy clay is undesirable. Earthenware, flower-pots, and similar products require a clay that is smooth and of good plasticity. The tensile strength should be 100-125 lb. per square inch. The clay should burn moderately hard and dense at temperatures from 950 to 1050°C., with an absorption of 14 to 15%. It should have a low air and fire shrinkage to prevent warping in burning. The color is not important, but red is commonly used. Stoneware clay must be of a better grade than the foregoing. It is often molded on the potter's wheel, so it should have a high plas-

[2]For a complete description of this furnace, with sectional views, see 'A Report on the Clays of Maryland,' by H. Ries. Maryland Geol. Surv., 1902, p. 284.

ticity and good tensile strength of not less than 125 lb. per square inch. The combined air and fire shrinkage should not be less than 12%. Stoneware is commonly burned at temperatures ranging from 1230 to 1250°C. The clay must burn to a tight, dense, impervious body at 1250°C., and it should be fairly refractory, not fusing under cone 27 (1670°C. or 3038°F.). Since it is not common to find a clay that exhibits all of these requirements, mixtures are usually made in the factories of two or more clays to get the proper qualities.

Fire brick requires a very refractory clay which is burned to about 1310°C. (2390°F.). High plasticity is not required in fire clays, only sufficient being necessary to permit molding. The air and fire shrinkage should be low and the clay should burn fairly hard, but without vitrifying. The tensile strength should be higher than for common brick. Fire-clays are among the most valuable of all clays, and many factories employ mixtures to obtain the required properties. In fact, few fire bricks are made from one kind of clay, but are usually mixed with 'grog' (ground brick). Grog reduces the shrinkage if it is too high. In order to test the fusibility of fire-clays a special furnace will be required. The Deville[3] furnace is widely used. This is constructed of a hollow fire-brick vertical cylinder encased in a cast-iron shell, over which a bell-shaped chimney is hung like that of a blacksmith's forge. A small blower forces air through the chimney. The clay to be tested is enclosed in a small fire-clay crucible and placed on a base at the bottom of the hollow fire-clay cylinder and the cylinder is then filled up with coke, completely covering the crucible containing the clay. The principal disadvantage of this furnace is the fact that the test-piece cannot be watched and the temperature reached must be determined by placing in with the clay several cones which fuse at different temperatures. By observing the cone which remained unaffected by the heat and the cone which melted last, a close approximation can be made of the temperature reached.

Paving brick are usually made by the stiff-mud process, and therefore require a clay or shale of not too high plasticity and one which will vitrify at cone 2 to 3 (about 1119°C.). It is desirable to have the tensile strength greater than 100 lb. per square inch, but not necessary. A low air and fire shrinkage is required. Sewer pipe requires the same clay as is used for paving brick, but a low-grade fire-clay is often added. Porcelain and white granite-ware take a clay that burns snow white and stands a high degree of heat. Kaolins and ball-clays mixed with quartz and feldspar are used. Owing to the high refractory nature of kaolins they burn to a porous body and are low in tensile strength and plasticity. Ball-clays supply what kaolins lack, hence all potters use a mixture of ball-clay and kaolin. There are a few clays which melt to a natural enamel or glass at a temperature of about 1250°C. These are especially valuable as 'slip clays' and are used for natural glazes on other clay products, such as decorative tiling and facing brick.

[3]See 'A Report on the Clays of Maryland', H. Ries. Maryland Geol. Surv., 1902, p. 284.

In recent years the manufacture of portland cement in this country has undergone such rapid and wonderful development that a new and extensive field has been opened for the development of clay deposits. Portland cement is made from one of the following mixtures: clay and limestone, limestone and shale, marl and clay, chalk and clay, pure limestone and argillaceous limestone, alkali waste and clay, and limestone and slag. Out of these seven possible combinations it is seen at once that clay is an important constituent in all but two. The final mixture from which the portland cement is made consists of about 75% lime carbonate and 25% clay. Clays for use in portland cement should be as free as possible from sand, gravel, and concretions. Usually silicious clays are used, the silica ranging as high as 70%, but calcareous clays are often employed in which the silica content falls far under 50%. In testing clay for this purpose the chemical analyses will be of use in many cases.

There are many other uses of clays and much has been written on the methods of preparing the raw material for the manufacture of these various clay products and upon the subject of ceramics in general.[4] Summing up, it is seen that the geological examination of clay deposits should embrace not only a thorough inspection of conditions in the field, but should be supplemented by a series of careful tests in the laboratory. These are chiefly of a physical nature, but chemical analyses should be employed where required. Ores are not bought upon an inspection of their structural features alone, but only after careful assays and mill tests have been made. So, clays, which may vary as much in grade and value as ores, should be put to practical tests before money and energy are expended on their exploitation.

[4]See 'A Bibliography of Clays and the Ceramic Arts', J. C. Branner. Published by Am. Ceramic Soc., 1906.

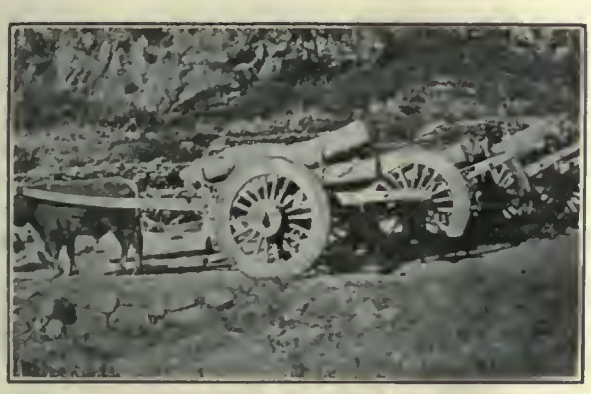
Argentina, in its Andean provinces, is known to be rich in minerals. R. M. Bartleman, United States Consul at Buenos Aires, reports that gold, silver, lead, copper, iron, tin, zinc, and antimony are found at various places in the territory of Los Andes. The ore in La Concordia group of mines contains, on an average, 2.62% of copper, 12% of lead, and 2034 gr. of silver to the ton. The mineral of the Recuerdo mines, a mile from the Concordia, has given 33 to 41 grains of gold and 635 to 1679 of silver per ton, besides lead, iron, copper, tin, zinc, and antimony. The borate of lime mines in Los Andes have not yet been worked. During 1908 a gold mine company obtained $16,234 worth of gold from 5690 tons of ore in the Nilla Michi-Co and Malal Caballo district. A limestone quarry was worked in 1908 in the Rio Negro territory, and numerous concessions for salt mines were granted in the Territory of Santa Cruz. The auriferous sands of Tierra del Fuego are being worked, but by primitive methods. Copper ore has been discovered in Missiones territory, for the working of which applications have been made. The completion of the railway to Posadas, together with the good river communication of this territory, will greatly assist in marketing this copper.

Dredging Possibilities in Korea

By R. Y. Hanlon

Korea today affords one of the most promising fields for mining capital to exploit. Not only is this true in regard to copper and gold in veins, but especially as regards placers, which cover immense areas throughout the country from Masanpo in the south to Mantaikol in the north. It is with the placers entirely that this article will deal.

Korea is a peninsula some 600 miles long, situated between latitudes 35 and 42 north, and stretching down into the Yellow Sea from the southern boundary of Siberia and the eastern boundary of Manchuria. It enjoys a climate very similar to that found in the Middle Atlantic States of America. The



Ancient Transportation—Hauling Mine Timbers.

inception of placer mining in the country is lost in antiquity. Hundreds of years before Japan acquired a protectorate over the country, the Koreans paid to China large sums annually as a tribute, practically all of which was won from the placers. I have had

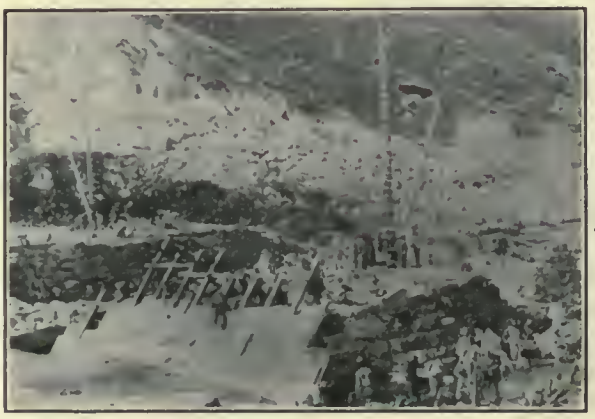
Electric Power Plant, Unsan Gold Mines.

occasion during the past four years to examine five large deposits in widely separated parts of the country, and while not at liberty to make public all of the data acquired during these examinations, can give an account of the physical characteristics of the deposits and other material which may prove of interest.

The Oriental Consolidated Mining Co. controls a concession which covers about 30 lineal miles of river bottom land ranging in width from 500 to 3000 ft. They have had this ground prospected with a Keystone No. 3 traction drill to the extent of some 300 holes, covering an area of about 1500 acres, and although the average gold content in the deposit, as shown by the above work, is not high, it is not inferior to that contained in a large part of the California deposits which are being worked today at a good profit by 8½ and 13½ cu. ft. dredges. The ground is a loose wash, contains no clay or large boulders, and overlies a soft, fairly level, decom-

Modern Transportation—Wood Road of Oriental Con.

posed granite or schist bedrock—principally granite. The average depth from surface to bedrock is about 18 ft., and the natural water-level stands at about 5 ft. below the surface. All Korean placer deposits are cleared land, often agricultural, and when such



Constructing a Dam in Korea.

is the case they must be purchased from the owners at a price ranging from $18 to $30 per acre.

In the southern part of the country, 60 miles south of Seoul, the capital, and 300 miles south of the Oriental Consolidated concession at Unsan, is situated the Chicksan concession controlled by an American-Japanese syndicate—the Korean Exploration Co. and the Shibusawa-Asano Mining Partnership. This concession covers about 400 square miles, and contains within its boundaries many excellent veins and an immense area of alluvial deposit, of which only about 1000 acres has been prospected. The ground is about 20 ft. deep, and has a topping of soil and clay ranging in thickness from 5 to 9 ft., overlying 8 ft. of barren gravel, and from 3 to 7 ft. of pay-gravel. The clay is tough and stands up easily in a bank, the natives in their operations are in the habit of undercutting it from 5 to 8 ft. and prying it off in large sections from the surface. They use for this purpose long iron-shod poles. This deposit contains about 60% sand and the gravel is so fine that little

or no drilling is necessary when prospecting with a 5-in. (inside diameter) pipe. The bedrock is a soft decomposed biotite rock somewhat sticky, but easily washed.

The natural water-level is usually on the line of demarkation, between the clay and gravel, the change between these being abrupt. This concession is ideally situated as regards transportation and enjoys a climate more equable than that of the northern part of the country. The Imperial railway passes through the concession, and within five miles of the principal placer fields. In addition to this, there is a good bay 15 miles away at which coal of good calorific power may be delivered at a cost not exceeding $5 per ton.

Transportation facilities throughout Korea, with the exception of parts of the east coast and the extreme north, are good. The railway passes nearly through the centre of the peninsula for a long distance, and directly through the principal mineralized zone in Pyeng Yang Do province. All of the properties now under exploration in the country, with the exception of the copper concessions at Kangai and Kapsan, are within 75 miles of the railway or near some port upon the east coast. In addition to this nearly all of the rivers upon which any placers are located are navigable for three to six months of the year, and furnish a cheap method of transportation by means of native junks or flat boats. Parts of the country north of Pyeng Yang are heavily timbered, oak and pine predominating, and afford fairly good fuel at $2 to $3 per cord. In the south, however, it is necessary either to transport the wood long distances or to use coal or oil. Upon the completion of the railway between Wijos and Moukden, Manchuria, it will be possible to procure an excellent grade of coal for $3 to $5 per ton delivered upon the ground. The price, of course, will depend to a great extent upon the accessibility of the property. The Oriental Consolidated is operating a 500-kw. plant, generated from a stream, about five miles from the main camp. It was necessary to build a dam some 300 ft. long and 80 ft. high in order to form a reservoir large enough to warrant the installation. There are many streams in the mountains which are capable of generating large power, but as yet they are entirely undeveloped.

The climatic conditions, although by no means ideal, offer no serious difficulties to dredging. During the months of July and August heavy rains prevail. The precipitation during these months has averaged about 20 inches for the past eight years, as against an average annual fall of about 42 inches, but owing to the flatness of the country and the great width of the principal river beds and valleys, these heavy rains seldom do any damage. The winters in northern Korea are quite severe, but of short duration—from January until the middle of March. The average temperature in January and February for the years 1907 and 1908, at Pyeng Yang, in latitude 39°N., was 29.5°F., and in latitude 36°N. only 37°F. Dredging is now being carried on near the mouth of the Amur in Siberia even farther north.

Many of these Korean placers have a topping of from 4 to 8 ft. of soil and clay over several feet of barren gravel, and from 2 to 5 ft. of pay-gravel. Today there are about ten of these deposits, ranging in area from 100 to 3000 acres, and scattered throughout the country, being worked by antiquated methods and yielding in the neighborhood of $1,500,000 in gold per annum. The Koreans handle about 1½ cu. yd. per diem for every man employed upon the work and upon this basis one is safe in assuming that they cannot work and gain a living from gravel averaging less than 8c. per cubic yard, actual extraction. Tests which I made of ground covered by some of their operations showed that their actual extraction has been less than 70%, and in many instances less than 60%. The lower extraction was made usually in gravel through which the gold was quite evenly disseminated, and a large part of which ground they had discarded with the overburden. By their system of passing the pay-gravel over short lengths of riffles placed at a pitch of 3 to 5 in. to the foot, they invariably lose nearly all of the fine gold. This forms no inconsiderable part of the total, and nearly all could and would be saved by a modern gold dredge.

As yet there are no dredges operating in the country but several companies are considering installations and it is only a matter of a short time until several of the most promising and better known fields may be expected to be producing and paying good dividends upon the capital invested.

TUNNELING UNDER AIR PRESSURE

There is considerable difference between horizontal and vertical excavation. In vertical work there are no overlying strata. In the case of the tunnel the weight of material overhead becomes a very serious factor indeed. An air tension equal to the hydraulic pressure will keep the water out from every direction. But the solid material overhead may, under exceptional circumstances, be pressed down by a pressure comparable with its actual weight. This is about two and one-half times that of water. Under ordinary conditions the overlying strata are self-supporting a short distance above a tunnel. Between the lowest point of self-support and the roof of the tunnel lies material whose fall is to be expected. The air pressure, whether great or small, cannot be relied on to support this. The reason for this circumstance is the porosity of the soil. If the compressed air could not penetrate the earth and get above it and the imbedded boulders, then the air pressure might be expected, ordinarily, to assist in keeping the roof intact. But with the air pressure above and below its particles the same, the material will fall under the influence of gravitation. It is necessary, then, to provide an air pressure to withstand hydraulic thrusts and a mechanical support to oppose the weight of overlying loose material. To meet the conditions outlined the usual modern practice in subaqueous tunneling is to operate a device known as a shield, to support the roof permanently to the rear of the shield and temporarily in advance of it, and to carry out the excavation and introduction of supports under pneumatic pressure.—*Cassier's Magazine.*

Genesis of Ores

From the MINING AND SCIENTIFIC PRESS, January 24, 1871
By JOSEPH LECONTE

The true theory of ore genesis, in my opinion, has been touched on in some of its relations in published works, but has not been made public in its entirety heretofore. It is this: That the fissures were filled by deposits from *hot alkaline solutions* circulating through them, even from the greatest depths. It is proposed now to show that the veins were filled: (1) from solutions; (2) from hot solutions, and (3) from hot alkaline solutions.

1. From solutions.—The peculiar ribbon structure is as characteristic of mineral vein matter as the columnar structure is of basalt. This point tells very strongly against the fire theories and for the water theory. From the same cause we find the same structure in veins of infiltration. Again, the most common of all vein-stones is quartz, which occurs nine times out of ten; yes, ninety-nine times out of a hundred. Now there are two kinds of quartz. One has a specific gravity of 2.8, the other a specific gravity of 2.1 to 2.2. The first is formed only by deposition from solution, the second only on cooling after fusion. The first is found invariably in metallic veins, while the second is never found there. There are many other contents of mineral veins which cannot possibly be formed by fire, but only by water. These are the minerals containing water, the hydrates. In vein-stones, we very often find fluid cavities. In rocks formed by aqueous action, any such cavities contain water, while in those formed by the action of fire, the cavities contain only air. Vein-quartz and all vein-stuff, have the fluid-cavities.

2. From hot solutions.—A fissure reaching downwards is always filled with percolating waters. Now as our mineral veins extend down a great distance, these waters must be hot. The solvent power of hot (super-heated) water is well known. It dissolves many substances generally considered insoluble. In the case, referred to above, of cavities filled with a fluid, if these were filled while hot and then cooled, as the containing crystals cannot give and the fluid contracts on getting cold, a vacuous space is left which presents the appearance of a bubble. This last we find a common occurrence. If we put such a crystal with such a cavity under the microscope, and apply heat, we can determine the temperature at which the crystal was formed; for on reaching this temperature, the fluid will have expanded to its original volume and will exactly fill the cavity, the bubble then disappearing. This fact opens a field of research of the greatest importance and interest. In this way it has been found that actual deposits have been formed at 150°, 212°, 250°, up to 400°, 600°, 800°, and 1000°. Now quartz and other vein-stuff have such cavities which have been shown to have been formed at 180° to 212° and even 300° and 400°. It may be remarked that such cavities occur often in crystals, when, on account of the imperfect transparency or opacity of the material, they are not apparent.

3. From hot alkaline solutions.—We need a powerful solvent to get our vein-matter in solution. Our hot water probably is not sufficiently powerful. We find it in nature in an alkali,—a carbonate, particularly carbonate of soda. Alkaline waters and springs are known everywhere, and are especially frequent on our coast. Quartz is one of the most insoluble substances known. Only a few substances will dissolve it. Its natural solvents are alkalies. In making artificial stone this fact is taken advantage of. Again, as the metal is enclosed in the quartz, we must believe that it was deposited from the same solution. It has been shown before that most metallic minerals occur in nature originally as sulphides. Now alkaline sulphides will dissolve metallic sulphides. These alkaline sulphides are abundant in California and elsewhere. Most of the sulphuretted-hydrogen springs derive their sulphur from these sulphides, this combining with the hydrogen. More probably, however, the metals were in solution as sulphates, many of which are easily soluble. These coming in contact with organic matter (so common in nature), were then reduced to sulphides. Such reactions are occurring all the time under our eyes.

A study of the veins of California and the hot springs of this State and Nevada, has done much to put this theory on a solid foundation. Thus, the fact that gold, the most insoluble of all metals, is dissolved only in free chlorine, which doesn't exist in nature, has been the great stumbling block hitherto to the theory of solution. But the explanation of this can be found by examining the deposits on our coast. The gold mines of California (and all gold mines) are of two kinds—quartz and placer. The first are on true auriferous veins, where the vein-stuff is invariably and almost entirely quartz. The minerals contained are sulphides of iron, lead, zinc, and copper, and perhaps quicksilver. The most common is sulphide of iron, and the gold occurs always in connection with iron pyrites. If we take sulphide of iron, gold-bearing pyrites, and dissolve it in nitric acid, we find the gold left untouched in the original state, and as little threads and crystals. It was then deposited from a solution. Now, in an ordinary quartz vein, the effect produced by us with the acid has been produced by the meteoric agencies of nature, and the gold is found at the surface in the same shape. The quartz vein is denuded and the placer mines are formed, in which we find rounded blocks and boulders and rounded nuggets as evidences thereof.

We have two kinds of placers—the deep and the superficial. The deep placers were formed in the beds of ancient rivers, as they existed many years ago. Then streams of lava poured down from the Sierras, and these naturally flowed into and along the river channels, covering the gold deposits and dispossessing the waters of their beds. The waters were forced to run elsewhere, and formed what are the present superficial deposits. We find in the deep placers certain phenomena which advance our theory. We frequently find gravels cemented with silica, and we also find wood silicified. These circumstances were induced by soluble silicates, and

point to alkaline waters. Again, we find often gravels cemented with iron pyrites, and wood petrified with this material. Waters, holding sulphate of iron in solution, percolated through the drifts, and meeting the wood or other organic matter, deposited sulphide of iron. If we dissolve this sulphide of iron in nitric acid, we find the contained gold sometimes in the form of rounded granules. In this case, it was washed here, and then the sulphide formed around it. But we also find it as fine threads and crystals, as in veins, and, therefore, it was deposited from the same solution as the enclosing sulphide. We are thus almost driven to the conclusion that the solvent was a solution of sulphate of iron. We enquire then—will this dissolve gold? We must remember in this connection the difference between the operations of the chemist and those of nature. The chemist calls a substance insoluble, if it is not dissolved to any considerable extent in a limited space of time. But nature has the infinite ages of geological time to work in. Hence, a substance dissolved only in very small part by the chemist, may be entirely dissolved by nature. Now, gold is soluble to a limited extent in solutions of salts of iron, mostly in chloride of iron, but to a smaller degree in the sulphate.

The action then is this: The alkaline and percolating waters dissolve the quartz, which is afterwards deposited in its present position. The sulphate of iron held in the waters dissolves the gold, and when organic matter is met, the sulphate is reduced to sulphide and, as such, is deposited with the gold. This whole process is now going on, and we have a good example of it in the well-known 'Steamboat Springs' of Washoe county, Nevada. Here, through fissures, some being 2000 ft. long, boiling alkaline waters issue from the earth. These waters holding carbonate of soda, contain in solution silica which is deposited all around. The process of vein formation is going on here, and we can trace every stage of gradation. Some of the fissures are merely lined on each side with the deposits, some are nearly closed the same way, and some are quite filled (no further water issuing from them consequently) and are just like our known mineral veins. Here, too, are found iron sulphide and other metallic sulphides just as in a quartz vein, and it has been stated by a man of considerable scientific attainments, Mr. Lauer, that he has *found gold in the pyrites* here. This lacks further confirmation, but is still worthy of attention.

Some may ask, in this connection, where the iron sulphate comes from. We cannot go back to the origin of everything. We can only say that the sulphate comes from the sulphide and the sulphide from the sulphate, under oxidizing and reducing agencies. And where does the alkali come from? From the soda granites of the Sierras. The soda granite is that granite which contains soda feldspar. Soda granite is easily decomposed. In decomposition, the soda is changed to carbonate of soda, of which we have had so much to say. The waters leach out the soda carbonate (in small quantities at a time) and (for example) run into a lake. Many lakes, as Mono and Owens, having no outlet, their waters are concentrated by evaporation. The distilled water falls again on the granite, takes up more alkali and runs into the lake again, and in this way we in time get bodies of strong alkaline water. There was a time when California was more volcanic than it is now; when hot springs, carbonate alkali springs, were almost everywhere; and thus the vein formation could have been carried on to a large extent, just as we see it done now in the present example. I believe that this idea is the foundation of the true theory of the formation of veins. It may be, probably will be, modified and perfected as our knowledge increases, but the essential portion will remain.

LOS ANGELES MEETING OF THE AMERICAN MINING CONGRESS

The 1910 convention, which is the thirteenth annual, is to be held at Los Angeles, California, September 26 to October 1. Sidney Norman, secretary of the Los Angeles branch, has been named as director of local arrangements and is at the head of the Los Angeles committee. There will be nothing lacking in the local preparations to make this meeting a great and memorable one, and all members and delegates who attend will have good reason to remember the hospitality and welcome of the mining and business men of this metropolis of the Southwest. The consent of all railroads to a round-trip rate of one and a third fares from all points, for the meeting has already been secured, and even some concessions from this rate are expected. Excursions, arranged so as not to conflict with the program of the convention, will be run to the oilfields in the Bakersfield district, and to some of the mining districts of Arizona. An excursion to the Catalina Islands will be arranged for the wives and lady friends of the delegates. The official call will shortly be issued.

Direct communication between New York and the West Coast is announced by the Woermann Line, which is about to operate on a new steamship route. The first steamer, the *Otavi*, will leave New York on July 25, 1910, with a monthly sailing thereafter, touching at Las Palmas and Teneriffe in Canary Islands, Secondi, Accra, Lagos, Calabar, Duala (Camaroon), and at intermediate ports, providing freights are offered. On the return voyage mineral ores will be taken from German Southwest Africa to the United States, the vessels coaling at Las Palmas. Freight on return voyages to the United States will not be accepted. A few passengers to these islands and other ports on the West Coast of Africa will be accepted, some steamers having accommodation for about ten.

Metavanadic acid has been used to some extent as a substitute for gold bronze in paint. Vanadium chloride is used as a mordant in printing fabrics, and the trioxide as a mordant in dyeing. Vanadic anhydride (V_2O_5) has been used in the reduction of various organic compounds in an acid bath, for example, the manufacture of quinine from aniline. It also greatly accelerates certain oxidation processes, such as the action of nitric acid on sugar or the oxidation of alcohol by atmospheric oxygen.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Pay sand varies greatly in thickness in the various oilfields. In West Virginia, I. C. White considers 5 ft. to be a safe estimate in good territory, and D. T. Day gives the same figure for Pennsylvania. In Illinois the pay sands vary from 2 to 30 ft. in thickness. At Spindle Top, in Texas, the average was 75 ft. In California, particularly in the Kern River field, thicknesses of 100 ft. have been found.

Edison's new storage battery car itself weighs about one-half as much as an ordinary car, or about 10,000 pounds. Its carrying capacity is two tons. One of the greatest savings in weight is in the building of the roof, which, not having to carry the weight of a trolley pole, is only 10% as heavy as one that does, so it is made out of a thin wood veneer. The vestibule doors are omitted and the car is made as light as possible throughout.

Sandstones change by the action of intense pressure into quartzite, a hard, compact, granular material composed of adherent quartz grains which have been re-crystallized, so that the rock breaks with a characteristic lustrous fracture. The production of most quartzites has, however, been aided by the infiltration of silica in solution into quartz-sand, and its deposition upon the quartz grains so as to bind the rock into a mass almost as compact as vein-quartz.

Vanadium finds by far its most important use in steel. Remarkable claims are made for the toughness imparted through the use of small quantities of it. This effect is said to be due to its removing oxygen and nitrogen, to its forming a solid solution with the iron, and to its forming carbides which have a beneficial effect. It is claimed that after treatment with vanadium, steel has great resistance to shock and fatigue caused by constant bending; that it makes better saws and springs; and that high-carbon vanadium steels also make better tools, such as cutters and riveting dies.

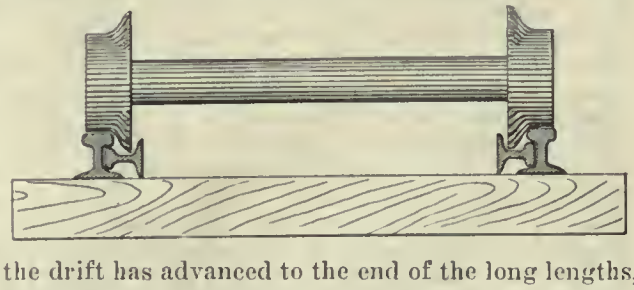
A close-connected bucket dredge operating on Shoalhaven river, New South Wales, showed at a recent clean-up, after 20 days' work that 88% of the gold was caught before it traveled 20 ft., 8% 50 ft., 4% was taken off the mats of the last 30 ft. of boxes, and only a few pennyweights went to within a few feet of the end. The dredge is now running 18 buckets per minute, but when an increase in the pumping capacity of from 3000 gal. to 4500 gal. per minute has been arranged, it is hoped to run 20 or more to the minute, and get the costs down to 1d. per yard.

Dry rot, which affects mine timber is due to the growth of a fungus of which the fruit presents the appearance of irregularly shaped, flattened, or undulating patches of variable size, adhering by their entire under-surface to the substance on which they are growing. When mature the central portion of the patch is covered with an irregular network formed by slightly raised anastomosing ribs, and is of a rich brown color due to the enormous quantity of spores which are deposited on surrounding objects under the form of snuff-colored powder. These spores are diffused by currents of air, or by rats, mice, and insects.

Powder headache is due to breathing poisonous gas resulting from the explosion of the powder. The best cure is to get into the fresh air and the best preventive is to secure adequate ventilation. When a man is overcome by powder smoke he should be carried promptly into fresh air and if necessary artificial breathing should be induced as in cases of drowning. When it is available, oxygen may be administered to advantage. It is worth remembering that a man once overcome by gas is for a long time subsequently peculiarily susceptible to its influence. Such a person may be seriously affected by an amount of gas that is not noticed by others.

High cost of living, according to B. F. Yoakum, is largely due to the middlemen. He presents the following interesting examples of how costs grow on the journey from producer to consumer: The Florida farmer receives $2.25 for a bushel of green beans, the railroad gets 50c. for the 800-mile haul to New York, and the consumer pays $6.40 for this same bushel of beans. There is 35% for the grower, 8 for the carrier, and 57 for the dealer. This is not a fair division. Thirty cents a dozen was the average price of eggs in New York last year, while the farmers of Arkansas and Missouri received 15c. The freight was 2c. per dozen. The men who receive the eggs at the station in New York and deliver them to the consumer take 13c. profit. The rice farmer of Texas, Louisiana, and Arkansas gets 2½c. per lb. New York pays 10c. for this rice. The freight is ½c. If the rice farmer were paid 3½c. (1c. more than he is now getting), and the dealer took 1c. profit (which is 25%) the New York consumer would get 20 lb. of rice for a dollar, instead of 10 lb. as now.

Temporary track may be laid easily and quickly by the following method, described to us by Elton J. Simmonds. Lay permanent ties as you advance. Take two full length T rails and lay them on their sides or edge just inside the permanent track so that the flange of the wheels runs in the groove of the rails, as shown in the accompanying figure. When



the drift has advanced to the end of the long lengths, turn them over on their proper base and spike. This method obviates short lengths, false rails spiked to ties, and other devices, and entails no unnecessary labor; not even an extra spike driven, as the long lengths have sufficient weight and bearing to steady themselves.

Special Correspondence

LONDON

Great Boulder Perseverance at Kalgoorlie. — Crown Mines and Ferreira at Johannesburg.—Frontenac Consolidated of Gilpin County, Colorado.

The Great Boulder Perseverance is one of the most interesting mines in Kalgoorlie, though not now of high grade. In its earlier years it produced rich ore, but in 1905 the reserve was found to have been exaggerated, and the control and management passed from the hands of F. L. Gardner and Ralph Nichols to others. Hooper & Speak were appointed consulting engineers and subsequently general managers, their Australian partner, Ernest Williams, assuming local responsibility. Under their direction extensive prospecting and development revealed the presence of orebodies averaging 7 dwt., and under the new conditions the company has continued to make profits. One of the last acts of the old management was to expand the nominal capital to £1,500,000, and on this exaggerated figure the present rate of dividends looks small, though on the original capitalization of £175,000 it would have been handsome. The company had a bad stroke of luck last year in the form of an outbreak of fire in the grinding and adjacent departments. This fire occurred on November 19, and destroyed the Griffin mills, the main driving engine, two air-compressors, electrical plant, and part of the boiler-house, roasting furnaces, and belt-conveyor. A sum of £22,340 has been recovered from the insurance companies, but the total cost of renewals will be over £40,000. Milling operations have been suspended and cannot be resumed until the new plant is ready for work in July next. In the meantime development has been prosecuted actively; 11,395 ft. of work was done in 1909, as compared with 7699 ft. in 1908. The ore reserve on December 31 was estimated at 380,772 tons averaging 6½ dwt., and there was also 249,080 tons in the mine averaging 4.94 dwt. classed as probably profitable. Other bodies of ore are known to exist, but as their content is not sufficiently investigated they are not included in the estimate. The main shaft is down to 2074 ft. During the year 1909, that is, from January 1 to November 10, the tonnage treated was 192,178, and the production was 70,681 oz. gold and 7829 oz. silver, with a total value of £300,949. The working cost was £185,422 and expenditure on development £40,263. The disposable balance of profit for the year was £56,837. The directors have decided to write off as lost the loan of £46,938 which F. L. Gardner as director and controller lent to himself personally in years gone by. It may seem remarkable that a director should be able to draw on his company to this extent, but in justice to Mr. Gardner it must be remembered that in early days when the sulpho-telluride ore caused such difficulties he spent out of his own pocket and without recompense more than this sum of money for the purpose of putting the company into a paying condition. After writing off this amount as lost, the profit for the year is reduced to £9899. In order to equalize dividends the sum of £50,000 has been taken from reserves and a dividend of 2½%, absorbing £34,986, has been paid. It had been intended to pay double this rate for the year, but the fire in November rendered this impossible. The treatment at this mine differs from that usual at Kalgoorlie. The ore is first crushed to the finest slime, then roasted, sent to amalgamating pans, and finally to cyanide plant and filter presses. In the destroyed plant, the comminution was done in Griffin mills, but in the new plant these are to be replaced by Krupp ball-mills and tube-mills.

The mines in South Africa have been attracting much attention recently owing to the various consolidations. One of the most interesting is the Crown Mines, which was formed on July 1 of last year as a consolidation of Crown Reef, Crown Deep, Langlaagte Deep, Robinson Central Deep, and Langlaagte Royal, all dividend-payers, Paarl Central, a producer not yet paying a dividend, together with other properties on the dip not yet developed. The control is with the Wernher-Beit group, G. E. Webber is consulting engineer, and R. C. Warriner is general manager. The company is in law a continuation of the Crown Deep company, so that the present report for the year 1909 is a composite one, covering as to the first half year the doings of the Crown Deep mine, and as to the second half the operations of the new company. As regards the second half of the year, the report shows that 740,924 tons of ore was treated by 675 stamps. The yield was 8.128 dwt. per ton or 34s. 1d., and the working expenditure was 17s. per ton, leaving a profit of 17s. 1d. The total working profit was £634,084, and £611,068 was distributed as dividend for the half year, being at the rate of 130% per annum. The reserve of developed ore on December 31 was 3,916,593 tons with an average content of 7.7 dwt. This figure does not show a great increase, a fact accounted for by the nature of the development during the half-year, attention having been concentrated on the preparation of the consolidated properties for the new system of exploitation rather than to the extension of the ore reserves. Five new tube-mills and additional cyanide plant have been provided, and the monthly output will be increased to 157,000 tons. Two pumping stations have been added and a new steel headframe has been erected at one of the shafts. The reorganization will not be finally completed for another two years. The cost of working has not yet been reduced and will not be until the reorganization is more nearly complete. In fact, the costs during the past half-year have necessarily been a trifle higher than when the mines were working individually, owing to the many temporary expenses. The benefit of this extra expenditure will be felt later. The life of the consolidated mines is estimated at 50 years. The market quotation of the shares, nominally 10s., is £8¼.

The Ferreira is one of the oldest mines on the Rand, having started operations in 1887. It is on the outcrop between Robinson and Village Main Reef. In the earlier days the content used to average 1¼ oz. or £5 per ton, and the cost of mining and milling varied from 35s. to 55s. per ton. Before the war the average profit per ton milled was over 50s. per ton. Since then the equipment has been increased; the yield per ton has gradually decreased from 13½ dwt. in 1902 to 9.6 dwt. in 1909. The cost per ton has decreased from 33s. in 1902 to 15s. 6d. in 1909. The life of the mine is drawing to a close and will probably come to an end at the beginning of 1913. The present equipment consists of 120 stamps and 3 tube-mills, of which latter one was put into commission during June of last year. The report for 1909 shows that during the year 339,150 tons of ore was treated in the mill, with an average content of 10 dwt. The yield by amalgamation was 113,740 oz., being an extraction of 6.7 dwt., leaving 3.3 dwt. on the tailing. This was subsequently treated in the cyanide plant and yielded 45,376 oz. In addition, accumulated sand and slime produced 3810 oz., and brought the total production to 162,926 oz., the value of which was £685,843 or 40s. 5d. per ton. The mining and development cost was £147,694 or 8s. 8d. per ton and the cost of metallurgical treatment was £88,449 or 5s. 3d. per ton. In addition, administration cost £26,493 or 1s. 7d. per ton, bringing the total cost to £262,636 or 15s. 7d. per ton. The profit was £423,207, and the balance brought forward from the previous year was £357,203. For the year 1909 a dividend of £570,000 has been declared, being at the rate of 600% on the nominal capital. As regards the future the ore reserve on December 31 last was 937,619 tons with an average assay-value of 8.65 pennyweights.

The Frontenac Consolidated company has been formed for the purpose of amalgamating the properties of the Frontenac Mining Co. and the Adduddel Mines Co. and extending operations. The properties consist of mines on the same vein three miles south of Central City, Gilpin county, Colorado. Henry P. Lowe is the manager. The ore consists of auriferous sulphides, some of the gold being caught by amalgamation in the battery and the remainder recovered by concentration. The vein has been intersected at a vertical depth of 1800 ft. by the Newhouse tunnel. The Frontenac company has been working since 1906 and has sunk a shaft 720 ft. and driven eight levels totaling 5500 ft. A stamp-mill and concentrating plant with a capacity of 60 tons per day has been erected, and the producing stage was reached in the middle of 1909. The Adduddel company is

not so far forward as regards production, but 6000 ft. of development has been done. The actual ore exposed amounts to 30,718 tons with an assay value of $9.73, and the profit is estimated at $100,939. It is estimated that the output above the level of the Newhouse tunnel will be 344,216 tons, giving a profit of $1,256,484. By means of the present flotation, additional capital will be obtained whereby the treatment plant will be extended to 300 tons per day.

Mining in the Newhouse Tunnel.

The capital of the company is £300,000, of which 70,000 shares of £1 each are now being issued for the purpose of raising the necessary funds. The properties have been examined by S. W. Tyler, Forbes Rickard, and by a representative of Alexander Hill & Stewart.

KALGOORLIE, WESTERN AUSTRALIA

Presidential Address at Chamber of Mines. — Water Pipe Troubles. — Patent Litigatioa.—Associated Head-Frame. — Institute Meeting.—Filter-Presses.—Monthly Output.

During the month of March there were good developments in the Hainault, Ivanhoe, and Perseverance mines, at depths ranging from 500 to 2100 ft., and mining generally on the belt is in a sound condition. The gold yield from the State was valued at $2,500,000. From the President's address at the annual meeting of the Chamber of Mines, the following may be of interest: "The results of the past year have not been altogether commensurate with our wishes, which are always in the direction of growth and improvement, but we have very fair reason to be satisfied with the work and the results obtained. The general rule of the past five years was maintained as to increased tonnage treated, shrinkage in the gold output, and dwindling profits. In 1909 the total quantity of ore treated was 3,105,094 tons, yielding gold to the value of $33,480,000. The tonnage shows an increase of 23,180 tons over that of 1908, while the value of the gold produced is $415,000 less. The ore grade is still declining; it dropped from $10.56 in 1908 to $10.32 in 1909. On the other hand the working costs increased from $4.62 in 1908 to $4.84 in 1909, and $640,000 less was paid in dividends by gold mining companies. I would again emphasize, as I did last year, the urgent need of keeping down working costs to the lowest possible level, otherwise the mining industry must suffer, since no high-grade mines have been lately discovered to compensate for the falling grade of the existing mines in the State. To do this will, I know, be exceedingly difficult. In the Kalgoorlie field, which is still the backbone of the industry, we have to face the problem of dearer water, dearer fuel, and the higher costs incidental to deep mining. Speaking generally of the mines in the back country, their special difficulty is the practice pursued by the Arbitration Court of granting what appear to me to be unwarranted increases in wages. I would direct your attention to that part of the council's report which deals with this matter, and especially to the following sentence: 'For the future it will be the duty of the mining employers to take advantage of every reasonable and legitimate means to endeavor to bring down the rates of wages, and the cost of commodities to a standard more commensurate with the existing state of the industry'." Many other points were dealt with, such as ventilating the mines better in view of deeper workings; decline of capital invested in new mines; the Government's work in connection with explosives used in the mines, and miner's phthisis; and the gold-stealing evil.

Mention has been made in these notes from time to time of the Water Scheme, and the corrosion that is taking place inside and outside of the main. Investigations have been carried out in England by Sir A. Bennie, Son & Deacon, Sir W. Ramsay, and Otto Hehner, who report that external corrosion of the water-pipes is due to (1) deterioration of the protective coating, (2) the pipe being buried in trenches when it should have been carried on trestles, so as not to be in contact with the surrounding soil, the soluble salts contained in which give rise to corrosion when moisture is present. For external corrosion, the best protection is held to be scraping the affected part, painting with bitumen and tar, and wrapping with tarred hessian. If laid in trenches, the pipe should be laid in a bed of lime concrete, a half-inch layer of CaO on top. The CaO would entirely prevent corrosion should the coating be damaged and moisture obtain access to the pipe. Internal corrosion is due to the failure of the coating. To scrape and re-coat is out of the question. Oxygen is the cause of the nodular incrustation. It is proposed (1) to prevent air entering the main at any point; and (2) that three grains of CaO per gallon be added to the water as it is pumped from the reservoir. The cost of the improvements suggested would be $935,000, and annual working cost $11,500. These experiments are of great value, as 443 miles of pipes are affected internally and externally. The water itself is very pure indeed; but the country the main passes through is very salty. We have had five hot and dry months, and the water consumption keeps high. In February, 102,347,000 gal. were used, returning $83,000; and for eight months of the financial year, 716,434,000 gal. for $755,000.

A big case of much interest in metallurgical circles is to be tried in Perth next month, as the London & Hamburg Gold Recovery Co., Ltd., which controls the patents out here for the use of bromo-cyanide, is sueing the Golden Horseshoe for some $300,000 for royalty not paid. The case is sure to be highly technical, and an abstract will be written for the readers of the Journal when the matter is decided. The Associated company has just erected a fine head-frame on the main shaft. This is made out of 18 by 20-in. Oregon timber, and is 102 ft. high. It was built over the old head-frame, which will be left in position, as a part will serve for the new 7½ Gates breaker and ore-bin to be erected in connection with self-dumping skips in the shaft. This work was carried out without delaying the usual hoisting. The Lake View Consols has started its No. 5 Krupp ball-mill wet crushing along with its 75 stamps. The screens used are about 28-mesh, against the 15-mesh on the battery. So far the mill is crushing 30 tons per day, but a thorough test will be made before long. Lack of tube-mill capacity prevents the coarser screen being used on the ball-mill.

During the month the local branch of the Australasian Institute of Mining Engineers met at the Chamber of Mines for the quarterly meeting. There was the usual representative gathering of mine managers, metallurgists, and

others. There was further discussion on roasting practice generally; the advantage or otherwise of cooling the roasted ore before mixing with the weak KCN solution; why the ore in the furnace tends to 'ball'; depth of ore in the furnace; and so on. It appears that this discussion will run on for several meetings yet. At the meeting written about, a paper on 'Filter-pressing' was read by M. W. von Bernewitz. The paper dealt with analyses of the ore before and after roasting, grading tests, details of agitation, filling, washing, and discharging presses, full details as to the cloths, plates, solution values, and soluble gold left in the cakes, costs, extraction, re-treatment of residue as against the vacuum process, and some experiments on sluicing-out presses. Discussion on this paper will take place in June. Every meeting seems to go off with greater swing, and much information will be forthcoming as discussion continues. The representative of the Butters Filter company is here investigating processes in use. The press still holds the lead here, but for how long is uncertain. The new hoist on the Kalgurli has been erected and is at work. It is a Corliss type engine built by Fraser & Chalmers, with cylinders 20 by 60 in., and will hoist nine tons from a depth of 4000 ft. It is fitted with special over-winding safety gear. All the clutches, reversing gear, and brakes are operated by steam. The returns from the principal mines were as follows:

Name.	Tonnage.	Value.	Profit.
Associated	11,108	$75,800	$2,300*
Associated Northern	3,137	21,000	3,000
Chaffers	4,038	31,500	2,500
Golden Ridge	2,479	31,000	14,000
Golden Horseshoe	25,739	210,000	40,000
Great Boulder	18,459	248,000	127,000
Great Fingall	10,784	87,500	10,200
Hainault	5,927	39,500	7,500
Ivanhoe	19,474	208,000	100,000
Kalgurli	10,940	140,000	75,000
Lake View Consols	11,362	77,000	12,000
North Boulder	1,200	34,000	.....
Oroya-Brownhill	21,596†	26,000	13,500

South Kalgurli	9,212	60,000	11,000

*Loss. †Old residue only.

TORONTO, CANADA

Cobalt Development.—Porcupine District.—Metagama Coal and Petroleum Deposits.—Explosives Regulation.

The general use of electric power is having its effect in gradually increasing shipments from Cobalt, and improving the physical condition and prospects of the camp. The most encouraging signs are the more favorable reports from the leading mines, the Nipissing and La Rose, the annual statement of the former being particularly satisfactory, showing an actual production during 1909 of 4,727,231 oz. silver, and a decrease in the cost of production from 20.7 to 16.39c. per ounce. The profit on operations amounted to 68.53% of the gross. The most hopeful feature is the marked increase in the ore reserves, estimated by Mr. Watson, the manager, at 6,539,200 oz. silver, as against 2,156,000 at the beginning of 1909. There are 132 known veins on the property. At the La Rose some rich orebodies have been opened on the Lawson property, both on the 48 and 88-ft. levels, the latter being regarded as a highly important development. In the main workings of La Rose proper, several veins have been proved at greater depths, and three veins of the Princess are yielding good ore. There has been a renewal of the rumors of a contemplated merger of the Nipissing and La Rose, and possibly other companies, but no definite steps to that end have so far been taken. The stock market is steadier and a feeling of greater confidence has arisen, but speculation in Cobalt stocks is practically dead. The Temiskaming directors have issued a report for the quarter ended April 30, showing cash liabilities of $190,820, and cash assets of $180,188, with profits amounting to $96,486. The veins are holding out well in depth, No. 2 at the 400-ft. level averaging 8 in. and assaying 4000 oz. silver per ton, while No. 1 is in good ore at 350 ft., and No. 3 carries 6 in. of high-grade at 390 ft. The new mill of the Nova Scotia is in operation, but only 10 stamps are being used at present. It will shortly be running to its full capacity of 100 tons per day. A new lead has been struck on the 100-ft. level from which rich ore is being taken. At the Trethewey a 6-in. vein assaying 4000 oz. silver per ton has been struck on the 150-ft. level. Development on the 280-ft. level of the Cobalt Lake near the McKinley-Darragh boundary has disclosed good ore. There are 13 stringers of ore in the face of the drift, two of them 3 in. wide, containing smaltite which assays between 2000 and 3000 oz. silver per ton. A vein discovered a short time ago on the Nipissing property has been traced to the Little Nipissing and appears to cross it. Assays from ore at the surface run as high as 2000 oz. The new vein struck by the Little Nipissing at the 210-ft. level has been opened by a drift for 100 ft.; over 300 tons of ore have been extracted from it. On May 18 the camp was visited by the members of the Canadian Press Association, 130 of whom are making a trip through the mining districts of northern Ontario. Sir Mackenzie Bowell and Senator Jaffray were with the party.

Many prospectors and mining men are going into the Porcupine gold district. W. E. H. Carter, a mining engineer, and H. E. T. Haultain, professor at the Toronto University School of Mining, have gone to make an inspection of the district. Important discoveries have been made on the North Vipond property owned by the Porcupine Gold Mines, Ltd., where a vein 5 ft. wide has a high-grade streak in the centre 2 ft. wide, showing native gold which will yield several hundred dollars per ton. A shaft is being sunk on the vein. Willet G. Miller has gone to investigate the reported discoveries of coal along the Metagama river. Numerous prospecting parties have lately been busy in that region, and it is claimed that a good quality of cannel coal has been found underlying the lignite. R. Horschitz, of Pittsburg, has staked four claims for an American syndicate. The United States Steel Corporation is also in the field, represented by R. J. Flaherty, who is said to have found large deposits of coal, iron, and salt. Strong indications of petroleum are reported throughout this region. Hon. W. Templeman, Canadian Minister of Mines, has in preparation a measure dealing with the use and storage of explosives, as a means of preventing accidents. It is proposed to create an Explosives Division of the Department of Mines, to which will be entrusted the testing and regulation of all explosives. A Government testing station will be established and drastic regulations passed against the use of unauthorized explosives.

WASHINGTON

Oil Land Legislation.—Agricultural Entries on Coal Lands.—Geological Survey Appropriations.—Land Examinations.

The enterprise displayed by the oil men of California in their campaign against the bill authorizing the President to withdraw the public lands from entry is exciting much comment in conservative Washington. It was not long after the bill passed the House that the Californians learned their interests were at stake. The bill as passed, if finally enacted into a law, would have withdrawn all oil lands from entry that were located subsequent to September 27, 1909. Congress heard from the oil men as fast as the words could come over the wire. Members of the Senate were asked to delay the passage of the bill until a delegation could arrive from California. They were told that the proposed law would be a coast-wide calamity; that the effect of any retroactive law would be immediately to stop the production of fuel oil to such an extent on lands on which a discovery of oil has been made since September 27, 1909, as at once to raise fuel oil to prohibitive prices and to allow large concerns owning patented lands to charge such price as the traffic would bear, thus creating such a monopoly of oil among the large interests such as has never existed in the United States. Another delegation telegraphed, "You can't conserve oil like coal and other minerals. It flows to nearest pumping well." Another wired, "Patented land

owners continue operations, thus depleting pools at small operators and Government expense." When the telegrams were read in the Senate, Reed Smoot, Senator from Utah, said that he thought the good people of California were under a mistaken apprehension as to the withdrawal bill. He explained that the bill known as the Pickett bill had already been acted upon by the Senate Committee on Public Lands, and that the enacting clause which permitted the withdrawal of the oil lands had been stricken from the measure. As the bill now stands, he said, there is no provision for the withdrawal of oil lands. Nevertheless this did not satisfy the Californians who have now reached Washington and are in the midst of a series of hearings before the House Committee on Public Lands, of which Frank Mondell, of Wyoming, is chairman. The bill will undoubtedly pass the Senate in its amended form and the amendments will be accepted by the House.

The Mondell bill, permitting agricultural entries on coal lands, has passed the House and is now before the Senate with a number of amendments. Joseph M. Dixon, Senator from Montana, will ask for a speedy hearing. In his report he says, "About 15,000,000 acres of lands have already been classified as coal lands, and about 45,000,000 acres are now withdrawn for classification, of which probably half will be eventually classified as coal lands. This represents an area of country about as large as the States of New York, Massachusetts, and Vermont. A great portion of this vast territory is suitable for agricultural entry, but under the homestead law cannot be entered as homesteads for the reason that the land contains coal. The situation is most urgent, as thousands of homestead entrymen are ready and anxious and willing to enter these surface lands as soon as remedial legislation can be had." The Sundry Civil bill, the last of the great appropriation measures, contains the following items: California Débris Commission, $15,000; public lands service, salaries, and commissions of registers and receivers, not to exceed $570,000; contingent expenses of land offices, $295,000; protecting public lands from fraud, $750,000; for surveys and re-surveys of public lands under the supervision of the Commissioner of the General Land Office, $450,000; toward surveying public lands in Valley, Dawson, Custer, and Fergus counties, Montana, $100,000; for United States Geological Survey, salaries, office of director, $34,860; scientific assistants, $29,900; for skilled laborers, $20,000; for topographic surveys, $350,000; for geologic surveys, $225,000; for chemical and physical research relating to the geology of the United States, $20,000; for preparation of report on mineral resources, $75,000; for gauging streams and determining the water supply of the United States, $100,000; for engraving and printing geologic maps, $100,000; for the investigation of fuels, $100,000; for the continuation of the topographic surveys of the public lands that have been or may hereafter be designated as national forests, $75,000; for subdivisional surveys of the public lands in Alaska and the preparation of the necessary maps and field notes, $40,000; for the investigation of mine explosions, $150,000; a total of $1,347,390 for the Geological Survey. An amendment is added to the bill authorizing the mine inspectors in the territories to inspect coal and other mines in the District of Alaska, to which district the provisions of this act are to be made applicable. The appropriation for testing structural materials has been cut from $100,000 to $50,000 and the work transferred from the Geological Survey to the Bureau of Standards in the Department of Commerce and Labor. It is thought that the passage of the Bureau of Mines bill nullifies this.

BUTTE, MONTANA

Parrot Opposition to Anaconda Consolidation. — Unwatering Ophir Mine.—North Butte.—Corbin and Radersburg Districts.

The dissenting stockholders of the Parrot Copper & Silver Mining Co. have instituted proceedings in the district court in Butte to have their stock appraised, as provided by the laws of Montana in cases where minority shareholders oppose the sale of property but can not prevent it. At the recent special meeting of the Parrot company, held in Butte, a small number of shareholders, represented by W. D. Kyle, as attorney, voted against the acceptance of the offer of the Anaconda Copper Mining Co. to purchase all of the Parrot assets for 90,000 shares of the new Anaconda stock. Under the State law action toward getting an independent appraisement of the value of their shares had to be taken within 20 days after the meeting. As no proceeding had been instituted in court within the 20 days it was generally assumed that the objectors had decided to make no further fight, but it appears from the pleadings filed in court that legal notice of a demand for an appraisment and payment under the award was served on both the Parrot and Anaconda companies by the protesting stockholders on May 18. The circular recently issued by the Western Development company through its vice-president, Calvin O. Geer, is attracting some attention, but among mining men there is a belief that the offer to exchange one share of United Copper company preferred for one of Anaconda, has been made solely in the interests of the United Copper company. The Anaconda company denies any connection with the deal and in order for the Western Development to carry out its part of the offer it must go into the open market and purchase Anaconda stock. The offer of the Western Development is not regarded seriously, but is considered an effort to boost the stock of the United Copper company which was organized to take over the assets of the bankrupt firm of Otto Heinze & Company.

Veiw of Part of Butte, Montana.

The work of unwatering the Ophir mine of the Butte Central Copper Co.'s property has been commenced with all the machinery in good working order. It is now estimated that it will take fully two months to get out all the water and this will mean that it will be about the first of August before the Ophir will be ready for active mining. Some good orebodies have been cut in the Raven mine and it is stated that it will not be long before regular shipments are commenced. Development is going along steadily and the company is reported strong financially. The energetic development which was promised at the annual meeting of the North Butte company is to be carried out. It is intended to sink the main shaft another 200 ft. and possibly 400, and cross-cut at these points as well as advance the development on the Croesus and adjoining veins. The work of constructing the new concentrator of the Butte & Superior mine is proceeding, and while there has been some

delay there is now a complete force of men at work, and unless some unforseen trouble arises the management expects to have the mill running in about three months.

The Corbin-Pennsylvania Mining Co. is the name of a company recently organized in the Corbin district with a capitalization of 500,000 shares of the par value of $1 each. The property acquired consists of six claims and is situated within half a mile of the Great Northern railway. On the east it adjoins the Boston & Alta property and on the northwest is the Boston & Alta and the Chicago & Alta extension, while on the south it is bounded by the Montana-Corbin. H. E. Emmerson, manager for the Boston & Corbin, is president of the new company, W. D. Gibson, superintendent of the Montana-Corbin, vice-president, and H. M. Brooks, secretary and treasurer. The Corbin Copper Co. will have its 200-ton concentrator in operation in about two weeks. When the mill is in working order the company will treat about 150 tons of ore per day which will come from the Dewey and Bonanza adits. The new electrical machinery for the Keating Gold mine, in the Radersburg district, will be in operation inside of two weeks and the company is expecting to increase its shipments of ore as soon as it is in working order.

BRITISH COLUMBIA

North Star Sold.—Rossland Shipments.—Slocan Star to Resume.—Greenwood Smelter to Blow in.— Fife Working. — Sheep Creek Items.

The North Star mine, at East Kootenay, is reported to have been sold to the Consolidated M. & S. Co., of Canada, Ltd. It is near Kimberley, Fort Steele mining division. Years ago this was the chief producing silver-lead mine in British Columbia. Its aggregate production to 1906, inclusive, was 69,500 tons of ore averaging, approximately, 30 oz. silver per ton and 40% lead. Production during recent years has been small; in 1909, it was only about 3000 tons of ore containing 39,000 oz. silver, and 711,000 lb. lead. The ore contains an excess of iron in oxidized form, and very little sulphur, consequently the smelting rate on it is low. Mining costs have been $2.33 per ton of ore. Tonnage of ore produced at Rossland during five expired months of current year aggregates 92,000, of which nearly 80,000 tons is from the Consolidated Co.'s Centre Star group. The Nickel Plate mine, long idle, is now leased and shipment of ore has been commenced. At Slocan, Byron N. White, of Spokane, president of the company owning the Slocan Star group, is arranging for mining and milling operations. The main workings of the Slocan Star mine have been closed for several years pending settlement of the lateral rights case of Star Mining & Milling Co. *v.* White, which was disposed of last fall. The company's concentrating mill, which makes both zinc and silver-lead products, will again be operated, after having been idle for years. The railway between Kaslo, on Kootenay lake, and Sandon, in the heart of Slocan district, is again being operated. Several years ago snowslides took out some big trestle bridges and these were not replaced. The road has lately been again placed in running order over the final eight miles which had been idle three or four years. An incline raise is being made from near the breast of the 2000-ft. adit driven last year by the Deep Mine, Ltd. The old workings of the Whitewater Deep mine are a total distance of 500 ft. up from the low-level adit, and connection is to be made with these. The present contract is for 150 ft. of raise and for exploratory drifts when that distance shall be reached.

The shipment of ore has not been resumed by the B. C. Copper Co. from its various mines to the Greenwood smelter, although all trouble between the company and its men has been settled. It is expected that work will be resumed with a good force of men in a few days, when the large furnace at the smelter will he blown in. The two other furnaces, which are being enlarged, will not be ready for work until about the first of June, when heavy shipments of ore will be made by the company to its smelter. Much new track is being laid and more electric motors added to the Mother Lode mine equipment. The company has only about half of its regular crew at work yet. There are about 40 men at work on the No. 7 property of the Consolidated company. Most of the work now being done is surface work. A deal is pending for the Highland Queen mine, near Greenwood.

The complete plant is now working well at the Fife mines, Rossland, and about 20 men are at work on development. It is not the intention to make steady shipments until considerable ore is blocked out, it is stated. A good strike of ore has been made in the main tunnel 500 ft. from the portal. The ore here carries over 5% copper and $4 to $6 in gold.

The Sheep Creek district seems to be the centre of attention hereabouts these days. The Queen is being examined by Richard A. Parker, of Denver, for Eastern capitalists. Mr. Erlund, of New York, is also at the property. Rumor has it that the Guggenheim interests have a bond on the Queen for $500,000. This property is now owned by Wisconsin people. It is equipped with air-compressing plant and 20-stamp mill, and has paid good dividends for several years past. There is considerable activity on Deer and Wolf creeks, and several of the properties have been examined by mining men in the last few days, including Haggen & Oliver, of Vancouver, and Shallenberger, Seelye & Mayer, of Spokane. The mill-run (of 568 hours) for the month of April at the Van-Roi mine, is summed up in the following figures: ore crushed, 4269 tons, yielding 140 tons lead concentrate, assaying 210.7 oz. silver, 62.6% lead, 10.8% zinc, and 100 tons zinc concentrate assaying 74.2 oz. silver, 3.4% lead, and 43.9% zinc; approximate value, $19,834. The shipment of ore from the Society Girl mine, Moyie, will soon be made possible by the new wagon-road being built to the property. An electrical lead-zinc experimental plant has been erected at Cranbrook and some tests on local ore will be made.

NEW YORK

Market Conditions.—J. Parke Channing on Porphyry Coppers.—Ray Con.—Utah Copper and Nevada Con. Listed.— Guggenheim in Alaska.—Cobalt.—British Columbia.

Wall Street has become a Sargasso sea. An unbroken calm broods over the market. Interest in mining matters is at its lowest ebb. The copper situation is much confused. About the only figures, apparently, upon which reliance can be placed, are those of the producers. The statisticians are evidently uneasy over the possibility of hidden supplies which might suddenly be added to the 'visible', while on the other hand it is admitted that all of the existing accumulation could be immediately absorbed if buyers would carry the usual stock. It is generally understood that there is to be something of a war between the smelter crowds, and that in this the copper mines will figure as important factors. In some quarters there is talk of a combination, or, at least, of an understanding which will save open warfare, but nothing definite has yet appeared. Copper authorities are pointing to the fact that known consumption, that is, deliveries known to be going to genuine users of the metal, is breaking all records and that the present surplus is not proportionately larger than at many times past. It is true that production is running about 10% ahead of consumption and that some of the low-cost producers, whose only possible profit lies in an enormous output, are now on a basis where curtailment is impossible. There is also the further fact that some of the low-cost coppers now in the making have already cost so much that developments cannot be sidetracked and their production must be thrown on a glutted market. It is this state of affairs that causes buyers to stay out of the market. The law of inertia holds good in regard to the steam-shovel coppers. It takes a mint of money, years of time and labor to get one of these properties started, but when started, it cannot be stopped but must be kept going. Recent discussion of the possibilities of the porphyries has called from J. Parke Channing a very pertinent interview, in which he says: "It is ridiculous to put down the costs of most of the new copper properties, which have never yet turned a wheel, to 7½c. per pound. Yet this very thing

is being done on all sides, and it looks to me as if the indiscriminate use of such low cost figures is mostly responsible for the present lack of buying in our copper market. Large consumers take the view that if so many properties are going to produce copper for 7½c. a pound, they might just as well hold themselves aloof from the market until such a time as the metal sells lower. I have never claimed better than costs of 9c. per pound for ores of the Miami Copper Co., yet in a number of tables that I have seen, in which the figure of cost was given, I have invariably found the latter placed below 8c. In addition, operators who are taking every step they know of to show what a tremendous amount of copper their properties will be able to produce within 12 or 18 months' time are not helping the copper situation in any light, whatsoever. These statements of tremendous output which are made also have an influence tending to keep buyers out of the markets. The worst of it is, that, when these predictions are sifted to rock bottom, one finds that they are usually 50% greater than the most flourishing of possibilities. It is a form of exaggeration which in my opinion is largely responsible for the present low price of the copper metal."

While the predominance of the porphyries may for the moment aggravate the untoward conditions of the copper metal market, they have exerted a widespread influence upon the mining share market which has been wholly beneficial and which is extending, and has already extended far beyond the limits of copper mining shares. This is the lesson taught, largely through these issues, of regarding and studying mining from an investment point of view. It is true that the public, carried away by the realization that this type of mine eliminated the element of uncertainty, became over-enthusiastic and forced these issues to higher

Red Rock Shaft, and Experimental Mill at the Miami.

levels than can be justified. Perhaps nothing demonstrates more fully this temporary reversal of sentiment toward the copper list than the complete lack of interest in the preliminary merger of the developing properties in the Utah Copper group. The recent announcement of the consolidation of Ray Consolidated and Gila was received without comment, and while the combined property is claimed to be potentially equal to Utah Copper, there has been no market response. In fact, both issues have sagged materially. The stockholders' meeting called for the ratification of the proposed consolidation was held this week and the necessary increase in the capital stock of the Ray Consolidated from $10,000,000 to $12,000,000 was authorized by unanimous vote. Notwithstanding the inevitable reaction and the present decline in enthusiasm and some drastic shrinkage and heavy losses incurred, the lesson will remain and mining investors will not forget what they have learned in regard to ore reserves, average values, extraction costs, depreciation charges, and many other vital features, which hitherto were never considered by the general public in mining matters. The more the general public becomes educated in regard to mining, the better for the industry, as well as the public. The progress made along this line is illustrated by the admission of Utah Copper, and Nevada Con. to trading privileges on the New York Stock Exchange. Goldfield Con. is preparing to ask for trading privileges and it may be expected that others will strive to follow their example. In fact, it is the step in market progress that is one of the underlying causes of the present stagnation in mining issues. Some of the larger California oil companies as well as some of the industrial 'trust' shares are being removed from the speculative field and placed in the investment class, that there should be a momentary halt and a re-adjustment as this step is made is to be expected. The Guggenheims, who seem to have been the disturbing factor in the projected merger last winter, are in the spot light again owing to a bitter attack upon their actions in Alaska in connection with the J. P. Morgan interests. The Senate Judiciary Committee at Washington is holding meetings behind closed doors. James Wickersham, delegate from Alaska, is known, however, to have made startling charges, in connection with the accusation that the Morgan-Guggenheim syndicate tried by fair means and foul to completely dominate Alaska and secure control of all of its natural resources. Members of the committee are moving to force public hearings, and sensations are expected.

The long lethargy of the Cobalts has been broken. Nipissing and La Rose moved up sharply on the rumor of an interim distribution of 5% by the former and a re-establishment of the latter on its old dividend basis of 16% as against its present rate of 8%. The talk of merger was immediately revived upon the show of some activity in the stocks; both companies concede the desirability of consolidation but evidently think the time is not yet arrived to make the move. The smelter of the British Columbia Copper Co. is to be blown in after a shut-down of more than six weeks. The labor difficulties have been adjusted and there are enough men now on the payroll to operate mine and mill and everything is expected to be in full blast by the middle of June. Shipments from the claims recently acquired in the Wellington district are to be received immediately, as the Canadian Pacific railway is just completing its spur track connecting Wellington with the smelter, so that the furnaces will have the benefit of this additional tonnage.

SALT LAKE, UTAH

Bingham District Active.—Utah Con. Tramway Tested. — Ohio Copper Preparing for Extensions.— Changes at Silver King. —Tintic News.

The annual report of the United States S. R. & M. Co. in referring to the company's property at Bingham states that the tonnage of ore already developed is sufficient to keep the plant running at present capacity for some years. The profits for the year were materially increased by the installation of a Huff electrostatic mill by means of which the zinc in the ore is made a source of revenue. The baghouse has been in successful operation during the past year or more and the capacity of the concentrating plant has been increased. The International smelter at Tooele will be ready for operation some time in August, probably near the first of the month. The plant will commence to receive ore some time in July as a reserve of 40,000 to 50,000 tons is desired, once the plant is started. The tramway of the Utah Consolidated from the mine at Bingham has been completed and is being tried out, but the company is not yet at liberty to ship to the Tooele plant as it is held by a tonnage contract with the Garfield smelter which it will not complete until about the time that the International plant is ready to receive ore. The new contract should work well for the Utah Con. Not only will it be relieved of the toll that it is now obliged to pay the Garfield plant, but it will be enabled to ship a larger tonnage than at any time since its own plant was closed and the transportation by aerial tram will be a decided advantage over the present method of shipment which is by tram to the lower part of town and thence by rail to the smelter. During the last year a new orebody has been opened up below and north of the fault that two years ago was said to have cut off the vein entirely. This orebody is somewhat better in grade, in fact it is estimated that it is sufficiently better to more than offset the added expense of mining at the lower level. The Utah Metals Co. is pushing work on the tunnel which is to connect Bingham with the International smelter. That portion which has already been driven has been straightened out and enlarged so as to be uniform

with the rest of the work, namely, 8 by 10 ft. in size with accommodations for two 24-in. tracks which will be laid with 35-lb. rails. A new pipe-line has been built to the source of supply up Middle canyon that gives ample electric power for the work, and a new generator unit has been installed. Each generator has individual connection to a Pelton wheel. W. J. Allison, a prominent banker from the East, has been going over the Ohio Copper Co. with Colin MacIntosh, the manager. No definite announcement has been made at this time, but the supposition is that now that Heinze's troubles are over the completion of the mill will be undertaken. The mill was designed for 3000 tons and a corresponding building erected, but only one-half the machinery has been installed. The North Utah has bought into the Bingham Copper Co., presumably to a considerable extent as W. D. Bohm, manager of the North Utah, has assumed the management of the Bingham. Clearing out the old workings has been commenced. It is expected that after the stockholders' meeting which is to be held at Cheyenne, Wyoming, on June 20, operation will commence.

In the Park City district the operating staff of the Silver King Coalition is to undergo a pretty general shaking up. George D. Blood, consulting engineer for the company, will become assistant general manager in active charge of all mining operations in place of M. J. Daly. M. F. Sammon, formerly mine superintendent for the Bingham Mines Co., will become mine foreman, in place of Frank Daly. The reason given for the change is ill health on the part of the Daly brothers, but it is generally believed that the company desires a higher standard of efficiency than in the past. Whether the embarrassing disclosures made in the suit of the Silver King Consolidated against the Coalition had anything to do with the change can not be learned. The annual meeting of the company was held recently and the old officers and directors re-elected. The Daly-Judge has also re-elected its old board and officers. Work on the Snake Creek tunnel in which the Daly-Judge is largely interested is progressing at the rate of 15 ft. per day. The tunnel is now about 200 ft. under cover. It is the largest undertaking of the kind in Utah. It will be 14,000 ft. long and 6½ by 9 ft. above the tracks, with a concave drain 3½ by 4 ft. below. Power is furnished by the company's own electric plant on Snake creek. A lateral may be driven through the divide into Alta. The Little Bell is making plans for a concentrating mill to treat a large tonnage of low-grade ore. The company has a considerable amount of high-grade ore and has been paying dividends since last December, but desires to increase its earnings.

In the Tintic district the work of sinking the McChrystal shaft of the Eagle and Blue Bell is progressing, although the new equipment is not expected until July. The McChrystal is to be carried to the 1000-ft. level, and made the main working entry of the mine. This level is being extended under the shaft and as soon as the point is reached work will be carried on by raising and sinking at the same time. The present hoist is good for only 800 ft., but as the shaft is only down 200, will be made to do until the new hoist, which has a capacity of 2000 ft., is installed. The activity here is another indication of the intentions of the Bingham Mines Co. At a recent meeting of the directors of the Lower Mammoth the levying of another assessment was voted down by a large majority. The mine probably can now take out sufficient ore to at least pay expenses. A winze from the 1800-ft. level is in good shipping sulphide ore. The Mammoth shipped seven carloads of ore running $60 to $80 per ton last week, and the lower levels look so well that there is some talk of increasing the output. A few months ago this mine shipped one carload of ore that netted the company $100,000. Those interested in the geology of the Tintic district have a new cause for speculation in the strike in the Carisa of ore identical with that in Colorado, Sioux Con., and other mines on the Colorado fissure. The strike was made on the 500-ft. level and developed into a 3-ft. vein of characteristic Colorado ore. Several theories have been advanced as to the Colorado vein, one being that it bends out of Iron Blossom into the Carisa and another that it has a feeder running in that direction.

FAIRBANKS, ALASKA

Silver-Bearing Galena on Cleary Summit. — Test Runs on Gold Quartz.—Talk of a Dredge. — Redwing Leases Jupiter Mars.

Although the high-grade ores in this district so far have been those containing a large percentage of free gold, late discoveries show that other classes exist. Near the Cleary Summit, and in the same mineral belt with the free-gold ores, a deposit of silver-bearing galena has been lately uncovered. This assays 115 oz. silver and $2 gold per ton. Not enough work has been done to show the extent of the find. Masses of galena weighing several hundred pounds were found on the outcrop. Another base ore recently assayed for the first time, although discovered by a woodchopper a year ago, proves to be antimony, assaying 51 oz. silver and $18.75 gold. Although the exact location of this find is as yet pledged to secrecy, the district is one not far from Fairbanks and on the Chatanika river. The recent mill-run on 10 tons of ore from the Crawford lease on the Rhodes-Hall property yielded a 95-oz. retort. This shows the ore to run between $175 and $200 per ton in free gold. It is probable that at least $50 per ton was lost in the tailing, as there is no provision in the test-mill for saving concentrate. Mr. Crawford is now building an arrastre on Bedrock creek to run by water-power. In this he intends to grind his richest rock. Preparations are being made to timber the 60-ft. shaft in the Spaulding-Clough property before the thaw causes the shaft to slough. In this shaft the vein shows at least 3 ft. at the bottom and free gold can be seen in the rock. By lining up the strike of the vein with a small transit, Mr. Spaulding was able to find the vein 700 ft. farther down the creek and again at 1500 ft. from the Discovery shaft. The remarkably straight walls of the lode, together with the fact that after lining up the vein was found in the first hole sunk 1500 ft. distant, speaks well for the permanence of the orebody. The extension of the Spaulding vein has been staked by Mrs. W. L. Spaulding, Mrs. R. R. Meyers, Mrs. D. J. Fairburn, and Mrs. Raymond Brumbaugh. They have a valuable claim and have named it the 'Wild Rose'. Herschberger, Bueli & Phipps are still sinking on their lode on the saddle between Eldorado and Cleary creeks. The shaft is down over 40 ft. and shows high values in free gold. The gold is fine and can be seen with difficulty except with a glass. Under a glass it appears in clusters of bright colors. The main adit of the Rhodes-Hall claim has now been driven in 500 ft. The ore is still good, the vein varying greatly in width, but showing a flattering average in width and value. Mr. Rhodes will soon send in a shipment of ore. On Chatham cheek, the Pioneer Quartz Mining Co. has run into rich stringers while cross-cutting for the main vein. The rock is being sacked for future treatment. The partners, Ringseth, Giske, and Larson, are thinking of building an arrastre to handle the richest of the rock. Lawson, Sommersett & McCarty have struck the vein in their cross-cut farther down the hill. The opening between the walls averages about 30 inches, with 20 of quartz that is worth $100 per ton. There is talk of installing a dredge on a group of claims owned by the Blaker Bros. on Goldstream. The ground is 35 to 50 ft. deep and averages $1 per square foot of bedrock. As most of the overburden is muck with a large percentage of water, no trouble is anticipated in working the ground, once the pit is started and a face exposed.

The Tolovana Mining Co. has just shipped in 9 tons of rich quartz to be put through the Fairbanks test-mill. Returns should show at least $150 per ton in free gold, as hand specimens show a plentiful supply of coarse gold. The Redwing Mining & Leasing Co., Inc., of Nevada, has taken a two years' lease on 400 ft. of the Jupiter-Mars Con. Mining Co.'s ground on Chatham creek. The lease was taken after a thorough sampling by S. R. Calvin. The Redwing company is a close corporation controlled by Emil Furstenau and S. R. Calvin. The terms of the lease call for an immediate commencement of work, the development to be carried on continuously. A working shaft that will open up two levels at 100 and 200 ft. is called for, with a certain amount of driving on each level.

General Mining News

ALASKA

(Special Correspondence).—The Mount Andrew mine shipped 400 tons of ore during May on the *Jennie*, and will have 1200 tons ready to forward the early part of June. The development is being carried ahead rapidly and a large amount of ore is blocked out in the mine.——The Chicago Exploration Co. has taken a lease on the Unuk river placers, which contain 6000 acres of gold-bearing gravel, and will start work at once.——R. G. Mellen, representing the Tyee Copper Co., is examining properties in this district and recently completed the examination of the Poor Man mine on Kasaan bay.——Development at the It mine is proceeding favorably, the gold content in the ore showing a fair increase as depth is attained.——On the Veta, near McLean's arm, Ickis & Polson have intersected the vein in a crosscut run from the shaft at a depth of 30 feet.

Ketchikan, May 18.

The report of the Alaska Mexican Mining Co. for the month ended April 15 states that the 120-stamp mill ran 30 days 14 hours during the month, crushing 19,315 tons of ore. The estimated value of the free-milling gold amounted to $30,938, and of the concentrate $27,244, the realizable

Alaska.

total value being $55,713. The operating expenses amounted to $19,818. The report of the Alaska United Gold Mining Co. for the same period gave the running time of the Ready Bullion mill as 28 days 14 hours. It crushed 18,820 tons of ore, producing 405 tons of concentrate which, with the bullion, was worth $42,582. The 700-Ft. Claim mill ran 30 days 15 hours, crushing 16,616 tons. The operating expenses amounted to $24,495, and the total value realizable from the ore was $31,362.

ARIZONA

COCHISE COUNTY

The ore-pocket at the 1600-ft. station of the Sacramento shaft of the Copper Queen mine at Bisbee, has been completed after considerable trouble with loose ground. The drifts on the 200 and 300-ft. levels between the Czar and Holbrook shafts are being put in working order and supplies will be handled through these while the Holbrook is being retimbered.——Drift No. 15, at Denn-Arizona, opened a body of oxide ore. There are about 40 tons of ore on the dump that will average between 8 and 9% copper.——Regular shipments of wolframite ore are being made from the claims of P. Climmons at Dragoon. Some vanadium ore has also been opened on one of the claims of this group.——The Arizona Mining & Milling Co., operating at Patagonia, has ordered 10 additional stamps for the mill which will double the capacity of the plant.——The shaft at the Scott & Crawford, at Paradise, is now down 45 ft., and a small amount of copper ore has been taken out.

GILA COUNTY

(Special Correspondence).—A third shift of 10 men has just been added to the working force at the Old Dominion concentrator.——The Williams shaft, on the National Mining Exploration property, has been sunk to a depth of 708 ft. A new level will be established 778 ft. from the surface.——Churn-drill hole No. 3 at the Live Oak mine cut chalcocite at a depth of 300 ft. a few days ago and has since passed through 55 ft. of ore averaging 2.5% copper. This hole is 700 ft. west of the vertical shaft, and shows the Live Oak orebody to have an east and west extent of fully 861 ft.——On the property of the Kasser Gold Mining Co., in the Lost Gulch region nine miles from Globe, a combination churn and core-drill is being set up preparatory to prospecting the property. The Kasser holdings embrace 27 claims. Ballard Day is in charge of operations.——The Pinal Mountain Mining Co. has recently found ore containing copper and gold in the adit by means of which the property is being developed. The ore runs from 3 to 14% in copper and assays from $5 to $12 gold per ton. H. H. Harvey is in charge of the work.

Globe, May 27.

PIMA COUNTY

The new 25-hp. engine has been installed at the Chesterfield Copper Co.'s property and hoisting started from the 400-ft. level. In the south drift from the west cross-cut a shoot of silver-bearing galena has been opened that will assay 20 oz. silver per ton, and the ore is being hauled to the railroad at Twin Buttes and shipped from there to the El Paso smelter.——A contract has been let to sink the shaft of the Gold Bullion in the Baboquivari mountains 100 ft. which will take it to the 275-ft. level where cross-cuts will be run to the vein.

YAVAPAI COUNTY

Grading for a new hoist at the Tomboy mine in the Castle Rock district has been started and a road to haul the machinery over is under construction. As soon as the hoist is in position a two-compartment shaft will be sunk from which the company plans extensive development work.——The Alvarado company has completed the connection between its two deep shafts on the 1000-ft. level a distance of over 1000 ft. The work has been entirely on the vein and has opened a body of commerical ore.——The adit at the Gold Ridge is in 725 ft.——At the Yarnell a large body of ore assaying from $7 to $10 per ton has been opened and a winze has been started in the ore from the main adit-level.——The Mountainside Mining Co., organized to operate the Stanton-Rich Hill mine, has commenced work on the property and is overhauling the mill to test the value of the ore.——A 10-stamp mill is being erected at the Mildred.——Davis & Hurley, who are operating the Octave mine under lease, started the mill a few weeks ago and are reported to have made a fair clean-up.——The United Mines Co., of Congress, is operating the 30-ton plant and shipping a good grade of concentrate.

YUMA COUNTY

The New La Paz Gold Dredging Co. is preparing to commence work on its placer ground on the Colorado river near La Paz where a number of rich placer properties were worked in the early days of the State.

CALIFORNIA

EL DORADO COUNTY

A 7-ft. vein of free-milling ore was opened recently by the drift on the 500-ft. level of the old Pacific mine which is within the city limits of Placerville. The mine is being re-opened after an idleness of twenty years, and while the extent of the shoot has not been determined the ore is well sprinkled with gold and has the appearance of permanance.

NEVADA COUNTY

The new shaft at the Cassidy property opened a shoot of $39 ore when down 20 ft. C. M. Wilson is in charge of the work.——The Ethel mine has been unwatered below the main level and the mill overhauled. The force has been increased and development work will be started at once.——The lower drift at the Republic mine, operated by William McLean & Co., at Graniteville, opened a shoot of free-milling ore. The mine was under bond to an Eastern company some time ago, but as no amount of ore was found the bond was relinquished and the McLean interests again took up the work.

PLACER COUNTY

An examination of the Imperial gravel mine at Michigan Bluff is being made by H. S. Detwiler and George Denny, and if found satisfactory the outstanding stock will be purchased by Eastern stockholders and the mine re-opened.

SIERRA COUNTY

(Special Correspondence).—Fifteen men are sinking the winze at the Sixteen-to-One. Until this has been completed production will be suspended.——The Croesus Mining Co., operating the Plumbago mine, has its mill in steady operation and is treating the usual grade of ore.——The owners of the Federal claim have been enjoined from driving their tunnel into ground claimed by the South Fork Mining Co. ——The first payment on the Ramshorn group has been made by S. Arnold and associates of Goldfield.——Plumas county capitalists are examining the Young America quartz mine near Sierra City and are planning to resume operations if examinations prove satisfactory.

Alleghany, May 28.

An adit has been started on the serpentine contact on the Higbee claim near Alleghany that is claimed by its owners to be the extension of the Tightner.——A contract has been let to drive the adit at the Monte Cristo property 400 ft.—— The drift from the Mott shaft on Rock creek is being extended to the west, and it is thought by the owners that they will have to sink deeper to open the channel.——W. W. Old has secured a bond on the American Flag group of claims in the western part of the county and work will probably be started in a short time. The Gibraltar gravel mine is to be started some time this month. Last fall the hoist broke just as the ground was being well opened, and operations were suspended for the season.——The upper adit at the Sargent claims in Slate Castle ravine has opened the shoot a distance of 60 ft., showing the vein to be 5 ft. wide and to average $30 per ton.

SISKIYOU COUNTY

The clean-up for the first month's run of the mill on the Oom Paul mine near Greenville amounted to $2400, which is considered satisfactory by Pickard & Nagle, who are operating the property. A lower adit has been started that will tap the vein 75 ft. lower than the present workings and a drift is being run that will open another shoot 400 ft. distant.

TUOLUMNE COUNTY

(Special Correspondence).—The Wickham mine, situated near Jeffersonville, has been bonded to Carlow & Hensley, of Sacramento, who will at once commence the further development of the property and install a 5-stamp mill.——At the Ida Klein mine, near Stent, work is confined to driving on the vein and stoping. The 3-stamp mill is in steady operation on high-grade ore from the north drift, where a shoot estimated to be 300 ft. long has been opened.——Sinking is progressing satisfactorily at the Mariana copper claim, situated near Chinese Camp, with indications steadily growing more favorable.——The Gold Crater Mining Co. is erecting a 10-stamp mill at its property on Knight's creek.

Tuolumne, May 28.

COLORADO

GUNNISON COUNTY

The melting of the snow in the Dorchester district the past month has made the roads almost impassable and greatly retarded mining operations in this vicinity. The water-power plant at the Enterprise mine has been completed and is now driving the compressor that furnishes the air for drilling, dynamos, and mill.——Work is to be resumed early this month in the North Star and Extension groups of Charles Hubbard.——A force of men has been started on the Mahlgren group and the high-grade lead ore will be shipped this summer.——The contract in the Pie Plant adit has been completed and a new one let that is thought will complete the work.——The Bonanza lead mine that was opened last season at the foot of Italian mountain has found a good grade of ore and will soon commence shipping.

LAKE COUNTY

The northern extension of the Cleveland fissure at Leadville has been opened in the Valley property and a 30-ft.

Davis Hydraulic Mine, Siskiyou County.

shoot of gold ore found.——The Ibex mine is shipping about 7500 tons of ore per month which is being drawn from the four shafts on Breece hill.——The shoot has been opened on the third level of the St. Louis, showing the vein to be 5 ft. wide and to assay 1 oz. gold, 18 oz. silver, 24% zinc, and 16% lead.——Since starting operations on the Silver property last fall the lessees have taken out over $35,000 worth of ore and have now opened a large body which will be worked through the Little Emma shaft as soon as connections can be made.——Work has been started on the Kennebec property and about 15 tons of ore per day is being hoisted.—— The new electric hoist at the Silent Friend is in good working order and active mining will be started on the lower levels as soon as they are drained by the bore-hole from the Yak tunnel.——Work has been started replacing the plant at the A. Y. and Minnie mine which was destroyed by fire a short time ago. For the present operations will be conducted through the pump-shaft at the foot of Iron hill in California gulch.——Frank Zaitz and associates have commenced work on the New Emmet property and are shipping about 25 tons of lead ore per day.——The Birdelia adit which the Gleason Gulch Mining Co. is driving is now in over 700 ft., and is expected to open the President and Amity veins within the next 100 ft.——The Yankee Doodle mine on Carbonate hill is shipping from 25 to 30 tons of ore per day.

OURAY COUNTY

A long drill-hole has been run from the face of the deep adit that has been driven to tap the lower levels of the

Caliope mine near Ouray, and the old workings are being unwatered. Considerable ore has been taken from the mine and it is expected again to become a regular producer. ——Fred Herzinger, who is operating the Black Girl mine, has blocked out a large amount of stoping ground and is shipping regularly.——Two cars of ore were shipped recently from the Wedge mine, which is under lease to F. M. Jackson.——A contract has been let to sink the shaft at the Brazilian-Monitor 125 ft. and work resumed at that property.

SAN JUAN COUNTY

John Paul and John Rohave secured a lease on the tailing from the Gold King mill at Silverton and are erecting a small plant to treat the material, which assays from $6 to $8 per ton.——There is a large amount of ore in the bins at the Vermillion mine near Animas Forks and the mill that was erected last year will soon be started.

SUMMIT COUNTY

The St. Johns Mining Co. is re-grading the road from the mine to Montezuma and will soon commence shipping ore. The old property is developed by several miles of workings and it is taking considerable labor to get the mine in good condition.——The Moctezuma Mines Development Co. has started the mill and is hauling the ore from the mine to the plant.——F. and J. W. Burke are working in the adit on the Deer creek side of Glacier mountain that will open their property 1000 ft. below the present workings of the mine.——The owners of the Ohio-Toledo have completed the mill building and are installing the new machinery. The main adit is being driven ahead and development carried forward on the veins already opened.

TELLER COUNTY

Stoping by the lessees of the Jennie Sample mine in the Cripple Creek district has been stopped temporarily to allow the company to re-timber the shaft which has been declared unsafe by the mine inspector of the district.—— Schaeffer & Co., operating a lease on the second level of the Anchoria-Leland, have opened a shoot that assays between $25 and $30 per ton and are preparing to make a 35-ton shipment.——The lessees of the Eclipse group of Battle mountain have installed an electric hoist at the main shaft of the property and are unwatering the lower workings which have been filed to the 200-ft. station.——The Success Leasing Co. has purchased the sub-lease of the Union Leasing Co. on the Beacon claim for $500, and will install a hoist and compressor.——Buckmaster, Price & McIntyre, leasing the Home and J. J. L. claims of the Commonwealth Mining & Milling Co., opened a shoot of high-grade ore on the 300-ft. level and have commenced shipping.——The Blue Bird Mining Co. has resumed operations and will further develop the lower levels, opening them for lessees.——The Copper Mountain mill is reported running steadily and saving a higher percentage than has previously obtained. At present about 25 tons per day is treated, but this will shortly be increased to the full capacity of the plant. The ore treated is mined from both the surface deposit and the adit workings on the Fluorine mine and is estimated at about $4 per ton.

IDAHO

IDAHO COUNTY

Washington B. Van Delip, of New York, has secured a bond on the Mammonite group of W. F. Newton, and the Illinois of Smith Brothers in the Ten-Mile district. The claims are among those staked this spring between Big Leggett and Little Leggett creeks. The whole district is active and a train of 60 mules is kept busy packing in supplies from Grangeville.——The repairs to the dredge on Little Elk creek in the Elk City district have been completed and the machinery is running again.——New machinery has been ordered for the Crackerjack mine in the Hump district operated by the Mines Co., Ltd., and will be hauled to Stites as soon as the roads will permit of lower freight rates.

SHOSHONE COUNTY

The Caledonia Mining Co., operating in the Coeur d'Alene district, which paid its second monthly dividend, disbursing $13,000 at the rate of 1c. per share, on May 25, announces that 40 tons per day of crude ore is being sent to the smelters. The company paid a dividend of 2c. per share in April. ——The Monarch mine has just shipped its first car of concentrate to the smelter at Bingham. The renovation of the mill on the property was completed a short time ago, and the machinery is running smoothly. The mill is to be enlarged, but for the present 10 cars of ore per month will be shipped. The mill's capacity is from 75 to 100 tons per day and this will be increased to 250 tons.——Stringers of rich galena have been cut in the lower adit of the Interstate mine, adjoining the Rex and Callahan properties in the Nine-Mile canyon, six miles from Wallace.——Operations at the Paragon property in the Murray district will soon be resumed and the plant restored. The shaft-house was demolished and its equipment scattered by a snowslide last winter. The house will be re-built and the machinery reinstalled. When the work is completed the property will be prospected with a diamond-drill from a point near the bottom of the shaft.

MONTANA

LINCOLN COUNTY

The Comet Placer Mining Co. has a force of men at work on the property on Cherry creek south of Libby preparing the mine for the season's run and sluicing will be started in a few days.——The board of directors of the Lincoln Gold Mining Co. at a recent meeting held in Spokane voted to add 15 stamps to the mill, making a total of 45 in the plant.

SILVERBOW COUNTY

From the statements for the year ended December 31, 1909, of the companies which will be included in the merger in the Butte camp under the ownership of the Anaconda Copper Mining Co., submitted in an application for the listing of the increased stock at New York, an approximate idea of the earning power of the stock may be gained. The following table shows the net profits and copper produced:

	Net profits.	Pounds copper produced.
Boston & Montana	$3,029,120	101,951,530
Anaconda	2,134,773	75,860,194
Washoe	1,732,673	80,559,625
Butte & Boston	751,712	20,955,910
Red Metal	566,988	34,654,971
Trenton Mining & Development	165,112	7,168,318
Big Blackfoot Milling Co	191,724	.....
Diamond Coal & Coke	86,421	.....
Total	$8,658,523	301,150,368
Parrot Silver & Copper (loss)	132,965	5,407,255
Alice Gold & Silver (loss)	6,411	.....
Total loss	139,376	5,407,255
Net results	$8,519,147	306,557,623

The outstanding capital stock of the Anaconda Copper Mining Co., after all the merger exchanges shall have been made, will amount to 4,220,000 shares, of a par value of $25 per share, making a total par value of $105,500,000.

NEVADA

CLARK COUNTY

The orebody on the 400-ft. level of the Nevada Eagle mine in the Eldorado district has been cut for 22 ft., showing it to have an average value of $12 per ton. Arrangements have been completed for the installation of a mill, and the plant will probably be in full operation this fall.——At the Rich Hill property the company has started grading for a 10-stamp mill and concentrating plant. This will be operated in connection with the Nelson smelter, which is owned by this company and will treat custom ore.——The Capital Mines Co. has cross-cut to the vein on the 200-ft. level and opened a large body of sulphide ore. A 50-hp. hoist is to be installed at once and plans drawn for a 10-stamp mill. The company is now shipping ore in 10-ton lots to the Needle smelter.——The Success Mining Co. has purchased the Doly mill, installed in the Eldorado camp

near the Colorado river 25 years ago, and will place it on the June Bug claim.——On the Truax & Martin both shafts are in ore, samples from which assay from $30 to $70 per ton.——It is reported that the Occidental mine, which is equipped with a 35-ton Bryan mill, is to be worked in the near future.——The Sphinx, which has been idle for the past two months, has again resumed operations and the shaft will be sunk from the 200 to the 500-ft. level.——Work has been resumed on the Little Black Hawk property, which has been idle for over two years.

ELKO COUNTY

The adit of the Jarbidge-Pavlak company, operating at Jarbidge, cut the Taft vein at a depth of 150 ft., opening stringers of high-grade ore. The adit will be driven 400 ft. additional to tap the Pavlak vein.——The shaft of the Pick & Shovel is now 50 ft. on the hanging wall of the vein. W. W. Scott is superintendent.——Frank C. Williams, manager for the St. Lawrence Mining Co. at Shoshone, and J. B. Simpson, of Ely, have secured a five-year lease and bond on the claims of Mrs. D. A. Algens in the Lucin district. The mine has a production record of over $500,000, though it has been idle for the past 25 years. The old workings are being cleaned out and new machinery will be installed, when shipments will be started to the smelters.

ESMERALDA COUNTY

There is considerable work going on in the Cuprite district 14 miles south of Goldfield after an idle period of about two years. The owners of the Kerigan-Smith-Evans property have purchased an 18-hp. hoist and will sink the shaft from the 110-ft. point to the 400. W. S. Evans is manager. The sulphur deposits at Cuprite will soon be extensively developed. Ellsworth Oldt and associates, who have large holdings in the sulphur belt, are now completing negotiations for the erection of a refinery, and it is likely that within a few weeks work of construction of the first unit of the refinery will be started.——The directors of the Goldfield Consolidated Mines Co. held their regular quarterly meeting at Goldfield May 26 and declared the regular quarterly dividend of 30c. per share with an extra dividend of 20c. per share payable July 31 to stockholders of record June 30. The total disbursement of 50c. per share will amount to $1,779,549 and is the third consecutive dividend that has been declared in like amount. The underground work of the company is in excellent shape and the entire mill is expected to be in operation early this month.——The old Victor shaft on the C. O. D. Consolidated property is being put in shape for active work, and operations will soon be started under the direction of L. D. Koontz. Steady development is in progress on the Gray lease on the Gold Bar claim of the C. O. D., and although no shipments are being made at present it is expected that the increased work will open some good shipping ore.——The west drift on the 700-ft. level of the Yellow Tiger is now out 300 ft., the face being in a hard silicified dacite. It is expected to open the shoot on which a winze was sunk from the 600-ft. level in a short distance.

LYON COUNTY

Extensive changes are planned for the Nevada-Douglas by the officials of that company. A new compressor plant will be installed, a new transformer house built, and an electric-power line run to the Ludwig mine. A new ore-bin will be added to the one now in use, doubling the present capacity. The two bins will hold 700 tons of ore. A tramway 1600 ft. in length will be put in, running from the top of Douglas Hill to the railroad, the difference in elevation between the top of the hill and the end of the tramway at the railroad being 600 ft. In addition to the surface improvements the company contemplates extensive changes underground, and before fall at least 40 men will be put on development work. At the present time the company has 625,000 tons of ore, which will average 5½% copper, blocked out ready for extraction, and it is expected that this tonnage will be doubled before the smelter is blown in. The company also will begin at once the development of its gypsum beds, so as to start shipments as soon as the railroad reaches the mine.——A hoist is to be installed on the Bluestone Extension and active work resumed on the claims.

NYE COUNTY

(Special Correspondence).—The new vein in the Belmont is 12 ft. wide and has been followed about 16 ft. by the shaft, showing the ore to be of good milling grade. The Belmont 60-stamp mill at Millers has been started and 220 tons per day will be milled, while small shipments of high-grade quartz will be made to the smelters.——Herman Zadig and associates of San Francisco have re-incorporated the Tonopah Rescue Co. and are arranging to resume work.——The long delayed machinery for the 100-ton mill of the Bonnie Clare Mining Co. has arrived and will be installed immediately.——The Bullfrog-Mohawk is installing a plunger pump with a capacity of 2500 gal. per hour and will sink the shaft to the 500-ft. level. The pump will be operated by a 20-hp. gasoline engine.——The management of the Johnnie Consolidated reports a profit of $7340 for the three months of February, March, and April. During this time 6114 tons of ore were treated. Total costs of mining and milling are from $3.85 to $4.35 per ton, while the average recovery from ore milled is $6.09. The output for May has been slightly increased, while the installation of the new Lane mill will result in a further gain in June. The shaft is being sunk to the 800-ft. level.

Tonopah, May 28.

The Round Mountain Mining Co., at its office in Goldfield, declared its ninth consecutive dividend of 4c. per share, amounting to $34,650, on May 25, making the total dividends $293,733. This is payable on June 25 to stockholders of record on the books of the corporation June 20. The new vertical shaft going down 900 ft. east of the main works is said to be in pay-ore to its present depth of 130 ft., and it is expected that this condition will continue to at least 200 ft. This new work will open up an entirely new country, and will furnish a large tonnage to the mill. The present capacity is steadily maintained at about 130 tons per day, but this is to be increased to 150, which will for the immediate present be the limit.——There are 1000 tons of ore on the dump of the Swanson-Ross-Lyon lease on the Earl mine at Manhattan which will be treated in one of the local mills at an early date. The shaft is now down 200 ft. on the vein and it is the intention of the lessees to continue sinking several hundred feet farther.

STOREY COUNTY

The lowering of the water at the C. & C. shaft is the chief point of interest in the work on the Comstock Lode, and excellent progress is being made, several sections of the column and rods of the old Cornish pumping system having been taken out. The shaft has now been practically cleaned out to the present water-level, which is approximately 175 ft. below the 2350-ft. station. The timbers in the shaft below the 2450 to this point are in a fine state of preservation.——In the Ophir and Consolidated Virginia mines there are no important new developments this week. In Consolidated Virginia the taking up of the water will allow prospecting work in the deep levels, but no new work has yet been started. Stoping of ore from the 1750 and 1800-ft. levels continues, and Ophir is shipping ore to Kinkead's mill. In the latter mine no changes are reported from the 2300 or 2400-ft. levels.——At the Mexican mine the operations for the past few weeks have been dead work, it being necessary to do considerable timbering in the workings on the west vein on the 2300-ft. level. On the 2400-ft. level the west cross-cut from the winze-station is being continued and is in vein material. In the winze the additional pump has been installed on the 2200-ft. level, which is easily taking care of the small flow of water above this.——At the Ward shaft work has been started setting up one of the three new pumps to be installed on the 2100-ft. pump-station, the first one being placed at the west end of the station.——The pumping plant at the Monte Cristo is doing excellent work and has lowered the water in the shaft from 15 to 20 ft. There is a big territory to drain and progress is slow.

WHITE PINE COUNTY

The work of grading for the new 10-stamp mill which will be erected at the Willow Patch near Osceola for the Amalgamated Nevada Mines & Power Co., has been started

by the Traylor Engineering Co., which has a contract for the work. Most of the machinery has been delivered at the mine and the rest is at the East Ely depot and will be hauled to the property at once. A small force of men has been started in the San Pedro mine, and if the supply from this property is not found sufficient to keep the mill busy, operations will be started at the Mable and other holdings of the company.——A cross-cut from the main adit at the old Cornell mine near Hamilton, operated by A. B. Witcher and Charles Minnoletti, of Ely, opened a body of lead-silver ore that assayed over 25 oz. silver per ton. A drift has been started along the orebody and shipments will be started as soon as a stope can be opened.——O. E. Turner, president of the Ely Central Copper Co., is the moving spirit in the organization of the Huebnerite Tungsten Co., which was recently incorporated. The new corporation, which will develop a group of tungsten properties about 12 miles south of Osceola, is capitalized for $100,000, divided in shares at the par value of $1 each.

UTAH

BEAVER COUNTY

After several weeks of preparatory work two diamond-drills have been installed in the Black Bird mine and the ground will be thoroughly prospected.——Two cars of silver-lead ore were shipped a few days ago from the Cedar-Talisman and a shipment of zinc is soon to be forwarded. The new orebody has been proved from the 125 to the 500-ft. level, and on the 500 the drift has been driven 500 ft. showing the vein to contain five feet of shipping ore and two of milling.——The drifts on the 300-ft. level of the Rob Roy are opening a 30-ft. vein in which some excellent ore has been found. There is a mill on the property but no ore has been treated recently as the company has not been able to develop a shoot of any length, the ore being rich but patchy.

Map of Utah.

IRON COUNTY

At Gold Springs the differences between the Western Electric Co. and the Gold Springs M. & P. Co., which resulted in the application for a receiver for the latter, have been adjusted out of court, and the power-plant of the Gold Springs company will be ready to go into commission before long. The motors and compressor at the mine are being installed.

WASHINGTON

FERRY COUNTY

The Pacific Ore Reduction Co., of which E. R. Davidson is president and general manager, has broken ground for a 100-ton cyanide mill at Republic, where custom ore from the district will be treated. The schedule of charges ranges from $3 to $4.50 per ton, according to the grade of ore, and settlements will be made on delivery, on the assay value of each lot. Contracts for tonnage already have been signed by a dozen producers. The equipment will consist of rock crushers, Chilean mills, four 25-ton cyanide tanks, and an air-compressor. Tests show that the best extraction is obtained by crushing to a fineness of 80 mesh and subjecting the pulp to treatment by a mild solution of cyanide from 8 to 24 hours.

MEXICO

OAXACA

(Special Correspondence).—The passenger and freight trains are now running regularly in the Taviche camp. With the advent of the train, and the re-opening of the San Juan mine under American management, there is a general improvement with various other properties in this district. Some properties which have been closed down for two years are now getting ready to resume development work.——Malcolm McLeish, of Denver, has during the past week, made a contract to treat the tailing of the Los Reyes mill, by cyanide process. J. G. Gray, receiver of the Los Reyes properties, has been making an examination of the company's interests, with a view to resuming work.——Frank W. Leonard has sold a one-fifth interest in the San Martin mine for $100,000. The purchasers are Canadian capitalists, and in connection with Mr. Leonard expect to operate the property along modern lines.——A railroad concession has been granted by the Government to the Oaxaca Coal & Iron Co., for a road from Puebla, through the Oaxaca coalfields in the Tlaxiaco district, to the west coast near Salina Cruz. The road will open territory, both mineral and agricultural, heretofore practically unexplored.

Within the past month there has been organized in Wichita Falls, Texas, the Wichita Falls Mexico Mining Co., with a capital of $750,000 United States currency. The company is composed of leading business men of Wichita Falls, who have already bought the Santa Rosa and Nevada claims in the Nochistlan district. J. A. Morris, who is also manager for the Georgia Mexico Mining Co., operating a mill in the same district, will have charge of the initial work.——N. O. S. Ford is making an examination of the Taviche camp, for a proposed custom mill to be installed at Santa Inez.——The first payment has been made on the proposed hydro-electric plant, which will utilize the waters of the Tomellin canyon, for supplying Oaxaca and neighboring camps with electric power. The plan includes the acquiring of the local lighting and power-plant and the electrification of the local street car lines.

Oaxaca, May 25.

SONORA

(Special Correspondence).—Frank J. Nichols, of Douglas and Clifford Robertson, of El Paso, who have an option on the Agua Buena mine, are dewatering it preparatory to examination by Kansas City and Chicago capitalists. The mine is situated 18 miles south of Nacozari.——Two hundred sacks of ore have been shipped this week from the gold property of Herbert Walters in the Barigon goldfield near Nacozari. This is a new district where rich gold quartz was discovered only three months ago. Another mine in this district is that owned by the Montenegro Mining Co., the Mexican holding company of the Barigon Mining Co. This property is about five and a half miles northwest of Nacozari, and has been opened by 4000 ft. of development work.——The Transvaal Mining Co., operating west of Cumpas, will not smelt any ore at its little smelter till the Southern Pacific railroad is extended from Nacozari to Cumpas. Most of the grading and cut work is now completed on this extension.——A. J. King and associates have now completed repairing the wagon-road from the El Tigre road to the Cinco de Mayo and Roy mines in the El Tigre district. The old mill at the Roy mine has been repaired and put into operation, and about 1400 oz. of silver concentrate is now ready for shipment to El Paso.

Nacozari, May 28.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

GAS AND OIL LEASE—CONSTRUCTION

A lease granted to the lessee the right to produce oil and gas from certain lands for ten years with the exclusive right to drill and operate oil and gas wells, to lay and operate pipe-lines, with the necessary right of way over the premises, and a sufficient quantity of lands to preserve the products, and that when oil or gas should be found in paying products the lessor would extend the lease from year to year so long as such production continued and limited the lessee's use to so much of the land as might be necessary for the purposes named. In a controversy over the lease as to the exclusive use of the land, the lease was construed to give no general or exclusive right to lay and operate pipe-lines, but only sufficient rights in that respect to enable the lessee to carry out the main object of producing and removing oil and gas, and that a subsequent permission by the lessor to a third person to construct a pipe-line across such leased land to conduct oil from other lands to market was not adverse to the rights of the lessee in the land, until the lessee began to use the part of the land through which the leased pipe-line ran and until his use of that part of the land became incompatible with the maintenance of the other pipeline.

Brookshire Oil Co. *v.* Casmalia Ranch Oil & Dev. Co., (Cal.) 103 Pac. 927, Aug. '09.

LOCATION OF PLACER MINING CLAIM

Mining claims are not opened to re-location until the rights of a former locator have come to an end, and two locations cannot legally occupy the same space at the same time. In the location of placer mines, the surface is the thing located, and the position of the surface is absolutely essential to the mining operation. A valid mining location although unpatented is a grant and the estate enjoyed is in the nature of an estate in fee, and it is an appropriation of land by the locator to the exclusion of all others. There is no reason why a junior locator of a placer claim cannot lay his lines across a claim already located. But the rule is that an association placer mining claim cannot be located over other prior claims so as to include within its boundaries and to appropriate a number of unlocated and noncontiguous fractions lying between such prior claim.

Stengfeld *v.* Espe, 171 Fed. 825, May '09.

INJUNCTION TO PREVENT REMOVAL OF MINERALS

A court of equity enjoined the removal of iron ore by a person who had no right thereto, in order to prevent irreparable injury, though the owner himself was not in actual possession of the ore when the suit was commenced. And in such an action where the court had jurisdiction, and in order to do complete justice and prevent irreparable injury, it could settle the title to the ore.

Morrison *v.* American Assn. (Va.) 65 S. E. 469 Sept. '09.

CONVEYANCE OF MINERALS

A deed conveying without reserve all the iron ore under the land described to the grantee and his heirs and assigns forever, without any suggestion that the title should in any event revert to the grantor, was sufficient to pass a fee simple to the ore and not merely a license to operate the mine.

Morrison *v.* American Assn. (Va.) 65 S. E. 469, Sept. '09.

RE-LOCATION OF MINING CLAIM—EFFECT

Persons who asserted rights to a mining claim as re-locators on the theory that the claim had been forfeited for failure to perform the required assessment work, were held to have recognized as re-locators the prior location, which became forfeited by the re-location.

Golden *v.* Murphy (Nev.) 103 Pac. 394, July '09.

Company Reports

UNITED STATES SMELTING, REFINING & MINING

The fourth annual report of the United States, Smelting, Refining & Mining Co. shows a profit for 1909 of $3,136,360, compared with $3,017,947 in the previous year. Out of the earnings has been paid a U. S. Smelting preferred dividend of $1,700,693 and a dividend on common stock of $701,961. The output of metals was as follows:

	1909.	1908.	1907.
Copper, lb.	36,672,606	32,803,603	38,518,378
Lead, lb.	41,627,995	27,304,347	53,617,324
Silver, oz.	9,637,119	8,340,566	6,739,269
Gold, oz.	128,393	128,208	235,822

The percentage of value of each metal and the average price received in 1909 and 1908 were:

	1909		1908	
	Per cent value.	Price received.	Per cent value.	Price received.
Copper	33.81	13.006c. lb.	34.5	13.27c. lb.
Lead	12.58	4.297c. lb.	10.0	4.23c. lb.
Silver	35.06	51.969c. oz.	34.5	52.97c. oz.
Gold	18.55	.....	21.0	....

The total ore product from the Centennial-Eureka, Mammoth, and the United States mines at Bingham, and the Mexican mines, was 69,771 tons, yielding money values in the proportion of 42% copper, 5 lead, 35 silver, and 18 gold. The financial position of the company is shown in the appended balance sheet struck on December 31, 1909:

ASSETS

	1909.	1908.
Cost of properties	$40,518,486	$39,879,357
Deferred charges and operation	139,106	50,546
Ores and matte	781,863	666,321
Supplies, fuel, and timber	981,510	981,329
Metals in process and in transit	6,279,822	5,315,433
Notes receivable	865,360	628,489
Accounts receivable	703,418	970,795
Cash	1,807,238	1,329,724
Total	$52,076,807	$49,821,997

LIABILITIES

Common stock	$17,549,350	$17,549,125
Preferred stock	24,300,012	24,299,175
Capital of subsidiary companies not held by company	1,055,574	1,056,228
Debentures of sub-companies	.....	500,000
Bills payable	3,428,781	2,267,175
Current accounts payable	1,160,202	1,092,801
Drafts in transit	127,805	80,000
Reserves for freight, ref'g, etc.	463,608	371,697
Dividends declared not yet paid	600,793	600,717
Depreciation funds	1,599,389	973,450
Undivided surplus for stock sub-companies not owned	76,058	43,925
Profit and loss surplus	1,715,230	987,704
Total	$52,076,807	$49,821,997

The $500,000 6% debentures of the United States Mining Co. which matured May 1909 were paid at maturity. At the Midvale smelter in Utah the construction of the bag-house for filtering the smelter fume was completed during the year and the cost charged to capital account. At the Chrome refinery, New Jersey, a valuable tract of real estate adjoining the refinery lands was purchased. An adequate provision has been made out of earnings for the examination and exploration of new property. During the past year a smelter at Needles, California, and some promising mining territory near Kingman, Arizona, tributary to this plant, were purchased, as well as some other properties at present of minor importance. On December 1, 1909, Sidney J. Jennings was elected vice-president in charge of exploration and mining investment, and he is now actively in charge of this department.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

LEWIS HIND has gone to Sonora.

E. A. SPERRY was in San Francisco.

A. D. GEIGER has returned to Boston.

COURTENAY DE KALB is at Grass Valley.

H. D. MCCASKEY is expected at San Francisco.

W. M. KNOX has gone to Minas Geraes, Brazil.

C. H. MUNRO has gone to Nome for the season.

C. W. PURINGTON sailed for Yokahama on the *Tenyo Maru* May 31.

A. H. ELFTMAN was in San Francisco but left for Chicago and the East.

CLARENCE C. SEMPLE has returned from Nicaragua, and is in San Francisco.

S. F. EMMONS has gone to Dinard, France. He will remain abroad until October.

H. G. HANN, recently with the Camp Bird, Ltd., has gone to Siberia with C. W. Purington.

C. T. LAW, of LAW & WICHMAN, Salt Lake, is on his way to Alaska on professional business.

W. J. RICKELL has removed from Mina, Nevada, to Los Angeles, where he will open an assay office.

C. H. CLAPP is making geological surveys on Vancouver Island for the Canadian Geological Survey.

THEODORE GROSS, resident manager for the Hirsch Syndicate, Ltd., has returned to New York from London.

EARL R. PEMBROKE, of Salt Lake, is superintendent of the Mt. Gaines mine at Hornitos, Mariposa county, California.

F. M. WIEHMAN has been appointed general superintendent for the Bingham-New Haven mine at Bingham, Utah.

JACOB HASSLACHER, president of the ROESSLER & HASSLACHER CHEMICAL CO., of New York, is in San Francisco.

JAMES W. NEILL was in San Francisco. He has become managing director of the Mt. Gaines mine, Hornitos, California.

R. H. CHAPMAN is in charge of topographic surveys in British Columbia this season. His address is Vancouver, British Columbia.

WILLIAM R. JEWELL has become consulting geologist to the Globe Exploration Co., operating in the Sunset, Midway, and Coalinga oilfields.

R. A. F. PENROSE, JR., has been appointed as delegate from the Philadelphia Academy of Natural Science to the International Geological Congress at Stockholm.

GEORGE F. POWELL, manager for the El Tajo Mining Co., of Poza, Sonora, Mexico, has been in San Francisco and Denver inveatigating machinery for a new mill to be built at its mines.

COMMENCEMENT at the School of Mines and Metallurgy of the University of Missouri, was held at Rolla, June 1.

OBITUARY

JAMES ARTHUR DIGGLES, who died recently in New South Wales, was a graduate of Stanford University in 1895. After considerable experience in California he joined the staff of Bewick, Moreing & Co., and has for some years, been managing silver mines at Broken Hill. His death was due to heart failure following typhoid from which he had seemed to be recovering.

S. PEARSON & SON, LTD., the firm which has been in a bitter warfare in Mexico with the WATERS-PIERCE OIL CO., which is stated to have cost the Pearson interests $10,000,000, is soliciting subscriptions in London to the MEXICAN EAGLE OIL CO., capitalized for £30,000,000. This company, although only two years old, has established over 150 distributing depots and agencies throughout Mexico, and at present is constructing a pipe-line 60 miles long to connect its oilfields with shipping points.

Joplin Lead and Zinc Prices

The *News-Herald* figures for the week ending May 28, 1910, are as follows:

Zinc blende sold for as high as $43.50, basis of 60%, but the prevailing sales were made on prices ranging from $40 to $43. The top price for choice lots was $46 a ton, while the average price was $40.95, compared to $41.39 of the previous week.

Spelter was weaker than for the previous week, the close being quoted Saturday at $5.17½, compared to $5.20 of the previous week.

Calamine was unchanged at $20 to $24 basis of 40% grades, with a top price of $26, and an average price of $25.51, compared to $22.52 of the previous week.

Lead prices, both for ore and metal, were little changed. The prevailing offerings for ore were $48 a ton, the average paid being $47.82, compared to $48.68 of the previous week. Pig lead was stronger at $4.25, compared to $4.20 of the previous week.

Below are given the value of shipments from each district with a summary for the district, in pounds and total values:

Joplin: Blende, $32,760; calamine, $195; lead, $2600. Total, $36,555.

Webb City-Cartersville: Blende, $58,548; lead, $16,224. Total, $74,772.

Galena: Blende, $24,805; lead, $1488. Total, $26,293.

Granby: Blende, $5645; calamine, $4675; lead, $325. Total, $10,645.

Duenweg: Blende, $23,856; calamine, $806; lead, $528. Total, $25,190.

Miami: Blende, $20,615; lead, $3120. Total, $23,735.

Aurora: Blende, $832; calamine, $819; lead, $96. Total, $1747.

Alba-Neck City: Blende, $17,114.

Zincite: Blende, $1302.

Badger-Peacock: Blende, $10,619; lead, $47. Total, $10,666.

Oronogo: Blende, $23,555; lead, $58. Total, $23,613.

Carthage: Blende, $3990; calamine, $585. Total, $4575.

Stotts City: Blende, $2400.

Carl Junction: Blende, $4171.

Quapaw: Blende, $1680.

Sarcoxie: Blende, $4480.

Spring City: Blende, $1453; calamine, $598; lead, $240. Total, $2291.

Cave Springs: Blende, $288.

Summary for the district: Blende, 11,614,845 lb.; calamine, 594,970 lb.; lead, 1,087,790 lb. Values: Blende, $237,825; calamine, $7678; lead, $26,014. Total, $271,517.

Total for 22 weeks: Blende, 224,242,200 lb.; calamine, 18,361,230 lb.; lead, 35,869,445 lb. Values: Blende, $4,739,825; calamine, $231,203; lead, $944,849. Total, $5,915,877.

The ASSOCIATED OIL CO. last year produced 7,114,796 bbl. a portion of which it consumed for its own use. Its gross income for the year, both from sales of oil and its interest in transportation, pipe-lines, and other companies was $15,000,000.

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

Publications Received

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

PRODUCER GAS FIRED FURNACES. By Oskar Nagel. Pp. 192, ill., 237, index. Published by the author, New York, 1910. Price $2.

A good popular exposition of the principles and practice of producer-gas manufacture, and its applications, has been needed. Mr. Nagel has supplied the want. He has written a quite elaborate treatise, and his presentation of the subject is sound. All the leading producers, American and foreign, are illustrated and described. The details of construction of gas mains and accessory operations are given, after which comes an excellent chapter on conditions for the economic combustion of producer gas. The application in specific cases is taken up with thoroughness, accompanied by useful illustration. The list covers the chemical industries, metal industries, including the many applications to iron and steel manufacture; also lime and cement, glass, brick, and pottery. The present methods of purification of gas are described, but not as fully as might be desired. The chapter on refractory materials is also deficient in this regard, though containing much practical and suggestive comment. The book is one well worth careful perusal by anyone having to use producer gas.

THE MEXICAN POCKET LAWYER. Compiled by A. E. Ulloa. Pp. 209, index. A. Stein, Mexico, 1910. Price $1.25.

This little volume, small enough to be carried in the coat pocket, contains, in English, the recent fundamental laws of Mexico on patents, corporations, trade-marks, the new stamp law, mining law and regulations, and forms of documents, in Spanish, covering the following cases: applications for patent, registration of trade-mark, and for mining claims, power of attorney to obtain a patent, and the same for trade-mark. There are included the tariff of fees of mining agents, for collection of assay and melting dues, and conversion tables for weights and measures. It is an extremely convenient compendium, and should prove useful to all who require such information in English.

COPPER. By L. C. Graton, H. S. Gale, and G. W. Stose, U. S. Geol. Surv., Bull. 430-B. Pp. 65. Washington, 1910.

Advance pages from 'Contributions to Economic Geology', 1909, and including 'The Occurrence of Copper in Shasta County, California', by L. C. Graton; 'Geology of the Copper Deposits near Montpelier, Bear Lake county, Idaho', by H. S. Gale; 'The Copper Deposits of South Mountain in southern Pennsylvania', by G. W. Stose.

MINERAL PRODUCTION OF CANADA, 1907 and 1908. By John McLeish. Am. Rept. Div. Min. Res. & Statistics. Pp. 286. Dept. Mines, Mines Branch. Ottawa, 1910. Price 15 cents.

The usual review of mineral production with notes on production and consumption. An indispensable handbook for those interested in the Canadian mineral industry.

SURFACE WATER SUPPLY OF THE UNITED STATES. Part I. North Atlantic Coast. By H. K. Barrows and R. H. Boister. U. S. Geol. Surv. Water Supply Paper, 241. Pp. 346, ill., index. Washington, 1910.

Methods and results of stream gauging.

REPORT OF THE BUREAU OF LABOR STATISTICS, ILLINOIS, 1908. By David Ross. Pp. 592. Springfield, 1910.

Containing full statistics regarding production of coal in the State.

DEPARTMENT OF GEOLOGY, PRINCETON UNIVERSITY. Announcement of Courses for 1910-1911. Pp. 25. Princeton, New Jersey.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

J. H. J., Alberquerque, New Mexico: Rhyolite altering to chert.

S. E. M., Quartzsite, Arizona: Altered diabase containing veinlets of oxidized pyrite and gold.

G. R. D., Washoe, Nevada: No. 1, diorite; No. 2, fine-grained altered silicious rock with chalcopyrite.

C. M. C., Paradise, Arizona: No. 1, rhyolite breccia with small amount of limonite; No. 2, rhyolite; No. 3, rhyolite tuff; No. 4, quartzite; No. 5, rhyolite.

J. C. S., Danville, Washington: No. 9, rhyolite; No. 10, diorite; No. 11, diorite schist containing pyrite and pyrrhotite; No. 12, actinolite schist; No. 13, talc schist; No. 14, diorite; No. 15, diorite; No. 16, granodiorite.

J. M. L., Independence, California: No. 1, granodiorite altering to sericite; No. 2a, pegmatite; No. 2b, rhyolite; No. 2c, chert; No. 3, altered rhyolite; No. 4, altered gabbro; No. 5, altered igneous rock containing chalcopyrite.

The Rush to Iditarod, Alaska

Fear is expressed that the rush to the Iditarod will almost depopulate Fairbanks. Labor may be scarce, which will inconvenience operators who have large amounts of good ground blocked for summer work, although it is anticipated that many men will be back from the new diggings by August, as the unprecedented rush from all quarters will greatly over-populate the whole district. While this will encourage further prospecting, the small number of creeks showing pay, and the almost impossibility of getting heavy machinery into place before the next freeze-up, will mean an enormous overplus of labor all over the Iditarod. Numberless boats of all sizes, from 75-ft. steamers to power canoes, are at present building on the banks of the river, and, in fact, all over town, to join the rush down on the first water. All boats are designed to meet shallow water conditions, as hopes are entertained of making the mouth of Otter creek without transfer. Mining plants aggregating fully 1500 hp. will be shipped from Fairbanks and Chena, many of the boilers being used as motive power for steam barges. In fact, if the inspectors of hulls and machinery were to arrive here before the break-up, only a small fraction of the fleet would be able to sail. Only a portion of them are needed, according to the most reliable reports. There is no doubt but good ground has been found, but not enough to justify such a stampede.

Alaska Mexican Gold Mining Company

The Alaska Mexican milled 226,651 tons of ore during the year 1909, with an average assay value of $4.04 per ton. The ore reserves at the end of the year were 596,404 tons, including 201,350 tons broken and remaining in the stopes. The mill contains 120 stamps,, and the cost of milling during the period covered by the report was 24.31c. per ton. The ore yielded in free gold, including base bullion, $470,852 or $2.0774 per ton, and in concentrate $376,854, or $1.6627 per ton. The actual recovery was therefore $3.74 per ton, or 92.57%. The quicksilver lost was 28.44% of that used. Effective time for the mill during the year was 315 days, 17 hours. The stamp-duty was 5.37 tons. Renewals involved 482 shoes, 275 dies, 2 cams, 2 cam-shafts, 372 stems broken and replaced, 10 new stems, 37 tappets, 21 hoss-heads, 1 mortar, and 9 vanner belts. The operating profit was $468,424, and total profit $499,488. Four dividends, representing 40% on the par value of the issued stock, were declared, the sum disbursed being $360,000.

Work of the Bear Creek Dredge

The following account of the work of the Bear Creek dredge is condensed from the Dawson *Daily News* of November 26 last, and has been furnished by the courtesy of the Marion Steam Shovel Co., builders of the dredge in question. It is based on a statement given for publication by Joseph W. Boyle, manager of the Canadian-Klondyke M. Co., Ltd.

Three points are made by Mr. Boyle in his statement. One is that the actual operation of the dredge and power-plant, including maintenance and repairs, and all items of labor, fuel, and everything of the kind, was less than 15c. per cu. yd. Another is that the percentage of time lost by the dredge was less than that of a number of similar boats operated in California. The third is that the length of season is far greater than ever supposed to be possible here. Mr. Boyle expects to be able to run the dredge 224 days in 1910. In his comparisons of operation made by dredges in California, he quotes of D'Arcy Weatherbe, writing in the Mining and Scientific Press.

In California it is customary, explains Mr. Boyle, for the mining companies to furnish such data to the scientific press, and it is said it is due largely to such data being given to the public that the dredge industry has reached its extensive proportions and efficiency. "The operation of the Bear Creek dredge," he continues, "this year compares most favorably with those of the best boats in California, both as to the yardage handled and the lost time during the operating season. The dredge started digging at 11 p. m. on May 9, and stopped at 7 a. m., November 20, a total of 194 days

Marion Steam Shovel.

and 8 hours elapsed time. During that period the boat dredged 681,616 cu. yd. of material, or on an average of 3558 cu. yd. per day throughout the season. The total lost time for the season was 368 hours, 43 minutes, or 7.9% of the total running time. The published statement available showing yardage and lost time on dredges in Oroville, California, are as follows: A dredge using 5 cu. ft. buckets dredged in 1905 a total of 589,082 cu. yd., and in 1906 a total of 557,084 cu. yd., digging the whole 12 months in the year. The published statements showing lost time on some of the well known dredges in California are as follows: The Butte, 18.5% for 32 months; the Eltoro, 33.41% for 20 months; the Yuba No. 1, 32.8 for 12 months; the Yuba No. 2, 30.4 for 12 months. The latter two boats are the property of the Yuba Consolidated Gold Fields, and the 12 months included in the statement ended January 1, 1906. The Canadian-Klondyke Mining Company's dredge is of the 7½-cu. ft. bucket capacity electrically driven."

The Bear Creek dredge has several appliances not installed on any of the other dredges operating at Dawson which assist materially in lengthening the period of yearly operations. The principle appliance is a heating plant, with steam pipes extending the entire length of the enclosed stacker-ladder. These are placed either side of the stacker-belt in such a manner as to entirely prevent any freezing. There are also steam coils under the lower belt rollers, under the sluicing tables, in the enclosed house constructed over the main drive, and at all other points necessary to be kept free from frost. On different occasions during November, 1909, the dredge was operating in a temperature of more than 20° below zero, without the slightest difficulty and with all the efficiency which it would have had in the warmest weather. A system of applying hot water to the sheaves through which the various shore lines operate, prevent any difficulty from this quarter. Mr. Boyle states that the difficulties through which the dredge has successfully worked this season has been greatly exaggerated and that in his opinion the miners of this country overcame in the simplest manner much greater difficulties in the placer mining carried on in winter in the early days. The dredge was expected to start digging on or about April 1, 1910, and to continue at least to November 20. This will give a season of at least 224 days. The only difficulty experienced here in operating in the fall of 1909, according to Mr. Boyle, was from the surface frost. This was so thin that it was impossible to thaw with existing methods, but successful means have been devised and spring operations will be started as planned.

CATALOGUES RECEIVED

The Lane Slow Speed Chilian Mill Co., Los Angeles. 1910 Catalogue. 'Lane Mills'. Illustrated. 64 pages. 6 by 9 inches.

Denver Fire Clay Co., Denver. 1910 Catalogue. 'Assayers' and Chemists' Supplies'. Illustrated. 424 pages, 6¾ by 9½ inches.

American Gröndal Kjellin Co., New York. Bulletin. 'Concentration and Briquetting of Iron Ores'. Illustrated. 22 pages. 11 by 9 inches.

The Dorr Cyanide Machinery Co., Denver. Catalogue No. 3. 'The Dorr Classifier and the Dorr Continuous Thickener'. Illustrated. 32 pages. 9 by 6 inches.

Word Bros. San Francisco. 'The Drill Sharpener Book'. Showing the 1910 model Word Drill Maker and Sharpener for steel up to 50 ft. long. Illustrated. 20 pages. 7 by 5 inches.

Sprague Electric Co., New York. Pamphlet 233. 'Electric Hoists'. Illustrated. 24 pages. 4 by 9 inches. Pamphlet 516. 'Flexible Steel Armored Hose'. Illustrated. 28 pages. 4 by 9 inches. Catalogue 321. 'Electric Fans'. Illustrated. 36 pages. 8 by 10½ inches.

COMMERCIAL PARAGRAPHS

T. H. Proske, Denver, recently shipped to the Isthmian Canal Commission the second 25-ft. D 24 Ajax drill sharpener for use on the Panama Canal.

The Hammond Iron Works, Warren, Pa., advises that John M. Nicol has been appointed as its Mexican representative. His office is at 1a Tacuba No. 6, Mexico City.

The Redwood Manufacturers Co., Black Diamond, California, advises that it is furnishing the redwood cyanide tanks for the mill being erected by the Tonopah-Liberty Mining Co., at Millers, Nevada.

Haff & Colwell Bros., Ely, Nevada, have compiled a map of White Pine county, from Government surveys, showing the topographical features, mining districts, wagon-roads, railroads, streams, and postoffices.

One of the largest orders of its kind placed this year, comprising over 1000 cars, has recently been given to the Orenstein-Arthur Koppel Co., whose works are at Koppel, Pa., with a branch office at San Francisco, by the Jamison Coal & Coke Co., Greensburg, Pa. The cars are to be used in the new mines recently opened by this company in the Westmoreland fields. The coal company has been experimenting for several years with all makes of coal cars, with a view to securing actual data relative to the life, maintenance, and transportation costs of the several kinds, and the placing of this order is the result of these experiments. The cars to be furnished are of special design, of all steel construction, with cast steel wheels and roller bearings. Each is to be of 100-cu. ft. capacity.

COALINGA oil production has been threatened by encroachment of underground water. The leading companies have joined in the formation of a committee of eleven to undertake a joint survey and study. This sensible and farseeing co-operation will doubtless save the district from losses amounting to many times the cost of the work.

CONNELLSVILLE coke production, according to the Bureau of Statistics, in April amounted to 1,683,837 tons, a slight decrease from the records for the earlier months of the year. For the first four months of 1910 the production was 7,710,208 tons, almost 80 per cent above the figures for the corresponding portion of 1909. Pig iron production for April, 2,483,763 gross tons, was 43 per cent larger than in 1909 but none the less marked a slight check in industrial activity. The output for the first four months was 10,107,571 tons; 3,000,000 more than in 1909.

FIVE pipe-lines now furnish transportation from the Coalinga oilfield. Two belong to the Standard Oil Company and come to Richmond by way of Mendota; one, belonging to the Associated Transportation Company, leads to Monterey bay; another, that of the Associated Pipe Line Company, extends to Port Costa; and the fifth, the property of the Producers Transportation Company, connects the Coalinga, McKittrick, and Midway districts with Port Harford. Transportation is the secret of development of an oilfield, and in their nearness to the sea the California fields are very fortunate.

SOCIALISM is the next problem in politics. At least so says President Taft. No one can gainsay him, for socialism is an ever present problem. It has been the concern of men ever since they determined to limit their individual wills by becoming social creatures. The first socialist was the savage who gathered some of his fellows into a band knit by ties of common welfare. We will admit that President Taft had a more specific object in view than the inclusion of the general evolution of the social state among the dear concerns of the G. O. P. when he made his recent utterance in Chicago. He was thinking of votes, and of the organizations that pretend to be the exponents of socialism in its narrower and more deformed phases. He was thinking, probably, of a class which is associated in the public mind with the dream of a Utopia or the reaping of harvests which it has not sown. Words mean much. 'Socialism' has acquired an unpleasant flavor, so that men who believe in the practical possibility of a more highly economic and happier social state now describe themselves as collectivists. Under the name of

socialism many of the best things that could be devised for the betterment of human life are included, and this unfortunate association arouses opposition among a host of thinkers who would welcome the effort at improvement if freed from the contamination of an abused term. The thing that warns the healthy minded man away from the so-called socialism of some blatant propagandists is that they present schemes which involve the sacrifice of the individual initiative. A man must not be converted into a machine. He must find closer correlations of his life with those of others, to avoid waste of effort. Whatever will do that, is good, so long as it still leaves the individuals free agents, with opportunity to shape their own courses and utilize the special powers that lie in them. Mr. Taft did not say all this, but we incline to believe that he thought it, and we commend his suggestion, as we would commend that of any political leader who believes that the worthy proposals of the 'socialists' should be saved from hopeless association by being written into the platforms of the parties that have strength to make them effective. Luther objected to letting the devil have all the good tunes, and there is a chance here to rescue some excellent music to inspire the forward march of the race.

SOME TIME AGO 'Mr. Murphy' remarked that copper vacuum was the thing desired in seeking a copper property—'the lower the grade the better'. At the same time the copper-mine promoters have been claiming excessively low costs, present and prospective. It is bad policy. The whole matter was a mistake; the new word going round is that there is no copper vacuum; a tangible quantity of metal is really necessary; and it actually costs enough to mine and smelt it so that no expert accountant is needed to find the item in the published balance sheet of the corporations. In all seriousness, Mr. J. Parke Channing, consistently with previous utterances on the subject which unfortunately have not reached the public, has announced that the costs at Miami will be nearer 9 than 7½ cents per pound. Several copper companies are reported to have the elevation of costs under consideration. The argument is that the prospective buyer who waits in the hope of lower prices may cheer the producers by paying more in the end.

United South Africa

The United States of America must hereafter share with the United South Africa the long cherished initials U. S. A., and will gladly do so. The South Africans have paid us the compliment of adopting in their constitution many of the provisions of our own, and none will more heartily welcome them to the family of nations than do the Americans. In many particulars the formation of the new State is one of the most striking events of current political history. Less than eight years after the termination of a bitterly contested war which resulted in the loss of political independence by the people of two States, the contestants are found joining harmoniously in the launching of a new and larger political union based on the principles of local self-government. In nothing is the greatness of the English people and the sagacity of their political leadership shown more strikingly than in their wise treatment of the Boers since the war, and not less striking has been the far-sightedness of the Boer leaders. We are wont to think of our own as the country of generosity to the defeated, but when R. E. Lee, like Louis Botha, disdained to prolong by guerrilla warfare a contest where the end was certain, his people were met by the horrors and injustice of the long reconstruction period, and now after forty years we have not reached the point that the British have in eight; that of passing over to the defeated, responsibility for the government of the whole country.

The old Boer government was reactionary and corrupt. It laid a heavy hand on the mining industry, and gave little in return. It was inevitable that it should be swept away. The Government since the war has laid equally heavy burdens on the mines, but the money has gone to the Government rather than to favorites, and much has been given in exchange. The greatness of the Boer leaders developed during and since the war, is unchallenged. No one doubts that good and honest administration will obtain with them in charge, and the fine spirit shown by both English and Boers augurs well for the future. The appointment to the position of Governor-General of Lord Gladstone, son of the great prime minister of whose justice the Boers had such signal evidence, was a peculiarly graceful act. An empire of free commonwealths bound by such ties as hold Canada, Australia, and United South Africa together, is one which need have little fear of disunion.

Boosting California

Apology may be in order for the word 'boosting', but no explanation of its meaning is needed. That is the value of the term. It is plain old Anglo-Saxon. It is democratic and is understood. Moreover, it involves the principles of harmony and confidence. The California Development Board, which held its semi-annual meeting at Nevada City last Saturday, frankly called the gathering a convention of boosters. Believing in California as a good place for earnest workers to make money and to get ahead in the world, the members assembled to discuss plans for persistent advertising of the advantages of the Golden State. The California Development Board is a coalition of the former California Promotion Committee, the State Board of Trade, and the California Manufacturers' Association. Numerous local boards of trade and chambers of commerce throughout the State have become affiliated with the new organization, and the effort is being made to co-operate with all such bodies in California.

The place chosen for the meeting was well adapted to draw attention to the diverse opportunities offered by the State. Nevada county has been noted in the annals of mining since the great gold-rush in 1849. It has yielded more than $300,000,000 in the precious metals from placer and quartz mines, and it is still producing about two million dollars per annum. The North Star alone turns out bullion to the amount of a million dollars per year, and its neighbor, the Empire, yields more than half as much, and many other

mines are operating successfully. The great depth of these mines is remarkable. The Empire is hoisting ore from 3000 feet on the incline, while the North Star has explored its vein to a distance of more than a mile below the outcrop. The Champion mine has also reached a depth of 2400 feet. There are few places in the world where gold veins are so persistent, and where the industry is on so permanent a basis. Placer mines are also being worked to some extent, although the anti-débris legislation has tied up the great gravel mines which formerly yielded so much treasure. The deposits of auriferous gravel in Nevada county are of enormous extent, and their gold content is so large that studies are now being made to determine economical means of operating them by modern methods of excavation with machinery. In a few cases it is hoped that dredging may be successfully applied. Opportunity exists for the application of engineering skill and ingenuity in solving the problem of working these great placers without floating the fine sand and silt down the streams to the detriment of agriculture, and of navigation in the Sacramento river.

While Nevada county has won distinction as the banner gold-producing district of California, its agricultural resources are enormous. The fertility of these foot-hill counties is remarkable, and the climate is most propitious. Fruits of every kind, from apples and pears and peaches to figs and oranges are successfully raised. Even the old tailing dumps from the placer mines have in many cases been leveled and converted into orchards. A striking contrast between conditions within a short distance, so often seen in California, is here presented, oranges and ice being harvested in the same month in the same county.

A number of important papers were read. Among these was an interesting account of the mining activity in Nevada county, by Mr. F. M. Miller, and a discussion of the oil industry in California, by Mr. Courtenay De Kalb. The latter is printed in this issue. The suggestion that the United States Geological Survey be given facilities for issuing monthly progress-bulletins presenting the latest observations of the geologists in the field was made the basis of a resolution to be laid before Congress. The value of early information is undoubted, and such bulletins would materially aid the economic development of the oilfields. The Department of Commerce and Labor has filled a need by issuing weekly Consular and Trade Reports, which prove of great advantage in promoting foreign trade. There is no good reason why those who are seeking to open up the natural resources of the country should not equally be facilitated in their efforts by the earliest possible information of geological conditions. We believe that the officers of the Survey would welcome the opportunity to serve the public in this manner if the present restrictions rendering speedy publication of data impossible were removed.

A strong appeal for united effort to secure the endorsement by the Government of the plan to hold the Panama exposition in 1915 at San Francisco was made by Mr. Frank L. Brown, and resolutions were passed pledging the aid of the California Development Board to that enterprise. California has asked merely for official sanction of the fair, and no financial support has been solicited. The sum of $5,000,000 has already been subscribed, a working organization has been effected, and no doubt exists that the people of the State would make it one of the greatest expositions ever held. It would attract capital and bring about a renewal of interest in mining that would prove of lasting benefit. The California 'boosters' do well to insist on the importance of the Panama exposition. It would be the most powerful engine that could be brought into action for promoting the growth of industry at a time when improved transportation facilities will open a new era for the State.

Making Railway Rates

The episode of David Crockett and the coon has been quite outdone by the recent encounter of Mr. Taft and Mr. Wickersham with the railroads. Whereas the famous Tennessean is only credited with scaring one coon into surrender, the Attorney-General has twenty-five railroads to his credit. Not a bad bag for one day's shooting! Even a 'safe and sane' administration, one much 'buttressed about by law' (and by lawyers) can, it seems, be stung into prompt and radical action. Radical it certainly was for the Attorney-General of the United States to initiate injunction proceedings against the railways restraining them from raising rates. It was quite as dramatic as anything happening during Mr. Roosevelt's administration, and almost compensates for the fact that the gun proved not to have been loaded in Manchuria, and for the fuses being wet in Nicaragua. With a little more practice the President may be able to give to Washington press-despatches the old time interest. Once more we may open our daily paper with anticipatory thrills, and again must the anxious calcium man keep the spot-light trained on the White House.

It was a dramatic but easy victory. The railroads were in a false position and so were readily pushed to surrender. Their weakness lay in the fact that they were attempting to rush through a general advance in rates in anticipation of the taking effect of the new law under which all advances must be approved by the Interstate Commerce Commission before becoming effective. Under the old rule railway managers could increase rates whenever and wherever they pleased, subject only to a thirty-days' notice, and the burden of proof as to the unreasonableness of any given rate or advance rested on the protesting shipper. The new law will change this. Before making an advance the railways must satisfy the Interstate Commerce Commission that the proposed rate is proper and reasonable. This accords with the usual rule that persons proposing a change must justify their actions, and it is a just rule. The presumption is that at any rate already established by a railway and under which the latter has been operating, meeting its bills, and paying dividends, is at least not unjust to the railway, and if it be proposed to increase the rate the justification may properly be required in advance. A change in rate affects too many people and unsettles business too widely

to be proper except when clearly necessary. The railways have themselves repeatedly taken this position when decreases in rates have been ordered by State Commissions, and have not hesitated to ask injunctions from Federal Courts restraining State officers from putting new rates into effect. The method used by Mr. Wickersham is one which the railways introduced.

As a result of conference between Mr. Taft and various railway presidents it has been arranged that the railways shall withdraw the offending rates and that the Government shall not prosecute its suit. While this peaceful solution of the difficulty is welcome, it would have been interesting if not profitable to have had the suit pushed, in order to determine whether the raising of rates by 'conference' through the Western Trunk Line Association is in law 'combination in restraint of trade'. As a matter of fact, there is probably no contention but that the Association is a device for the purpose of evading the law. The defense is that the law itself, in making no discrimination between reasonable and unreasonable restraint of trade, is itself unreasonable; a contention that is approved by many outside as well as inside railway circles. However, as the matter now stands, the new rates will be passed on by the Interstate Commerce Commission, and fortunately there is little disposition to question the ability and fairness of the present Commission. In the event of the railways feeling agrieved at any decision they will have the right of appeal to an excellently constituted court.

Whether, as a matter of fact, the proposed increases were justifiable cannot be decided offhand. The railways have been doing an enormous business. For the year ended March 31, 1910, the gross business of 739 roads had increased 15.54 per cent over that for the corresponding previous year, and similar advances had occurred month by month for nearly a year. Not only gross but net earnings have increased. Of twenty roads reporting for the year ended April 30, all but two show substantial increases in the net profit for the year. One, the Fairchild & Northeastern, is an unimportant line, and the only striking exception to the rule was the Santa Fe, which, with an increase of gross earnings amounting to $9,149,782, fell behind $1,522,584 in net earnings. There can be no question that the cost of living has increased for the railways as it has for individuals. It is also true that American rates are low as compared with those of other countries, and that through a long term of years they have been falling. It is further to be remembered that the railways must protect their credit and that they need large sums of money for additional extensions, terminals, track, and equipment. It may even be pointed out that there has been little criticism of railway rates *per se*, but only of one rate as compared with another; that shippers and communities in general have been less concerned with the absolute charge for transportation than with the adjustment of rates so as to favor the community in competition with others. It by no means follows, however, that present rates are too low and the matter demands consideration.

To take the last matter first, it may be urged that, having no agreed basis upon which rates may be made, the only available means for determining the reasonableness of any given rate has been to compare it with existing and unchallenged rates. Presumably if the railways do not lose money by hauling goods at a certain rate in one case, they would not in another substantially similar case. So runs the argument at least, and the absence of a fixed standard has made it necessary to resort to such a means of measurement. While complaint has been mainly as to inequalities in rates there has been none the less a widespread conviction that rates as a whole are not too low. This seems to be based in part on the fact that railway men are unable to defend the present rates except on the basis that they 'move the traffic' and apparently measure the value of the service. This, however, being translated into the popular phrase, 'all the traffic will bear', and keeping in mind the well known fact that the railways have been built for the most part out of the proceeds of bond sales, value being given later to the stocks by the use of surplus earnings, has made the public skeptical as to some of the fixed charges of the railways. Certain notorious cases of manipulation have added greatly to popular prejudice in the matter.

It is exceedingly difficult to determine what the real earnings of American railways have been. Mere addition of surplus and dividends does not tell the tale. Too many ways of hiding or diverting earnings have been in vogue. An elaborate investigation of the Illinois Central, made at the instigation of Mr. C. S. Deneen, who as Governor of Illinois is ex-officio a Director, showed that despite many devices to milk the old main line, the earnings through a series of years had been, not the 8 per cent suggested by dividends, but approximately 20 per cent. Not improbably other roads have done as well or better. A little observation and study will convince any one that American railway managers and owners certainly have made money as fast, and in most cases faster than have their fellows engaging in other lines of business. The periodic talk of the railways being ruined by legislation needs, therefore, to be taken with due allowance. Despite large and frequent injections of water into the stock of the companies, it is now urged, and probably with a large basis of truth, that a physical valuation of the railways would show them to be worth practically the amount of their outstanding securities. Granted that this be true it is undoubted that much of the present value of railways is due to monopoly-value of terminals; in other words it represents at once monopoly and 'unearned increment'. It is a question, and a fair one, to what extent the people should be taxed, and a railway rate in the last analysis is a tax, to conserve to a special group of the people, not perhaps values of this sort already accrued, but similar values accruing in the future. This and similar far-reaching questions must enter into the fixing of railway rates, and it is well that in the future the matter is to be decided by an impartial tribunal rather than practically by one party to the controversy. The duty of each and every one of us is to help keep that tribunal impartial: fair both to the railways and to the public.

The California Oil Industry

By Courtenay De Kalb

*The Golden State has entered the age of oil. From modest beginnings it has risen to pre-eminence. Ten years ago California produced a scant 4,000,000 bbl.; in 1909 her wells yielded 58,191,723; this year it will exceed 75,000,000. During the month of April the output was 6,622,061 bbl., which is at the rate of 80,000,000 per year. Moreover the permanency of the fields is assured for an indefinite period. W. W. Orcutt, the geologist of the Union Oil Co., has estimated that California can maintain its present yield of petroleum for fifty years. This is evidence of the conservative spirit of Mr. Orcutt, for the indications are that the Midway and Sunset fields alone could contribute that amount. It is not the phenomenal flood of oil from the Lakeview and other gushers in those districts that gives color to the claim. There are 255 producing wells in the Midway field, and 10 of those are veritable geysers of oil. The Lakeview has been spouting 48,000 bbl. per day for over three months, until now it has outstripped the best wells of Baku, and holds the record for the world. The significant point is that these wells are so scattered, and have given such evidence of the geological conditions existing there, that 75 square miles of territory may be considered definitely proved. Gushers are not to be looked for in every case; in fact they are not desired; but practically everywhere in this great area reasonable certainty exists of striking oil in the reservoirs overlying the Eocene formation. At the end of the Middle Miocene the rocks were subjected to folding and the general structural features had been determined. The surface was subsequently eroded, and the McKittrick formation laid down upon it unconformably, representing the detritus from the earlier rocks. Thus great irregularities of contour exist: there were valleys and hills covered over by the wash from the anticlinal ranges, and silt was deposited from the lakes, until the depression was fairly well filled. The oil is found chiefly in the deposits immediately overlying the ancient eroded surface. The gushers probably represent 'pools' in the more deeply scored portions of this early land-area; it is as if a canyon had been filled with sand and the oil had then been accumulated in the interstices, but it must be borne in mind that these detrital deposits covered both hill and valley over that old eroded region, and that the oil is held in them throughout their entire extension. No lean streaks have yet been found in the Midway syncline.

Gushers are of two kinds. The flow of oil may be due to gravity, under the pressure resulting from a high head. If porous oil-bearing strata extend from a trough or syncline to a considerable elevation up the leg of an anticline, such a pressure would be developed, just as in the case of an artesian water-zone. The oil would issue as if driven out under hydrostatic pressure. The other form of gusher is due to the expansion of compressed gases accumulated above the oil in a pool. Usually such gushers soon subside as the gas-pressure becomes relieved by the outflowing petroleum. In the Midway district, however, the force seems not to diminish, yet the structure of the district precludes the development of sufficient hydrostatic pressure to account for the phenomenon. The oil-bearing sand in this field is extremely fine in the great area embraced in the syncline. The coarsest will pass through a No. 30-mesh screen, and most of it will pass 80 mesh. This is very different from the coarse oil-sands of the Coalinga district, and the gravelly reservoir under the Kern river field. Except for an enormous force behind it the oil in such small pores as exist in this fine material would be held quite tenaciously, and would issue slowly into the wells. Such a force is found in the gas. As soon as these sands are entered in drilling the gas-pressure is found, and a gas-filled zone extends for 50 to 100 ft. above the oil. In the Buena Vista hills, which represent a later crumpling of the rocks which filled the old basin, the pressure is 600 lb. per square inch. In many of the wells the pressure mounts up to 1000 lb. per square inch, and this is only a fraction of the force exerted by the compressed gas within the rocks. At about this enormous pressure even the lighter hydro-carbon gases become liquid. From this E. A. Starke, of the Standard Oil Co., argues that the gas here does not exist in gaseous form; it is liquefied, and hence force is stored up in such form that it is sufficient to press out the oil for practically indefinite periods. It is worthy of note that no one knows the thickness of the oil-bearing zone in these sands of the Midway field. They have been penetrated only about 10 feet.

Before passing from this interesting field it is well to say a word about the splendid work of the United States Geological Survey. The reports of Ralph Arnold, in co-operation with Harry R. Johnson and Robert Anderson, on the McKittrick-Sunset and the Coalinga districts respectively, have just been published, as Bulletins 406 and 398. They have thrown a flood of light upon the geological situation in general, and will serve as a basis upon which the rock-structure will be more readily determined as data accumulate from further exploration. Mr. Arnold's work is above criticism; he is one of the keenest interpreters of stratigraphy who has ever studied the California oil districts; but everyone is limited by the facts available at the time, and a Government report sacrifies value if not immediately accessible. In the case of an industry which is developing by leaps and bounds like that of oil-production in California the time when a report appears is most important. When the report on the McKittrick-Sunset fields was written the exploitation of the 'Midway flats' had not fairly begun. Mr. Arnold showed acumen in suggesting that the impregnation of the sands might become greater as exploration progressed farther away from the coarser sands of the anticline, but from the evidence at hand he sounded a warning in regard to water. He said, "It has been the experience in analogous structural positions in other localities to find that the water in the beds increases toward the centre of the syncline, and as the Midway Valley is in a general way a great syn-

*Abstract of address at the semi-annual meeting of the California Development Board at Nevada City, California, June 4, 1910.

cline, it is more than likely that the beds underlying it will be found to contain more water than the same beds nearer the edge of the valley." The water-bearing sands were close to the oil-sands high up on the anticline, and the deduction which he made was reasonable, but development in the flats has shown that the oil-sands in the wide trough of the syncline are covered by impervious beds which in the deeper parts of the valley separate the water-sand from the oil-sand by nearly a thousand feet. The U. S. Geological Survey could contribute more in developing the industry if Congress would make it possible to issue results of field work at more frequent intervals. Progress-bulletins, containing the latest field observations, published monthly, would facilitate the exploration of the oil-areas. It is not necessary to await extensive correlation before giving information to the public. The isolated facts would be useful, and misconceptions are no more likely to happen one way than the other. As it is, the people proceed with imperfect knowledge, and risk their money on faith in such indications as are known. The more the Survey can point the way, the better will it be serving the purpose for which it is maintained.

Coalinga claims to be the greatest oilfield in the world, and it well may boast of its splendid production. At the moment it is yielding 55,000 bbl. per day, which is only 5000 less than the Midway. In April it turned out 1,555,561 bbl. It has 20,520 acres of proved oil-land, with 620 wells, which average over 88 bbl. per day. To fully exploit the territory it is estimated that 2800 wells must be drilled. That would indicate an enormous daily potential output. The sands are not uniform either as to their character or as to the gravity of the oil contained in them. Nevertheless the oil-sands are of such great extent that the estimate of 20,000 acres will probably be vindicated, as there has not yet been a dry hole drilled within the proved area. Adjacent territory of promise, but as yet untested, will undoubtedly contribute to the volume of production from this field. The development at Coalinga has been remarkable. In 1902 the field produced only 572,498 bbl.; it rose steadily to 1909, when it stood at 15,079,944, or more than one-fourth of the total production of the State. This year it will exceed 19,000,000. Next to Coalinga comes the Kern field, with 45,000 bbl. per day. The limits of this producing area are also being rapidly extended. In the south the Fullerton-Brea Canyon district is rapidly increasing its output. Last year it yielded 4,271,000 bbl. and other districts in Los Angeles and Orange counties produced 2,000,000, while the Santa Maria, Lompoc, and Arroyo Grande shipped 8,080,488. The possibilities from deep drilling are just becoming shown in southern California, where today one or two wells are a mile deep.

California ranks as the greatest oil producer in the world, and it is a free field, that is, there is a free market. One of the most vital factors is the Independent Agency, which is a combination of a large number of independent producers. It is the effort of this Agency to obtain the best price possible for the oil, while the large marketing companies naturally seek to buy oil as cheaply as they can. The Union Oil Co. is a member of this selling agency, which makes the Independents strong in competition with the Standard and Associated Oil companies. The latter represents the oil interests of the Southern Pacific railroad. The area controlled by the Southern Pacific is enormous, making it probably the largest single holder of oil-lands in the country. This arose from the granting by Congress of a land subsidy in the form of every alternate section. It is the existence of this ownership of alternate sections that is responsible for the hostility of the people toward the proposed legislation authorizing the Government to withdraw oil-lands from location. It would not result in conservation evenly and equitably applied. The lands of the Southern Pacific are patented, and production could continue upon them. To a certain extent adjoining Government lands would be drained. The argument is fair, though it should not be pressed too far. A well will usually not exhaust more than five or six acres, and sometimes not that much. The viscosity of the oil prevents a freer flow, and capillarity holds it back. Nevertheless a considerable percentage of the national reserves might suffer depletion. In the Kern field the practice of the Associated Oil in drilling lines of holes along the boundaries of its land is conspicuous. These rows of wells capture something from the neighbor who does not meet them with opposite drill-holes, and it also keeps the Associated lands from being drained by wells on adjacent property. Withdrawals might properly be made on unsurveyed lands, or on such portions of the public domain as are not affected by the railroad land-grant. It need hardly be urged that retroactive legislation is and always has been repugnant to the sense of right and justice in the people. It seems that there is no restraint in the Federal Constitution against the enactment of a law which would not only validate the withdrawals already made, but would place a bar to patent upon locations entered prior to the withdrawals; but Congress can ill afford to permit interference with a vested right when acquired in due compliance with existing statutes, even though it may not possess the finality of letters patent. The case would be the more aggravated if it should be allowed to operate to the detriment of individuals in contradistinction to the advantages which would be given in certain areas to a great corporation whose holdings were also acquired through Act of Congress. In any event a man should be protected in what he has legally acquired. If it be contrary to the public welfare that further locations of public land be made, no one could protest that he had been wronged by a legal general withdrawal of that privilege. Common law right is common sense justice, and the common sense of mankind rebels against retroactive legislation.

The market for oil is constantly widening. A few years ago coal was a competitor of oil on the Pacific Coast. Today crude petroleum has monopolized the field as a fuel except for domestic heating. Even in private houses the oil-furnace is coming into use. The cost of oil at the wells is frequently stated at 50c. per bbl. In 1908 the Government figures showed

52c. realized in California, which was the lowest of any State except Oklahoma and Kansas. In Pennsylvania it was $1.79 per barrel, though of a higher average quality. At the present time, taking into consideration the deliveries at low prices under old contracts, the average paid at the well is probably not more than 40c. Adding a pipe-line charge of 20c., a selling charge of 5c., and another 20c. for local distribution, the cost at tide-water does not exceed 95c. This makes California fuel oil approximately equivalent to good coal at $3.50 per ton. There is a further economy in the labor of firing, cleaning furnaces, and waste in handling, together with the more perfect utilization of the heat-value of the fuel. About 72% of the oil output of the State is used for fuel.

The facilities for distribution are also excellent. The Producers' Transportation Co. is operating an 8-in. pipe-line 210 miles to Port San Luis, serving the Sunset, Midway, Kern, and Coalinga fields, transmitting 20,000 bbl. per day. The Associated Oil Co., serving the same fields, operates one 8-in. pipe-line 350 miles to Port Costa, on San Francisco Bay, and a 6-in. line, 108 miles long, to Monterey. The Standard Oil, drawing from the McKittrick, Kern, Midway, and Sunset fields, transmits 35,000 bbl. per day to Point Richmond, 315 miles, through an 8-in. main. There are 21 pumping stations on this line. Oil for piping is heated to 180°F. by exhaust steam from the pumping engines. The friction of the heavy oils, which registers about 15° Beaumé, is reduced fully 90% by this elevation in temperature, each 10°F. corresponding to about 1° Beaumé in gravity. The cost of these pipe-lines, with all accessory equipment, has averaged about $10,000 per mile. Other lines contemplated are one from the oil districts of Kern county across the Tehachapi pass to Mojave, which seems necessitated to relieve the heavy traffic on the single-track railroad over these mountains, congested as it is by the joint use of the Southern Pacific and the Santa Fe. The Independents are also projecting a pipe-line to Arizona, which would serve the six railroads in that territory, as well as the copper districts of Globe, Miami, and Douglas, and the works of the Cananea Consolidated Copper Co. across the line in the State of Sonora, Mexico.

The consumption of oil on the Southern Pacific system west of El Paso and Sparks and south of Ashland amounts to about 9,000,000 bbl. per annum. In April last the oil burned on this system was 746,000 bbl. The locomotive mileage was 2,651,950. distributed as follows: freight service, 905,150 miles; passenger, 1,295,608; switching, 327,164; work train, 106,540; construction, 17,508. This shows a duty of 0.28 bbl. of oil of about 16° Beaumé per locomotive mile. During the period of nine months ended March 31, 1910, the duty was 16 gallons of oil per locomotive mile in freight traffic, and 8¼ gal. in passenger service. The locomotive boiler-pressure averages about 190 lb., and the efficiency obtained gives an equivalent of 163 gal. of oil to 2000 lb. of coal, or a trifle less than 4 bbl. of oil equal to 1 ton of bituminous. The efficiency varies considerably with the type of locomotive. The 8-wheel type gives an equivalent of 144 gal. to a ton of coal, the 10-wheel class, 151 gal., the 12-wheel wide fire-box, 158 gal. The mean equivalent of 745 engines is 152½ gal., or 3.58 bbl. of 42 gal., equal to 1 ton of coal. The new Mallet consolidated compound freight engines show an equivalent evaporation of 15.04 lb. of water per pound of oil, with a boiler efficiency of 78.52%. Otherwise expressed, 29.51 gal. of oil will haul 1000 tons 1 mile, or 1 lb. of oil will perform the duty of carrying 3.15 tons 1 mile. It has been said that the increased profits of the Southern Pacific, which have raised it from non-dividend paying to one of the best paying railroads in America, represent the economy resulting from the use of oil instead of coal as fuel. This may be an exaggeration, but there is enough truth in it to typify the great industrial importance of the utilization of crude petroleum for generating power. It has given fresh vitality to California and to great areas in the West. California oil goes to British Columbia, to Alaska, to the Orient, to Panama where the work is being done with the power developed from it, to every Pacific port in South America even as far as Punta Arenas on the Straits of Magellan, and the demand, domestic and foreign, is growing as fast as the fields can be developed. There are 6692 producing wells in the State at the present time, which correspond to an area being drained which does not exceed 33,460 acres. This is based on the fact that each well will produce from only about five acres. The proved area in the Midway field was 75 square miles, or 48,000 acres, and in the Coalinga field, 20,000. These are but two fields, and only a fraction of the possible productive area which may yet be proved in them. The other fields swell the total to an acreage so great that the land actually producing today is but a small portion of what is known to be available.

While ultimate exhaustion is certain, the danger is remote; the industry is a safe one. It is being capitalized as befits a safe and permanent industry. The exact amount of capital invested in the California oil industry as a whole is difficult accurately to estimate. It costs perhaps about $6000 per acre to drill and equip the wells, which gives a total invested in wells alone of $100,000,000. The pipe-lines represent about $10,000,000; the Point Richmond refinery cost nearly $5,000,000; other refineries, tankages, cars, ships, and the like, swell the figure for accessories to at least $50,000,000. The land being drained by wells would have an average value of $2000 an acre, or $60,000,000. This gives a grand total of $210,000,000. The output of 79,000,000 bbl. per year at 40c. is worth $31,600,000. Half of this is available for dividends, which would indicate that the oil industry as a whole was earning 7½% on the invested capital.

The California Oil Fields, Ltd., a British corporation, operating in California, produced last year 4,378,464 bbl., against 3,563,679 in 1908, 3,242,942 in 1907, and 2,512,655 in 1906. The production for the entire State of California in the same years respectively was 58,000,000, 48,000,000, 40,000,000, and 32,500,000 bbl. Operating profits of the California Oil Fields Co. in 1909 were $886,365, while dividends of 35% were paid. The California company sold its product principally to the Standard Oil Company.

Prospecting, Developing, and Mining

By R. W. Brock

*If the question were put to the members of this Institute, what is the most serious hindrance to the development of the mining industry of the country, they would, no doubt, unanimously reply 'wild-catting'. Money that should be invested in the development of the resources of the country, swells the profits of brazen and unscrupulous promoters; and the victims who would otherwise have become financial supporters of legitimate mining, pocket their losses, remarking that having bought their experience of mining, they will in future be careful to abstain from engaging in so risky a pursuit. The honest promoter, who will not make false statements or rash promises, finds it difficult or impossible to get money for his legitimate projects in competition with the glib fakir who is unhampered by considerations of conscience or fact. If 'wild-catting' is such a millstone about the neck of the industry, it is fitting that the Institute, whose chief aim is to promote the welfare of mining, should take steps to eradicate the evil; and that men, more especially mining engineers, whose interests are so closely identified with the industry, should do everything possible to discourage this evil practice.

While the mischief of 'wild-catting' is well recognized, it is not so easy to determine how to prevent it. The panacea is not to be found in protective legislation, although the laws might, perhaps, be made more effective. Possibly, however, the remedy lies in educating the public. This is a work that might well be undertaken by this Institute. The public must be instructed in that science, which may, for want of a better term, be called 'mining embryology'. At present, even in law, where fine, not to say hair-splitting, distinctions are supposedly drawn, any claim is termed a mine; any claim-holder, a mine-owner; any prospecting, mining. This looseness of definition and wrongful use of terms merely makes worse confounded the confusion in the mind of the layman. If, then, the public were taught to draw sharp distinctions between the meaning of the words prospecting, developing, and mining, an important step would have been taken toward rendering 'wild-catting' ineffective. For the result of such teaching would be an early realization of the fact that of many thousand claims in a district, only a limited number rise to even the dignity of prospects, while of the prospects but a score or so will ultimately develop into mines. Having this knowledge the public then will be in a position to recognize as a 'wild-cat' a claim or a prospect that is being offered or promoted upon the representation that it is a mine. Some fear that if the uncertainties in connection with the business of mineral development are too freely indicated to the public, this course would have a tendency to discourage the investment of capital in such undertakings. But this point of view is quite untenable. Frankness in this respect would inevitably be beneficial in effect. It is true it might deter the small investor, who can ill afford to risk his savings, from engaging in mining ventures; but such a result could not be regrettably regarded. Thus, were the public capable of forming a correct estimate of what may be referred to as the relative probabilities in mining, the distinction as between 'actual mining operations', 'development operations', and 'prospecting operations' would become readily apparent. Mining investment would then rank with and be regarded as equally safe as investment in other industrial undertakings, and this would necessarily have a stimulating rather than a depressing influence on investment included in the former class. Again, neither development companies nor the promoters of legitimate undertakings of this character would experience greater difficulty in securing capital to carry out their projects; for the public would be quick to grasp the exceptional opportunities afforded by ventures of this description.

Large profits are the exception in mining. The price paid for a mine or for mining stock usually represents the full value of property, and provides only for a fair margin of profit in addition to the return of the original capital invested; for there can be no reason or occasion to offer for sale a property below its intrinsic value as so readily determined from available data in respect of the developed ore and the costs of extraction. Hence, when fortunes are made in mining, it is usually by those who engage in 'development' enterprises. Here, of course, one must be prepared to reckon with the element of chance; but this in itself is not a deterrent to enterprise. A man accepting a risk with his eyes open is, if unsuccessful, in a different position to one whose loss or failure is attributable to the misrepresentation of others, or to his own misconceptions. Further, knowledge such as indicated will prevent the investor from paying for a prospect a price far in excess of its value: it will impel him to require that such capital as may be subscribed toward the prosecution of an undertaking in which he embarks be devoted strictly to that purpose; he will, furthermore, require to be satisfied that any development company with which he associates himself is provided with adequate capital with which to acquire and test, if need be, a number of prospects; and he will also insist that the best technical advice is secured in carrying on investigation and operation in connection with the undertaking. Under proper conditions, then, well organized and properly directed development companies would have every prospect of succeeding; and enterprises of this nature should afford a peculiarly promising and attractive outlet for the investment of capital in Canada.

The only individual likely to suffer by the education of the public is the unscrupulous promoter, whose welfare need not be a matter of concern. If his means of livelihood be taken from him, so much the better. Industrial conditions would thereby be so much the more improved; for if but twenty-five per cent of the money now misspent in the purchase of so-called mining stock were available under the

*Abstract of paper on 'The Necessity of Distinguishing Between Prospecting, Developing, and Mining', read before the Canadian Mining Institute.

conditions suggested, it is certain that the actual development and expansion of the industry would be greatly accentuated. Mining engineers are not wholly concerned in money making. They are equally interested in the establishment, on a sound and worthy basis, of the industry with which they are associated. To educate the public to a more sensible and better understanding standpoint of the nature of the industry, to direct money, now wasted in foolish or fraudulent schemes, into needed channels for the development of the mineral resources, if not a duty, is, at any rate, in keeping with the ideals of the profession. It is, therefore, urged that mining engineers, both as individuals and as a body, engage in an endeavor whereby they may at once benefit themselves, stimulate the industry, and perform a much-needed public service.

COST OF DRILLING

The figures given below cover the cost of prospecting for copper at Miami, Arizona, according to William G. Weber, as published in *Engineering-Contracting*. The data are based on an assumed average life of four years per machine. A drilling machine with tools sufficient to operate for that length of time would cost about $6000. The minimum amount of road required per hole is about 300 ft. When holes are drilled at 400 ft., 600 ft., or greater intervals, the item of roads becomes correspondingly greater. On the fairly steep slopes (20°) encountered in the Miami district, 75c. is an average cost per foot of road.

COST OF DRILLING

	Cost per ft. of hole.	
Labor—		
2 drillers at $6 per day	$0.48	
2 helpers at $4.80 per day	0.38	
1 sampler at $4 per day	0.16	
1 foreman at $6 per day (2 machines)	0.12	
	$1.14	$1.14
Roads—		
Labor at $2 per day	$0.50	
Foreman at $4 per day	0.05	
Powder, caps, and fuse	0.03	
Tools, etc.	0.01	
	$0.59	$0.59
Coal, coke, oil, etc		$0.27
Water		0.10
Teaming		0.10
Assaying, office, and incidentals, etc		0.16
Interest at 5% and depreciation		0.20
Total cost per foot of hole		$2.56

The monthly average of the cost per foot of hole drilled varies with one company from $2 to $3. In another instance, where holes are drilled farther apart and the drilling is poorer, the cost per foot has run as high as $5. When drilling is the only means of development being used on a property, the cost of camp maintenance and incidentals considerably swells the cost account. It would hardly be fair, however, to charge these items up to drilling when a comparison with other districts is being made.

Export of tin from Penang, Straits Settlements, during the month of February was 1820 tons as against 1750 tons in February last year.

A Bit of History

By Charles G. Yale

In the early days mining assessment 'ads' were the main source of income for the M. & S. P. At one time we came very near losing the business. The *Alta California* was the most important daily paper in San Francisco then, and had a good part of this advertising. There was considerable rivalry to get it. Our prices in the weekly were, however, less than those on a daily, so we obtained a good share. Finally the *Alta* people formed a plan to cut us out altogether, and got some of their political friends to present a bill to the legislature providing that all mining assessment and sale notices should be printed only in papers of 'general circulation'. The Mining and Scientific Press did not then come under that heading.

The members of our firm paid but little attention to the progress of the bill at the legislative session and the first thing they knew it had passed both Houses and had been sent to the Governor for his signature. Had this bill become a law it would have taken away half the profits of our advertising columns. Dewey and Ewer both dodged the task of talking the Governor over to our side, as no opposition had been shown to the bill, and, as stated, both Houses had passed it. I was then sent up at this late hour to try to get the bill 'killed'. My old friend Albert Hart happened to be private secretary to Governor Newton Booth, and I went at once to him to arrange an interview with His Excelleney, not an easy thing to do in those last days of the session. He did this nicely, and I got an interview ahead of half a hundred waiting suitors. What was more to the purpose, Mr. Hart gave me the 'tip' on which I eventually won.

The proposed law, it happened, would benefit the *Alta* only, no other paper then carrying these particular 'ads'. It seems that the proprietors of the *Alta* had not been at all friendly to the Governor during his election campaign, and I had a good argument to begin with. Mr. Hart had the particular bill placed on top of the file ready for the Governor's signature and ready at his hand. By pre-concerted arrangement I was ushered in at an opportune time, and Mr. Hart introduced me to Governor Booth. I, as briefly as possible, told him of the object of the bill, and how it would injure badly a paper devoted to the mining interests of the State, and benefit only a single newspaper, the *Alta Californian*. He had not yet read the bill, but asked Mr. Hart for it, read it, asked me a few incisive questions, and dismissed me with no promise except that he would look into it further before signing. He never did sign it, and it, therefore, never became law. The *Alta* people never knew how their pet measure, carried so safely through both Houses, had been pocketed at the last minute, or what influence caused this to be done. It was not until daily mining-stock papers began to be published in this city that the volume of this class of advertising dropped off in the Mining and Scientific Press and at the same time other sources of revenue were developed.

Efficiency of Centrifugal Pumps

By F. W. KERNS

The efficiency of any machine is $\frac{\text{output}}{\text{input}}$. If P be the power put into a pump; H_2 the total external head the pump overcomes, including all friction head and the velocity head of final discharge, for which latter the pump should be given credit, as it is impossible to deliver water with no velocity; Q the cubic feet of water delivered per minute; w the weight of a cubic foot of water; and E the efficiency; then $E = \frac{QwH_2}{550} \times \frac{1}{P}$.

Referring to Fig. 1, let H_1 be the total friction head above the pump; h_1 the total friction head (including entry head) below the pump; $H + h$ the total gravity head; and $\frac{V_1^2}{2g}$ the velocity head of final discharge.

Then $$E = \frac{Qw}{550}\left(H + H_1 + h + h_1 + \frac{V_1^2}{2g}\right) \times \frac{1}{P} \qquad (1)$$

To obtain the term within the parentheses, let a pressure gauge G, be tapped into the pump close under the discharge flange so as to indicate the conditions at the point of discharge of the pump proper, and the reading (in feet of water) corrected by adding the vertical distance between the point of tapping and the centre of the pump, or by piping the gauge down to the level of the pump centre. Also let a vacuum gauge g, be tapped into the suction elbow, level with the centre of the pump and close against the casing flange, as the suction elbow is sometimes replaced by a straight horizontal suction pipe, and cannot therefore be considered an integral part of the pump nor its friction loss charged against the pump. If now the supply surface remain at a fixed elevation and continuity obtains, the following energy relations may be written.

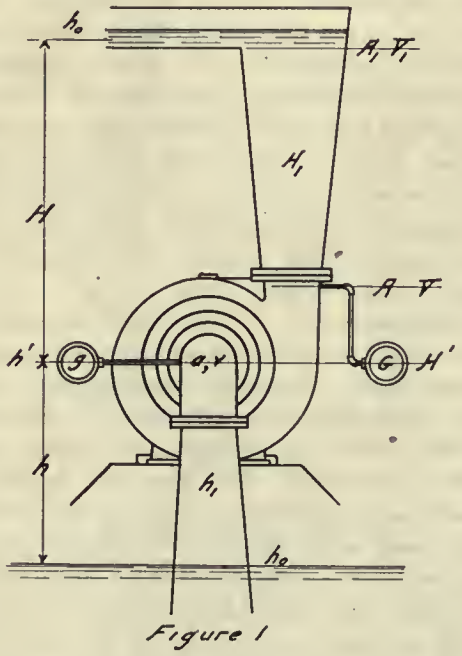

Figure 1

Below the pump, at the surface, the total energy is that of atmospheric pressure, h_0; and at the level of the pump centre, the total energy is that of absolute pressure (pressure above zero), h'; elevation, h; heat, h_1, due to friction; and velocity, $\frac{v^2}{2g}$; or writing the energy equation, $$h_0 = h' + h + h_1 + \frac{v^2}{2g} \qquad (2)$$

Above the pump, at the level of the centre, the energy is that of absolute pressure, H_1, and velocity, $\frac{V^2}{2g}$; and at the point of final discharge, the energy is that of elevation, H; heat, H_1, due to friction; atmospheric pressure, h_0; and velocity, $\frac{V_1^2}{2g}$; or the energy equation is $$H' + \frac{V^2}{2g} = H + H_1 + h_0 + \frac{V_1^2}{2g} \qquad (3)$$

Transposing and adding (2) and (3)

$$H' - h' = H + H_1 + h + h_1 + \frac{1}{2g}(v^2 - V^2) + \frac{V_1^2}{2g} \qquad (4)$$

But the gauge reading $G = H' - h_0$; and the gauge reading $g = h_0 - h'$; and adding, $G + g = H' - h'$. Substituting in (4), and deducting $\frac{1}{2g}(v^2 - V^2)$ from both sides, $G + g - \frac{1}{2g}(v^2 - V^2) = H + H_1 + h + h_1 + \frac{V_1^2}{2g}$. Substituting in

$$(1),\ E = \frac{Qw}{550P}\left[G + g - \frac{1}{2g}(v^2 - V^2)\right]$$

But for continuity, $Q^2 = a^2v^2 = A^2V^2$, where a and A are the areas of opening corresponding to v and V respectively, and from this, $v^2 = \frac{Q^2}{a^2}$ and $V^2 = \frac{Q^2}{A^2}$, so finally, $$E = \frac{Qw}{550P}\left[G + g - \frac{Q^2}{2g}\left(\frac{1}{a^2} - \frac{1}{A^2}\right)\right]$$

The term $\frac{1}{2g}(v^2 - V^2)$ or $\frac{Q^2}{2g}\left(\frac{1}{a^2} - \frac{1}{A^2}\right)$ disappears in case $a = A$, that is, if the suction and discharge openings of the pump are the same size. Where they are

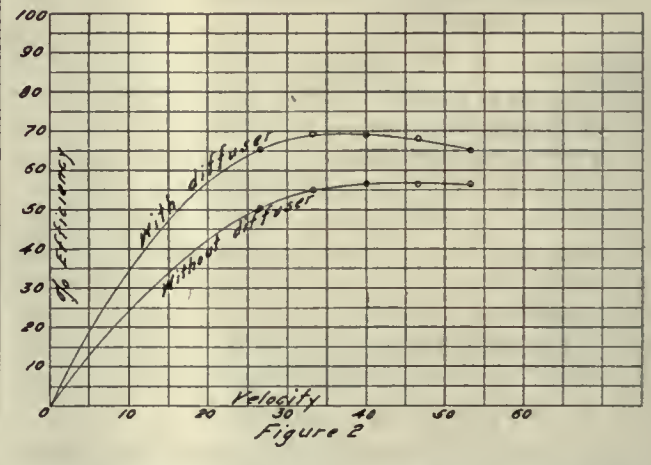

Figure 2

not, this term must be considered as a correction to the observed gauge readings; for if the runner be removed and water forced upward by other means or allowed to flow backward through the pump, there will be a difference in the two gauge readings due to the difference in the velocities through the unequal openings, even though the pump be thus entirely eliminated. When a shaft extends through the suction elbow, its area must be deducted from the area of the elbow opening, when determining a.

The above result may be reached more directly by considering the pump as introducing energy into

the water; thus the energy immediately below the pump, using the same notation as before is $h' + \frac{v^2}{2g}$; and immediately above, properly neglecting friction within the pump, $\frac{v^2}{2g} + H'$. The difference, $H' - h' - \frac{1}{2g}(v^2 - V^2) = G + g - \frac{1}{2g}(v^2 - V^2)$ must be the total energy head, H_2 introduced or overcome by the pump; which agrees with the result obtained above.

It is to be noted that the above method of measuring the efficiency credits the pump with any 'diffuser' effect introduced by placing a cone above the discharge to reduce the velocity head of final discharge or the pressure H' against the pump. Fig. 2 shows the results of tests made on the efficiency of a pump with and without a diffuser. In this case it is seen that the diffuser increased the efficiency of the system by 12 per cent.

ASSAY OF GOLD-SILVER CYANIDE SOLUTIONS

By Theo. P. Holt

Many methods have been published for the determination of gold and silver in cyanide solutions, which with proper care will give reliable results. Most of these, however, fail to meet the requirements of speed, accuracy, and a minimum of attention, desired by the cyanide chemist. In general they require three operations: (1) a precipitation or evaporation of the measured solution; (2) a fusion or scorification of the product, and, (3) a cupellation of the resulting lead button. The second operation is obviated by modifications of Chiddey's well known method, and the schemes outlined by William Magenau* and Mr. Barton† under most conditions are very satisfactory. In connection with experimental work at the Utah School of Mines and elsewhere, I have had occasion to test these methods on a large variety of solutions. I find that it is best to omit the zinc dust entirely and precipitate the precious metals along with the sponge lead on a square of aluminum foil. Because of the position of aluminum in the electromotive series of the metals, it is a more effective precipitant in an acid solution than zinc. It also readily replaces lead from solution, the lead forming a convenient collector for the small amount of gold and silver present. The process as outlined below permits of direct cupellation, is reliable, and requires little attention.

Take from 5 to 10 assay tons of solution in a beaker, place on a hot plate and heat almost to boiling. Add from 15 to 20 c.c. of a saturated solution of lead acetate, a 1½-inch square of aluminum foil, and 10 to 15 c.c. of strong hydrochloric acid. A heavy white precipitate of lead and silver chlorides appears at this point, but passes again into solution as the metals are deposited. Leave the assay on the hot plate until the solution clears up and the lead sponge has all collected on the aluminum. Decant the solution, pressing the water out of the lead sponge with a rubber tipped stirring rod, and transfer the assay to a 2½-inch square of lead foil. Take out the aluminum square, which will be found to separate readily from the lead, and roll the sponge with a round bottle to free from moisture. Fold up into a convenient form and drop into a hot cupel. The aluminum sheet should be $^1/_{16}$ inch or more in thickness, otherwise small pieces may become detached and remain with the lead sponge, causing the cupellation to spit. The assay requires very little attention. The re-agents are all added at one time and while the sponge may be ready for cupellation in 20 minutes, it may remain for an hour or more should the assayer be busy with other work.

I have tested the method on a large variety of solutions, and find that the losses are less than commonly occur in cupellation. A few examples from my notes may be of interest here.

No.	Solution assay. Au (mg.)	Ag (mg.)	Residue loss. Au (mg.)	Ag (mg.)
1A	0.17	5.19	0.00	tr.
1B	0.165	5.18	0.00	tr.
2A	0.845	25.15	0.00	tr.
2B	0.835	25.14	0.00	0.06
2C	0.85	25.07	0.00	0.04
2D	0.84	25.38	0.00	0.06
2E	0.84	25.09	0.00	0.04
3A	1.73	50.56	0.00	0.05
3B	1.73	50.62	0.00	0.00
3C	1.71	50.20	0.00	tr.
3D	1.69	50.47	tr.	0.56

The above assays were made on pipette measurements of a standard solution. The residue loss was determined by a fusion on the evaporated solution and the aluminum foil. The loss during cupellation varied from one to two per cent, but since it effected the assays much alike it does not appear in the results.

AUSTRALIAN MINING REGULATIONS

An act for the regulation of coal mines, passed by the Australian State of Victoria, has recently come into operation. It also authorizes the establishment of State coal mines. John F. Jewell, U. S. Consul at Melbourne, outlines its provisions as follows:

The State mines may be opened by the mines department, but when so opened up must be handed over to the railway commissioners to be worked. One of the most important provisions of the new act is that providing for the 'bank to bank' principle, which provides that "no person shall be employed below ground in any mine for more than eight consecutive hours, inclusive of 30 minutes as meal time, or for more than 48 hours in any week, except in cases of emergency." After stating that an interval of at least eight hours shall elapse between "one period of being below ground and the commencement of the next," the law states that "a person shall be deemed and is hereby declared to be employed below ground in the service of the owner of the mine, within the meaning of the act, from the time that he commences to descend the mine until he returns to the surface." A short time ago an extensive coal deposit was discovered a short distance from Melbourne. This mine is being opened up by the mines department and when a railway to the field is completed in March will be managed by and for the State Railways.

Tourmaline in California

By John L. Cowan

Offieial statisties of Ameriean gem mining place this industry almost in a ridieulous light, giving the value of the produet at somewhere in the neighborhood of $300,000 annually. It is believed that there is more than one Ameriean gem mine that produees gem materials of a greater value, just as they eome from the ground, than is credited to all the gem mines in the eountry. This discrepaney between facts and offieial figures is not due to any lack of diligence on the part of representatives of the Geologieal Survey, but must be attributed to the refusal of the gem-mining companies to give out aeeurate information, or, in some eases, to supply any information at all. They fear that statisties showing the real magnitude of their output would eheapen the produet: that if the publie were informed as to the large quantities of eertain gem materials that are taken from the ground annually, it would expeet to buy them at mueh lower priees than now prevail. The same fear that the people will get to know too mueh leads most gem miners to make of their mines 'dark secrets', so that visitors are unweleome, and pieture taking sternly interdieted. It is not at all ineoneeivable that a more liberal policy on the part of the gem produeers would be rewarded by more liberal treatment at the hands of the people. The American public likes to buy things that it knows something about; and if American gems are ever to beeome popular it will be necessary that the produeers gratify a legitimate desire for information as to where they eome from and how they are obtained.

The three leading gem materials produeed in this country are sapphire, turquoise, and tourmaline. Probably the greatest sapphire mines in the world are located on a branch of the Judith river, in Montana, but the output is all shipped to London to be eut, and no reliable information is ever given out as to the amount. The largest of modern turquoise mines are operated in New Mexieo and California; and the world's greatest tourmaline mines are located in San Diego county, California, but seereey is maintained as to the amount and value of the output. It may be perfectly true that this is the business of no one but the mine owners, but too mueh mystery is not eondneive to popularity. Several years ago George F. Kunz, of New York, America's most famous gem expert, stated that it was quite possible that California might soon be known as one of the greatest gem-produeing countries in the world. He pointed out that the tourmaline, spodumene, rock crystal, and other gems of the State have been better known to the people of Russia, Spain, Germany, and other countries of Europe than to Californians and that these gems are better represented in great museums of New York, Washington, London, and Paris, than in the State Mining Bureau of California, or the State University at Berkeley.

The most beautiful of all California gems is the tourmaline, pronounced by Max Baner, the celebrated German mineralogist, to be the gem that most nearly resembles the diamond. It is only within reeent years that tourmaline has been used to any extent in this eountry by jewelers, and even yet it has not reaehed the popularity to whieh its beauty, its rarity in nature, and the low priee at which it sells (as eompared with other gem materials of inferior merit) entitle it. Not even the diamond exeeeds in beauty the carefully eut and appropriately mounted gems of this variety sometimes seen in rieh shades of pink, ruby-red, and blue, selling at a fraction of the cost of stones of far smaller merit.

The original diseovery of tourmalines in California is said to date baek to 1872, when several speeimens were found on Thomas mountain, in Riverside eounty. The Columbia gem mine was later located near the spot where these stones were found, but development has been hampered by litigation. Other diseoveries have been made from time to time in the San Jaeinto range, and a number of mines have been opened. Most of the speeimens shown in the windows of loeal jewelers and lapidaries, of opaque pink tourmaline embedded in the roek, with a large number of small erystals radiating from a common eentre, eome from the Pala distriet, in San Diego eounty. Years ago an Indian named Vensuelada called the attention of white men of the neighborhood to the peeuliar formation, and soon thereafter an old miner and prospeetor named Henry Magee loeated the property as a quieksilver mine, thinking that the pink erystals must be einnabar. He sent samples to various ehemists, none of whom were able to identify them, although they assured him that they eontained no traee of quieksilver. He abandoned the elaim, but it was not long until it was again loeated by Don Tomas Alvarado, a Mexiean ranehman, who eoncluded that the odd-looking pinkish, bluish, and gray rock formation, studded with small pink erystals, must be a peculiarly ornamental variety of marble. He sent many speeimens to mineralogists in various parts of the eountry, endeavoring to find out what his new building material was worth. Some of Alvarado's speeimens passed into a private colleetion in New York. Here they attraeted the attention of a visiting German mineralogist, who was familiar with the lithia mines of Europe, and was struek by the similiarity of the undetermined speeimens to certain lithia-bearing ores. He obtained a speeimen for analysis, and was then able to state authoritatively that it was as rieh in lithia as any known in the world. The mine is now controlled by the American Lithia Co., of New York, and is an important produeer, but no tourmaline erystals of gem quality are obtained from it. However, speeimens are highly prized for mineral eabinets, and for that purpose have been sent to all parts of the eivilized world. Other mines have been opened in the same region, notably the Stewart, Pala Chief, Tourmaline Queen, and Naylor-Vanderburg, yielding both tourmaline and kunzite.

Eighteen miles to the southwest of Pala is the mueh more important gem-produeing distriet of Mesa Grande. This loeality is most eonveniently reaehed from San Diego, the San Diego & Cuyamaea railroad running baek 25 miles to Foster, and a stage line from that point, through Ramona, extending 33 miles to Mesa Grande. Numerous elaims have been located in the hills surrounding Ramona. Some of

these have yielded fine gems, but none have been developed sufficiently to determine their value. At Mesa Grande are the Himalaya and the San Diego tourmaline mines, and a number of prospects. Accounts of the discovery of the Himalaya mine differ. Crystals have been found in Indian graves of the neighborhood of great antiquity. It is generally supposed that these came from the site of the Himalaya mine, but this is uncertain. About 30 years ago some Indian children picked up several beautiful blue six-sided crystals, and from time to time cowboys and others found similar objects in the neighborhood, particularly after heavy rains that washed away the sand and clay, exposing the shining crystals to view. Then the children of the Mesa Grande school fell into the habit of frequenting the locality to look for the baubles. These were found in all sizes, some no larger in diameter than a slate pencil, and some two inches or more across. Many were nothing but quartz crystals, clear and transparent, but others exhibited beautiful shades of pink, red, blue, and green. Sometimes the boys sold particularly fine specimens to the school teacher, or to tourists stopping at Rancho Cereza Loma (a summer resort five miles away from where the bright stones were found), and in the end some of these fell into the hands of some one acquainted with their true nature. About twelve years ago, an agent of Lippman Tannenbaum, of the Himalaya Mining Co., of New York, located the claim. Since then development has proceeded steadily until the Himalaya tourmaline mine now ranks among the world's greatest gem-producing properties, and is recognized as the greatest tourmaline mine that has ever been discovered. The variety, beauty, and value of the gems found here are such that Mesa Grande is sometimes called the 'Kimberley of America'. For several years, surface or bench digging was followed exclusively, but the overburden of rock and earth became too great for removal at a reasonable cost, and was subject to slides and cave-ins in the rainy season, so that underground work was resorted to. An adit has been driven into the hill for several hundred feet, following the gem-bearing vein, with several lateral branches, also in the vein. The following description of the formation is abridged from Bulletin No. 37, of the California State Mining Bureau: "Both hanging and foot-walls are of hard blue diorite, and the ledge is of fine crystallized pegmatite, dipping from 26 to 33 degrees southwest. The upper pegmatite is usually stained with lithia and manganese, and large masses of lepidolite are associated with tourmaline. The pockets are large, and filled with talc and hydrous micas, in which the gem crystals occur embedded, many showing peculiar etchings. . . . Among the minerals noted were orthoclase, albite, lepidolite, amblygonite, small clear pieces of spodumene, muscovite, tourmaline (black, green, blue, deep red, and rose), pink and aquamarine beryl, hornblende, and epidotic rocks, spessartite, and essonite garnet, large and very transparent quartz crystals, talc and hydrous micas, and a dark brownish transparent crystal, which has not yet been determined".

No other tourmaline mine in the world has ever yielded crystals at all comparable in beauty and value with the finer specimens obtained from this wonderful mine. Many are transparent, of the finest gem quality, in perfect prisms, singly or doubly terminated. Pink is the predominating color, but many specimens are found in matchless ruby-red, green, and blue shades. Some are parti-colored in two or more sections, the different colors being sharply separated so that gems of ordinary size may be cut, one-half being pink and the other green or blue. In some specimens the color arrangement is still more remarkable. In the interior will be a core of green, surrounded by a thin layer of white, and this in turn enclosed in red. Brazilian tourmaline crystals showing a concentric arrangement of colors have long been known, but in these the red portion is in the centre, and the green on the exterior.

Operations in the Himalaya mine are remarkably simple. All the vein material is taken from the underground workings in ordinary mine cars, conveyed to the washing plant, where it is thoroughly washed for the removal of talc and mud which might obscure the gem materials and prevent their detection. Large nodules and crystals are easily picked out, but the entire mass must then be carefully sorted over by hand for the detection of small pencils and fragments. Mr. Tannenbaum's agent at the Himalaya mine is J. Goodman Braye, Jr., an African by descent, an Australian by birth, and an American by choice. His successful career as manager of the greatest tourmaline mine in the world (and possibly the greatest gem mine in America), is sufficient proof (if any proof were needed) that the accident of race and color constitutes no insuparable barrier to achievement.

On the claim adjoining that on which the Himalaya mine is situated is the mine of the San Diego Tourmaline Mining Co., which has been operated ever since 1901, and has yielded a large quantity of beautiful gem material. Here the vein material is a fine-grained pegmatite, in which black tourmalines occur in fan-shaped crystallizations. Near the centre are found pockets, in which are the crystals of gem quality. This mine also ranks well up among the great gem mines of California.

It is only within comparatively recent years that tourmaline has been used to any considerable extent in jewelry in this country. In fact, until after the opening of the Mesa Grande mines there was little tourmaline of gem quality on the market. All of the output of the Himalaya mine is shipped to New York to be cut, but that of the San Diego mine is cut in San Diego, where a number of skilled lapidaries are constantly employed. There can be but little doubt that as this beautiful gem material becomes better known it will gradually grow in popular favor until it takes first rank among American gem stones. The hardness of tourmaline is variable, usually being 7 or 7.5 in the scale in which the hardness of the diamond is 10. However, it is said that specimens at Mesa Grande are often found with a hardness of 8. Tourmaline is defined as 'A complex silicate of alumina, boron, magnesia, iron, and alkalies (soda, potash, lithia), with small amounts of water and fluorine'. Different names are given it according to its color.

Present Conditions at Ely

STAFF CORRESPONDENCE

The principal operations of the Nevada Consolidated Copper Co. are at Copper Flat, seven miles from Ely, Nevada, where five Bucyrus steam-shovels, with 3½ and 5-cu. yd. dippers, are loading into cars 240,000 tons per month of mill ore, and in like manner disposing of a great tonnage of overburden. In performing this work eight 45-ton locomotives, and one of 60 tons, are in use. The main pit, which is the centre of operations, is nearly 2000 ft. long, 1000 ft. wide at the top, and 180 ft. deep from the highest rim to lowest part of the excavation. The shovels are operating on four terraces. The long diameter of the pit lies north and south, the trackage for the ore trains entering from the north; the pit has drainage in the same direction into an arroya. The work at the head-end of the pit is extending toward a limestone hill, and will be continued south to the contact of porphyry with this limestone. The greatest progress of the shovels, however, is westerly, or in a lateral direction. The overburden, the greater part of which is taken to the waste dump, is 85 ft. thick. The rock in certain shoots of this porphyry capping, containing 75 to 80% silica, and 2 to 4% copper, is sent to the smelting plant and used for converter lining. The defined ore stratum, below the overburden, carries 80% silica, 3.5 iron, 2.1 copper, and 0.5 lime. The copper is disseminated through the gangue as chalcocite, and is considered a secondary enrichment of the monzonite-porphyry. The ore is 200 to 300 ft. deep, as was demonstrated by churn-drill work in the vicinity of the main pit. The body of ore against which steam-shovels are now working is about 60 ft. deep, although the pit is being made deeper. A second pit is being opened a short distance west from the one above described, where two new steam-shovels will be put in operation, the result of which will be to increase the tonnage of ore that can be shipped to the concentrating plant at McGill.

Steptoe Concentrating Plant, Ely District.

The milling and smelting plants are operated by the Steptoe Valley S. & M. Co., a subsidiary of the Nevada Con. The Nevada Northern Railroad Co., whose main line extends from Cobre to Ely, with one branch from Ely to the mines of the district, and another to the mill and smelter, is another subsidiary. The concentrating mill is built in eight sections, two sections making a unit, with a rated capacity of 750 tons daily per section; but this capacity has been greatly exceeded. It is stated that as high as 10,500 tons have been put through in 24 hours. With only seven sections now in operation the plant already handles between 8000 and 9000 tons per day. The ore is first passed through McCulley gyratory crushers. There are 8 sets of 15 by 36-in. coarse rolls, and 16 sets of 14 by 36-in. fine rolls, Allis-Chalmers type. In each section are 68 Wilfley tables and 48 A.-C. vanners; four elevators, 12-ply, 20-in.; four 6-ft. Huntington mills and one Garfield Chilean mill; eight Steptoe classifiers; eight 2-mm. revolving screens and two ½-mm. screens for dewatering; and 46 Callow tanks. The Steptoe classifier is a modification of the one devised by Pope Yeatman, as shown in Richard's 'Ore Dressing'. The modification, which effects radical changes, was made by Geo. F. Waddell, mill superintendent, and his staff. These classifiers receive the re-ground material from the Huntington and Chilean mills, and the middling from the first-floor tables, also the undersize of the 2-mm. trommels. They effect classifications for different sets of tables and vanners, each set receiving its classified product through a particular spigot. The result is said to be greater efficiency and speed in this branch of the work. Another change in the practice here consists in taking out No. 1 trommel, which was formerly used to take up an undersize before wet-crushing in coarse rolls. This trommel having been taken out, the entire feed of the mill passes direct to the coarse rolls, which operate dry instead of wet as formerly. This change has served to increase the capacity, makes a steady feed possible, with no choking of rolls. The change from wet to dry crushing, as applied to the coarse rolls only, and the installation of the Steptoe classifiers, are said to have resulted in adding 60% to the capacity of the mill. The process becomes a wet one after the pulp passes through the coarse rolls, of which there is one set to each section. With the proposed increase in mill capacity, that is expected to come with the increased ore supply from the mines, it is thought that ore may be put through the mill at the rate of one ton per minute per section. A tonnage recorder, which works as a meter, and devised by Fred Curtis, the chief sampler, indicates to the superintendent, or foreman, just what tonnage is passing through each section each hour. The mill concentrates approximately ten tons into one.

The concentrate is delivered to the 16 McDougall roasters in Atlas hopper-bottomed steel cars, each of 10 tons capacity, the cars of concentrate being weighed on track scales. The roasters are of the Anaconda type, set in two parallel rows, the calcined product discharging into calcine hoppers, and from these it is taken hot to the reverberatory furnaces in closed cars. There are five reverberatories,

each 19 by 110 ft., the waste heat from which is passed into eight Sterling and two Babcock & Wilcox boilers, the steam from which is utilized in the power-house and in heating the concentrator building during the winter season. The reverberatory slag is skimmed off and granulated in waste water from the mill and discharged through a launder on the flat below the plant. The matte is taken to the converter building in steel matte-pots, and poured into the converters through cast-iron runners. There are four stands of converters, with three shells to each stand. The converter slag, after being skimmed off into truck-pots, is taken hot to the reverberatories for re-smelting. It is tapped out of the pots through a cast-iron spout into the furnaces. The converter lining, consisting of silicious copper ear-

bonate ore, is dried therein by the ashes from the reverberatory furnaces, consisting of partly consumed coke and coal. C. B. Lakenan, general manager for the company, states that in April the concentrators made a saving of 71.84% of the copper content, and that the smelting process resulted in an extraction of 95% of the copper in the concentrate. This ore carries 40c. per ton in gold and 2.1% copper.

A new Nordberg horizontal cross-compound blowing engine, to supply the blast for the converters, was installed in the power-house in February, and at the time of my visit it was undergoing acceptance tests. The steam cylinders are 26 by 56 by 48 in.; the air cylinders, 54 by 54 by 48 in., the low-pressure cylinders being steam-jacketed. The receiver is of the re-heating type. The engine is rated at 18,000 cu. ft. of free air per minute; speed, 75 r. p. m.; guaranteed duty, 1.28 lb. steam per 100 cu. ft. of free air compressed to 17 lb. The fly-wheel is 20 ft. diam., weight 52,000 lb. The steam is supplied at 150 lb., and superheated 100° to a temperature of 465°F. The engine is equipped with a Wheeler condenser and Wheeler-Edwards air-pump; an oil-filter system, whereby the bearings are kept flooded with oil. The old blowing engines heretofore in use will be kept in reserve. A system of air-coolers for the roasters, to replace the water coolers, is being installed. It consists partly of fans operated by electric motors.

The reverberatory ash, containing 70% fixed carbon, 20 ash, 5 volatile matter, and 5% H_2O, is used as fuel under the boilers in the power-house. The converter building is being extended to afford more room, and an additional reverberatory furnace is being built. In obtaining data herein, I am under obligations to C. B. Lakenan, general manager; S. S. Sorrenson, chief engineer; R. E. H. Pomeroy, assistant superintendent of smelter; Lindsay Duncan, mechanical engineer; George F. Waddell, mill superintendent; F. W. Solomon, mill foreman; and Fred Curtis, sampler.

The Boston-Ely Mining Co., the principal stockholders in which are residents of Boston, has 20 patented claims a short distance northwest from the Veteran holdings of the Nevada Con. The shafts of the two are about 1700 ft. apart. E. W. Ralph, manager for the Boston-Ely, states that, in sinking their shaft to a depth of 1160 ft., the first 865 ft. was in unaltered limestone, below which was intrusive material. Some leached material was found at the end of a cross-cut driven 215 ft. from the shaft at the depth of 710 ft. The contact of limestone and jasperoid was cut at 800-ft. depth by driving a 95-ft. cross-cut. This contact, which has a dip 53°, was cut by the shaft at 865 ft., and at this place copper carbonate was found. At 1127½ ft. a cross-cut was driven north to the contact, where a winze was sunk 150 ft., following the dip of the contact, obtaining sulphide material, running 25 to 30% iron, 50 to 60 silica, 10 sulphur, and 12 to 15 lime. The intention is to continue sinking on the contact. The hoisting has been done with gasoline power thus far, but this probably will be supplanted by a steam plant.

The Ely Central Copper Co. is sinking and developing at its Eureka and Clipper shafts. The former is situated 400 ft. east of the main pit of the Nevada Con.; the latter is 4000 ft. to the west, in limestone. The Eureka shaft is believed to be on the same east-west ore-zone as that of the Nevada Consolidated's Copper Flat pit, but the most of its Eureka group lies east of the fault plain, where the orebody, if found, will be at much greater depth. The shaft is now down 475 ft. At 462 ft. a streak of carbonate ore was obtained, some of which assayed 15.5% copper; this was on the fault-plain contact. At 465 ft. some iron-copper sulphide was found. A cross-cut was driven east at the 470-ft. station to the contact and an incline is being sunk thereon. Some driving is also being done north and south on the plane of contact. The character of the ore obtained in small stringers seems encouraging. The Clipper shaft has been sunk 205 ft. on what appears to be a fissure in the limestone, having a north-south strike, a dip of 60° west, of undetermined width. The gangue is lime and jasperoid, carrying iron and copper, consisting of carbonates in the cropping. The 3-compartment shaft cuts through the vein on the dip of the latter between the surface and the 180-ft. point. Sinking will be continued to a depth of 300 ft., and from this station a cross-cut is to be driven to the vein, which will be explored at that depth, in the hope of finding there a more concentrated orebody. There is a considerable flow of water here, requiring the good pumping facilities which have been installed. The plant contains three steam boilers and a small capacity hoist. The management of the Ely Central is now in the able hands of Lee Glockner.

N. A. McGill has leased the Southern Cross claim of the Chainman group, also the dumps of the entire group, and the Chainman mill. He is putting the mill in order for crushing, amalgamating, and cyaniding, and intends treating some of the dump material as well as ore from the mine. A 72-ft. raise has been made from the 400-ft. adit, and a drift has been run 200 ft. from the top of the raise to tap the orebody from which mill-ore is to be taken. Sam Coeroft has charge of the mill.

WORLD'S OIL OUTPUT

The world's oil industry is a constantly growing one, with the United States the largest producer, with an annual output more than double its closest competitor, Russia. The 1909 production is estimated at 281,000,000 bbl., compared with 278,000,000 the preceding year, and 262,000,000 in 1907. The output of this country last year fell off 10,000,000 to 170,000,000 bbl., but all of the other principal producers showed substantial gains. The world's production for three years is given below:

	1909. bbl.	1908. bbl.	1907. bbl.
United States	170,000,000	180,000,000	166,000,000
Russia	55,000,000	52,500,000	62,000,000
Galicia	15,000,000	11,000,000	8,000,000
Rumania	9,000,000	8,000,000	8,000,000
Dutch East Indies	21,000,000	16,000,000	10,000,000
India	5,000,000	4,500,000	4,000,000
Mexico	3,000,000	4,000,000	2,000,000
Miscellaneous	3,000,000	2,000,000	2,000,000
Total	281,000,000	278,000,000	262,000,000

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Graphite in Cyaniding

The Editor:

Sir—When I wrote the article 'Graphite—an Obstacle to Good Cyaniding', published in your issue of December 4, 1909, I was simply giving my experience with it, and the trouble that it gave in other mills here, not dealing with graphite ore in other parts of the world; and I still maintain that, "the trouble here can only be minimized by carefully excluding such ore from being sent to the mills," in spite of D. F. Foster's good results at Ashanti, as in his letter of your issue of February 5, 1910. I take it that, at Ashanti, the graphite is always present, whereas in Kalgoorlie, it only comes in occasionally, sometimes being easily detected, and often being so finely distributed that it is not noticed until it floats on the pans. Mr. Foster does not give the percentage of graphite in the Ashanti ore, but we have some that runs much higher than the 0.75% average in the analysis in my notes. Up to a certain point, the treatment of the two ores mentioned is similar, beyond that it differs greatly. At Kalgoorlie all the roasted ore must be slimed for subsequent agitation with 0.08% KCN. Damping down the roasted product with water or KCN was tried here 11 years ago with disastrous results, as the lime and magnesia present in large amounts in the average ores milled were converted into sulphates during roasting, and on this being wetted, the ore set like cement in the percolation tank, the consumption of KCN being high and extraction as low as 65%. This will show that the Ashanti ore is much easier to deal with than the ore here. Regarding the roasting of an ore containing graphite, it seems to me to be excellent work to burn out this mineral by manipulating the air-inlets near the firebox, but this has been unsuccessful here so far, although all these things have been tried with the Merton, ordinary and improved, and the Edwards duplex type of furnaces. Roasting has reached a high state of efficiency at Kalgoorlie. The roast is tested for sulphur as sulphide by the iodine method, no special test being applied for graphite, as it is not always known when it is coming in. What happens at Ashanti when there is a poor roast, which happens in the best regulated furnaces at times? Is the extraction low? With regard to residue containing graphite and fair values in gold, I may say that many thousand tons of this have been successfully treated here, proving that exposure to the atmosphere changes the condition of the residue somewhat. As to extraction, in 1909 the average was 93%, often being as high as 95%, but the graphite at times lowered it to 90 per cent.

Only one mill here that employs the wet crushing, all-sliming treatment is bothered with graphite, the mine being on the eastern side of the belt where most of this mineral is encountered. Its effect in the cyanide treatment seems to be much worse than in the roasting plants. Graphite is a very stable mineral, and no doubt a little is burnt in the furnace, but so far roasting has failed to eliminate all of it, and as I said before, it only comes in occasionally, being one of those little troubles that is a nuisance for a day or two and then disappears for weeks. The Associated Northern Blocks and Oroya-Brownhill group of mines, where much graphite has been met with, are almost worked out. The Associated gets a little, and the Great Boulder also where a good deal has been encountered of late in the lower levels, 2500 feet.

It is rather an interesting subject, and at Ashanti the problem appears to have been solved by quite a simple method; and yet here we cannot get the usual high extractions when graphite is present. In the published returns from the Ashanti company, I had noticed that roasting was part of the treatment, and wondered what the ore was like. Through the medium of correspondence in your journal, I have been enlightened on this and other points.

M. W. VON BERNEWITZ.

Kalgoorlie, Western Australia, March 4.

Federal Authority and Conservation

The Editor:

Sir—The suggestion has been made repeatedly that the simplest solution of the difficulties incident to the conservation policy would be to transfer the whole of the public lands to the States within which they lie. Many ardent conservationists favor this policy. Since the mining industry in the West is so intimately connected with the public lands, I would be glad of space for the consideration of this proposal.

In the first place it should be noted that in the treatment of problems of this sort the States, as the possessors of the so-called 'municipal authority', have much more power to deal adequately with them than can the United States. The authority of the latter rests on its ownership of the land, and, except in the circumstance that Federal lands are not subject to condemnation under State laws, it has no more authority in the matter than John Jones or Richard Roe would have as owner. The ownership of the land carries no right of sovereignty different from that which the Federal Government has over all land. There is no contention, I believe, that the United States Government has the right to pass regulative laws covering land in private ownership such as have been proposed for the public lands. Its authority in the matter of regulating water-power, for example, probably must rest exclusively on its ownership of lands necessary to the building of dams and erection of power stations. In States where riparian rights are recognized it would have these, as would any other owner. Where only the law of appropriation is recognized, it would have the same right, though there is a question as to the policy of utilizing it, to make appropriations of water to benefit its lands, as would a private citizen. In addition, it would be proof against condemnation suits. The power of Congress "to dispose of and make all needful rules and regulations respecting

the territory or other property belonging to the United States" is expressly granted in the Constitution, and under the ruling laid down by Judge Marshall to the effect that a power actually delegated to the United States should be interpreted liberally, the legal authority of the Federal Government to introduce a leasing or any other system of regulation of the public lands seems clear. Remembering that the public domain still includes a large portion at least of the forest, coal, oil, and phosphate lands, and of the important power-sites, it is evident that while the authority of the United States in the matter is only that delegated by the Constitution, it is still broad enough to form a basis for effective regulation. At the same time the authority is subject to strictly defined limits and it would be impossible, except by alteration of the Constitution, to extend it.

On the other hand there are practically no limits to what the State may do, except as set by each State constitution, and while these vary greatly the powers of all are broad. There is little question not only that the States may pass effective legislation, but it is conceivable that they might even enact oppressive laws. The railways profess to have already found State regulation even confiscatory. If the public lands were transferred to the States the power of the latter would be subject to very little limit. The present division of authority in the matter, by bringing into action not only local but general public opinion, is likely, as it seems to me, to produce better results than would a complete grant to either the State or Nation. Certainly it accords with the general theory and practice of our Government.

In the above I have taken no account of the arguments for and against the proposed transfer, that are based on policy. They are too numerous, and differences of opinion are too radical to permit summary here. The suggestions I have given are also, it may be confessed, those of a layman as regards the law. If they are not sound will you or some of your readers kindly set me right?

CONSERVATIONIST.

San Francisco, May 27.

Columbia University has received an anonymous gift of $350,000 for a building for the faculty of philosophy. A gift of $150,000 for the erection of an administration building and library at the Rensselaer Polytechnic Institute has been made by the Pittsburg Alumni Association. The medical school of the University of Pennsylvania has been given $100,000 by an unnamed alumnus to endow a chair to be known as 'the Benjamin Rush professorship of physiological chemistry'. Tufts College has been made the residuary legatee under the will of John Everett Smith, and will, it is said, receive on the death of Mrs. Smith, the sum of $500,000.

The prohibition against the use of telegraphic codes in Turkey has been removed and all code messages, except those in cipher, will in future be received for transmission at all telegraphic offices of the Ottoman Empire.

MINING INDUSTRY OF PORTUGAL

According to Louis H. Aymé, Consul-General at Lisbon, the mineral output of Portugal in 1908 amounted to $1,786,626.

Of the ten minerals mined, copper is the most productive—97,477 metric tons of concentrate, with a value of $632,254. Sulphur follows, with 24,522 metric tons, of the value of $596,478. Tungsten comes third, with 620 tons, of the value of $240,052.

Further details are given in the following table, which shows the percentages, weights, and valuation of the ten most important minerals:

Minerals.	Metric tons.	Value.
Antimony	76	$2,826
Arsenic	1,655	90,360
Auriferous silver	2,244	58,770
Coal	4,614	19,912
Copper	15,313	58,001
Copper matte	564	56,529
Copper precipitate	3,041	386,150
Copper and iron pyrite	81,417	128,551
Copper and lead	142	3,123
Gold	1,832*	36,990
Lead	481	9,225
Sulphur	24,522	596,479
Tin	28	9,153
Tungsten	620	240,053
All other	.....	90,504
Total value	.....	$1,696,122

*Troy ounces.

There were employed 7160 persons in mining—6426 men, of whom 2889 worked below ground and 3537 above ground, and 734 women, who all worked above ground. The fatal accidents during the year were 9, or 1.25 per thousand.

FOREIGN COPPER STOCKS

The British Board of Trade figures of copper holdings (in tons) are given below:

	1910.	1909.
STOCKS JANUARY 1		
London, Liverpool, and Swansea	95,670	40,960
Imports January 1 to April 30	53,036	47,538
	148,706	88,498
Exports same period	24,025	24,811
	124,681	63,687
STOCKS APRIL 30		
London, Liverpool, and Swansea	95,690	37,970
Apparent deliveries 4 months	28,991	25,717

The Associated Transportation Co. owns four modern tank steamers, has one on the way from Newport News to the coast, and has since placed orders for another; owns four large schooners, three barges, and three tugs. These, including the pipe-lines, are in the exclusive service of the Associated Oil Co. Of the $5,000,000 of the Amalgamated Oil Co. the Associated owns $2,500,500. This company owns and leases oil lands in Los Angeles county, and owns a pipe-line of 15,000 bbl. daily capacity into Los Angeles, where it has terminal facilities and a refinery with a daily capacity of 3000 bbl. The above pipe-lines give the Associated Oil Co. a daily capacity of 78,000 barrels.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The quantity of lime produced in Canada in 1908 was 3,601,468 bushels valued at $712,947, or an average of 20c. per bushel; as compared 4,755,316 bushels valued at $974,595, also an average of 20c. per bushel in 1907.

Silver is found in the Central States in small quantity. In 1908, 292,237 oz. were recovered in treating the copper ores of Michigan, the lead ores of southeastern Missouri, and the zinc-lead-fluorspar ores of southern Illinois and Missouri. In the latter district the silver content is about enough to pay freight on the lead concentrate which is, itself, a by-product from the milling of fluorspar ore.

Petroleum reserves are hard to estimate. For California Ralph Arnold has calculated that 8,500,000,000 bbl. exist stored in the rocks, and that of this amount 5,000,000,000 may be expected to be produced. D. T. Day estimated for the National Conservation Commission, the total maximum and minimum possible yields in the United States at 10,000,000,000 and 24,500,000,000 bbl. respectively.

Zirconium, while now known to be more widely distributed than was formerly supposed, is still much less common than titanium, rarely making up 0.2% of a rock and being usually under 0.05%. It is most apt to occur in granites, rhyolites, syenites, nephelite syenites, phonolites, tinguaites, and tephrites, and is most abundant in those which are high in soda, such as the last four. Its most common form is the silicate zircon.

Phosphate rock occurs principally in South Carolina, Florida, Tennessee, Utah, Idaho, and Wyoming. In 1909, F. B. Van Horn, of the United States Geological Survey, estimated the available tonnages as follows: South Carolina, 3,000,000; Florida, 15,000,000; Tennessee, 103,500,000; Western States, 100,000,000. Surveys are too incomplete as yet to permit of more than the above approximations.

The oil shale deposits of New Brunswick, which cover large areas in Kings, Albert, and Westmorland counties, have been known for a long period. As early as 1862, some steps were taken toward their exploitation as a source of mineral oil. This enterprise, however, was soon abandoned after the discovery of the Pennsylvania and other oilfields, and it has been only within recent years that any work has been done in an attempt to develop the field.

Arsenic in Canada, up to 1903, was mainly produced at the Deloro mine, in Hastings county, Ontario. The arsenic was recovered at Deloro in the process of treating the auriferous mispickel ores found in the district. In 1902, however, the mine was closed although the mill continued to work on tailing and ore from the dump until 1903, when operations ceased altogether. This property has been recently taken over by the Deloro Mining & Reduction Co., and the entire plant re-built with the object of treating ores from the Cobalt district as well as the local mispickel ores. The ore shipped from the Cobalt district contains important quantities of arsenic, although practically nothing is now paid to the mine owners for this mineral. There are three plants in operation in Canada producing white arsenic; one at Copper Cliff, operated by the Canadian Copper Co., a second at Thorold, operated by the Coniagas Reduction Co., and the third at Deloro.

Sampling churn-drillings by splitting of a stream of sludge is easy but it is also easy for a careless sampler to neglect his work, especially at night. An unwashed trough may collect much concentrate; an uncleaned divider may clog and not split the sludge properly. Allowing the solids in a sampler to settle and decanting off most of the water before placing the tub over a fire, is a common and legitimate practice—but too often much solid matter is allowed to float out with the water. However, regarded not as a means of developing orebodies, but as a means of prospecting for them, determining their boundaries and obtaining a fairly close idea as to their tenor, the churn-drilling machine is certainly a rapid, efficient, and comparatively cheap instrument.

Raw silver ores amenable to the patio process of treatment are also usually amenable to cyanidation. An exception to this rule is where the ores contain 0.2%, or so, of copper in the form of oxide or carbonate, in which case, though they may be ideal for the patio process, the copper causes such a consumption of cyanide as to make the cost of cyanidation prohibitive. Fortunately this condition of affairs generally occurs only near the surface. In many old mines where the patio process was used the lower-grade surface ores were left, ostensibly because of being too low grade to treat. It quite often happens, however, that the real reason was because these surface ores were refractory to the process, containing the silver in combination with manganese. Such ores are found to be equally refractory to the cyanide process. The cyanide process has displaced the patio process, not because it gives a better percentage of extraction, but because it is a cheaper and quicker process.

'Caterpillar' or 'paddlewheel' traction engines are being used with great success to haul heavy machinery over the sandy roads in the construction of the Los Angeles aqueduct. This type of engine, instead of having the large hind wheel commonly known, carries its weight on five truck wheels which run on a track of plow steel, so protected that it is nearly impossible for sand to reach the bearings. The hind wheels are of the sprocket type, and engage an endless belt of 'shoes' or 'platforms' which pass around the sprocket and centre wheels, 18 inches distant, the latter acting as idlers. These platform wheels have the same tractive area as an ordinary round wheel 54 ft. in diameter. Power is furnished by a 40-hp. gasoline motor using distillate at a cost of less than 1c. per horse-power hour. Loads vary from 15 to 20 tons on level roads and the cost amounts to 20c. per ton-mile for the engines against 40 to 50c. for teams.

JOPLIN, MISSOURI

Deep Runs as Oronogo.—Granby Changes Plans.—New Mills. — Spring City Mines.—Galena Ground Drained.

The most important move of the last fortnight probably was the opening of the deep levels in the Oronogo Circle mines at Oronogo. The deepest ore-level in the entire district has here been made available for working. The company began deep mining several years ago opening a 230-ft. level which was then considered deep. Later the Herald and Empire mines at Galena surpassed this by operating down to 290 ft. The Oronogo company has been drilling for several months, the drill-rig being operated from the 230-ft. drifts. The results have been highly gratifying, as ore was found almost continuously down to 385 ft., the entire thickness being workable and of high grade; in fact richer than that hitherto worked at shallower levels. Two distinct runs were penetrated, part assaying over 12% zinc, and the entire face averaging 4 to 5%. This company is starting mill No. 7, which will now make four large plants operated and give a weekly 'turn-in' of 300 tons of blende and 40 to 50 tons of galena. Another move of importance is the plan of the Granby M. & S. Co., the largest single land-owning and operating company in the district, to develop and prospect its own lands instead of following the previous policy of sub-leasing and allowing the sub-lessee to do the prospecting. The company has been draining a large area in the eastern part of the Oronogo camp, and was successful until the water was lowered to 125 ft., when several large and disastrous caves occurred and caused the work to stop indefinitely. Many small buildings were destroyed and the pumping plant was damaged. This ground was formerly extensively mined for shallow ore and the entire tract is cut up by drifts and gouges. Deep mining is to follow the draining, as the company has discovered ore at similar depths and in similar formation to that mined in the Oronogo Circle. The Granby company has also started prospecting on its land at Chitwood, where a number of holes have been sunk, and others will be put down. The land is surrounded by good producers, although little work has been done on the tract itself. The mineral occurs in open ground from 154 to 180 ft. One of the largest recent deals in the district was the consolidation of the Yale and Providence mines at Webb City whereby the Yale will be known as the Providence No. 2, and both will be operated by the same company. The Yale is southeast of the city and has a large mill on a 30-acre lease where ore is taken from two shafts at 192 and 172 ft. in depth. Many improvements are to be made in the equipment and the capacity increased. A face of ore assaying 3% and running from 12 to 18 ft. high is worked. The Providence is a large property in the north Webb City sheet-ground field and is one of the pioneers there, having a highly successful history. Prospect work continues unabated throughout the fields and many important strikes have been made recently. In the vicinity of Toms Station north of Joplin recent discoveries of importance have been made. In Leadville Hollow zinc blende of high grade has been found. Matthes Bros., southwest of Joplin, owning over 2000 acres, have begun to open two additional shafts and will operate the 500-ton mill at full capacity. The Chitwood-Dale company has taken a lease at Prosperity. On an adjoining lease the McKinley mine which has long been idle is being re-opened. The old Monday mine in the Alba camp is being re-opened by Green, Coffe & Windland. Among the new mills is the Bird Dog No. 3 at Webb City, which has made the trial run with success. It is located on a sub-lease of the rich Kansas City-Bradford mine and is one of the large mills of the camp, having a capacity of 350 tons. Gates, Madera & Sawyer have completed their mill in the south Webb City field and will be ready for operation at once. The Ave Maria mill south of Webb City has been taken over by the Nowata company, who will make a test run in order to decide if the property will longer be worked.

At Spring City, in Newton county, the introduction of gas as fuel has livened matters materially. The old Delta mine, now operated by Creech & Co., is proving wonderfully rich. A rich stope beneath the old drifts will be taken up. The lateral extent of the orebody has not been learned. Complete recovery is impossible, as hand-jigs are used. The 'crush rock' will be re-worked when the mill is built. A mill is being built on a lease recently acquired from Arthur Scott. A shaft is in ore and driving has been started at a depth of 115 ft. Sludge tables and every modern appliance will be installed. Louis Anthony, of Texas, has bought a sub-lease of Adam Scott on the Bittick land and will complete prospecting before further development. Three holes have already been sunk showing ore at 135 ft. in a disseminated formation, whereas most of the ore in this camp is of the blanket variety. A shaft will be started on one of the good holes. Calamine and lead ores at a shallow level are being widely prospected. A company has taken a lease on a portion of the Adam Scott land and is working two shafts, one 40 ft. deep, the other 50 ft. Both will be sunk to 60 ft. where good calamine is found. Hand-jigs will be used for some time, though the company is planning a mill later. The Microbe company is to re-open the 100-ton mill on the lease of the St. Paul land. A new shaft is being sunk on a drill-hole. Excellent ore has been discovered at 150 ft. in several holes, the formation being similar to that worked in the old Delta mine. A new mill is to be erected on the Rose land just south of Joplin, where three hand-jigs have been busy for a long time, averaging 5 to 6 tons of ore per day. Some of the lead occurred in huge chunks. Operations are being carried on at 165 ft., where four drifts are driven into good ore. If the lower ground proves satisfactory a steam-mill will be built.

Prospecting in the Joplin District.

The draining of the Luscombe and Sapp forties southwest of Galena has been completed and 80 acres of valuable mineral land are thus added to the Kansas field. The operating company will reserve two ten-acre tracts, subleasing the remainder to the 110-ft. level, and reserving the right to prospect and mine the entire land beneath this depth. A mill has been bought at Miami and is being re-erected. Enough ore is in sight to last for several years. The draining of these tracts, together with the unwatering of the Boston, Foster, and Playter lands, makes a large additional acreage available for mining purposes. A large

mill has been started at Cave Springs where a deposit is being worked at 110 ft., unlike that of the Herald nearby, where the ore is found at more than 200 ft. in depth. Both zinc and lead are found in the new mine. A number of drill-holes have been sunk, finding ore at various depths, including deep deposits as well as shallow. Another mine in this camp, operated by Buxton, Sloan, and others, is being worked by hand-jigs and good 'turn-ins' are being made on ore taken from below the 75-ft. level. Below the 100-ft. level a stope will be taken up. A deeper run will be worked later. Much of the ore had to be piled up, as it could not be worked profitably on hand-jigs. Two shallow strikes have recently been made near Baxter Springs, which is unusnal there. Newton Cox & Co. have taken the right to mine the shallow pockets on the Baxter Royalty land and are using hand-jigs to clean the ore found in a chimney 100 ft. diam. and extending to the usual 50 to 70 ft. depth. The ore is of the pebble variety, particles varying in size up to that of a walnut. A second-hand jig plant is being operated by Rhodes & Sullivan on the Catholic forty, where ore is found in open ground at a depth of 20 feet.

AUSTIN, TEXAS

Development Hampered by State Laws.—Mineral Surveys.

The exploitation of the Toyah oilfield in western Texas has developed an interesting situation with regard to the legal rights of the State in the matter of holding public land which is believed to be oil bearing. It is claimed by the men who are seeking to acquire mineral rights to certain lands in that district that J. T. Robison, the State Land Commissioner, has arbitrarily refused their applications to prospect for oil and other minerals upon the land in question on the ground that "there is no evidence in the land office that the land is apparently mineral bearing." It is contended by the men who want to prospect these tracts that the mining law does not provide that such land must be officially classified as mineral bearing before it is subject to entry for prospecting purposes, and that the Commissioner is exceeding his authority. The law provides that land containing the minerals such as kaolin, baryta, salt, marble, fire clay, iron ore, coal, oil, natural gas, gypsum, nitrates, mineral paints, asbestos, natural cement, clay, onyx, etc., shall be sold for not less than $15 per acre when situated ten miles or less from a railroad, and not less than $10 per acre when the land is more than ten miles from a railroad. One-tenth of the money shall be paid to the State Treasurer on or before 12 months from the date of purchase. The remainder of the purchase money shall be paid in nine annual equal installments with interest at 4%. The law gives the applicant to purchase land that is believed to contain oil and other base minerals 12 months in which to prospect before making any payment, during which period it cannot be sold to other purchasers. It is this provision that is evidently defective, for the reason that under it a corporation could sink wells on the land and largely exhaust the oil supply before being called on to make the first payment. It could then abandon the ground without having paid the State anything for the land or the oil.

During the period that the State had a department known as the Mineral Survey a considerable part of the mineral region of western and southwestern Texas was mapped and classified under the direction of William B. Phillips. The legislature failed to make appropriation for carrying on the important work of this department and it passed out of existence. There is still a big territory which is believed to be mineral bearing that has never been classified. Under the ruling of Mr. Robison no prospecting can be conducted upon this land, simply because it has not been classified as mineral. Considerable attention is now being given to the mining of silver, copper, and zinc ores in the upper Rio Grande border territory, but these operations are all confined to private lands. The tin deposits near El Paso are also attracting attention. It is stated that another effort will be made at the coming session of the legislature to enact a new mining law that will encourage the development of the State's vast mineral resources.

JARBIDGE, NEVADA

Work Being Resumed. — Pick & Shovel. — Pavlak.—Buster. — North Star.—Jarbidge-Vulcan.—Bonanza Gulch.

Not much change in the Bourne or North Star company property has occurred, and the inactivity at this mine and consequent lack of results has had a depressing effect on the general public as far as Jarbidge properties or stocks are concerned. It has been extremely difficult to finance any property and consequently for a time there was little or no work done. Finally the Pick & Shovel Co. management changed and a little work was started under the charge of W. W. Scott, of Eureka, Utah. This has resulted in finding good ore and has encouraged the company to increase the working force and begin at other points. The Pavlak company, under the management of Sidney Coburn, has been carrying on a system of development which promises to place the Pavlak property first in line as a mine. A cross-cut is being driven from the mine east into the mountain to cut the Pavlak lode below the shaft. This is expected to cut the vein at a depth of over 300 ft. in a distance of 400. The cross-cut is now in 100 ft. and is within a few feet of another mine known as the Taft lode. Numerous stringers of quartz, talc, and iron have been cut, which are supposed to be feeders of the Taft vein, and as these stringers assay from a few dollars to nearly one hundred per ton, it encourages the management to believe that the Taft vein may have real value. The same company has four sets of lessees at work along the main vein, two south of the shaft and two north of it. The two south of the shaft have found good milling ore, but no high grade, and have consolidated their interests. Mr. Boylan has gone out to finance a small leasing company to properly develop the ground and put a small mill up to treat the ore. The lessees north of the shaft have been more fortunate and have some high-grade ore; in fact, the block north of the shaft promises to make the first shipment of high grade from the camp. Here they have stripped the vein the full 300 ft. across their lease and for 200 ft. have a narrow streak of high-grade ore from one to three inches wide along one wall that pans well. A series of twelve samples from this streak gave assay returns of $316 and $844 per ton.

Just north of the Pavlak ground and between it and the Bourne is the Buster group of claims which has been taken up by the same brokers who financed the Pavlak company. This property has a fine showing with a dike outcropping for 600 ft. in length up the hill-side. This company will also start a cross-cut from near the river and run about 150 ft. to the vein, then turn and run with the vein. The quartz on the surface is from a few feet to 30 ft. wide and shows small amounts of gold both in the pan and by assay. On the North Star property one of the lessees has resumed work and has six feet of vein matter which assays from $8 to $20. Clark and Fletcher have secured a lease on 600 by 600 ft. on North Star No. 3 claim, beginning 20 ft. from the face of the Bourne adit. This is a promising piece of ground, and the men are mining men who have both money and backing. The Jarbidge-Vulcan Mining Co. has secured the services of G. L. Snyder, of Denver, and proposes to develop its ground, lying up the mountain some distance east of the Pavlak and Buster. The vein where exposed on the surface carries small amounts of gold and there is rich float below it, which is believed to have come from some part of the vein now covered with slide rock. Large quantities of rich float are found on the ridge south of Bonanza Gulch. This ground lies south of the Pan and west of the Shovel claim. Several owners of claims along the ridge are trying to find the vein or veins from which this float comes. Some think it all comes from the Pick & Shovel lode, but there seems to be too much of it and it does not appear to be the same as any yet found on the Pick & Shovel. A Tacoma, Washington, company has bought a group of claims on the west side of the river and west of the lower end of town, about halfway between the river and Deer creek. These were known as the Blake group and were bought for cash. A 1000-ft. cross-cut connecting with a 250-ft. shaft is to be driven. Several large lodes which

pan well at the surface are present. Theodore Parks has moved his whole outfit up the river four miles to begin work on the Good Luck group. The Twin Falls Free Gold Mining & Milling Co. has just sent in an outfit to begin work on the Free Gold group of ten claims five miles up the river. There is a belt crossing this property which is in places 100 ft. wide and gold can be found by panning all along. The vein is the same that crosses the Jarbidge Wonder property. Just above the Free Gold on a parallel vein higher up the mountain and to the east, the Big Four company is preparing to start work. About two miles farther up the river near what is called 'the Forks' some rich float has been found and one vein opened that yields assays of $30 to $40 per ton.

MEXICO

Nueva Luz, Guanajuato. — Amparo, Jalisco. — Seguranza y Anexas. — Power Plant for Northeastern Sonora. — Yaqui River Smelting.—Zinc Mine at Cananea.— Fomento Laboratory.

A large shipment of new machinery recently ordered by Carl Henrich, manager of the Nueva Luz mine at Guanajuato, is on the way. This includes pumps adequate to handle 400 gal. per minute in three stages, from a depth of 2000 ft. There are three triplex pumps of 100 and 300 gal. respectively, driven by two-speed motors of 30 and 100 hp. Over 2400 ft. of transmission wire has been ordered from Siemens-Schuckertwerke to transmit power to the pumps. This company is now receiving financial assistance from the Government on the subvention granted for sinking the shaft. The work was recently inspected on behalf of the Government by M. Alcalá and J. Flores. The work was examined to a depth of 570 metres. The temperature is increasing rapidly. At 435 metres it is 103½° Fahrenheit.

The annual report of the Amparo Mining Co. of Philadelphia, operating in the Etzatlán district, Jalisco, Mexico, shows that the profits for 1909 amounted to ₱668,537.68, and that ₱600,000 were remitted to the Philadelphia office for the payment of dividends and the maintenance of a reserve. The dividends amounted to more than $250,000 gold. The total revenue in the year was over ₱1,500,000. The 50-stamp mill was in commission 344.69 days, crushing 63,398 tons of ore; the bullion and concentrate produced had a value of ₱1,400,017.36. High-grade shipments during the year netted ₱44,048. The cost per ton of ore for mining, milling, and marketing, with general expenses added, was ₱11.24. The company secured a profit of ₱2398 from its Embocada ranch and ₱14,600 from its general store. The ore blocked above the 700-ft. level at the close of the year was estimated at 360,000 tons, and the probable ore below that level at 350,000 tons. There is an old dump of approximately 50,000 tons. The company has ordered equipment that will increase its reduction capacity 100 tons per month. The mill is now treating on an average of 5500 tons per month.

The districts of Etzatlán, Hostotipaquillo, and others in the State of Jalisco have been seriously retarded in their development by the failure of the Compañia Hidroelectrica é Irrigadora to complete its installation and bring in power from the San Lorenzo river. The indications now are that the work will be finished in October. The power company is paying forfeits to the mining companies with whom it was under contract to supply power.

The new cyanide plant of the Seguranza y Anexas at Zacualpán is nearing completion. This will place that company in a position to become an important producer. At the annual meeting the other day the old board was re-elected with the exception of J. C. Doty, who retired in favor of Edwin L. Cole.

A large power-plant is under contemplation to supply the Lucky Tiger and other mines in northern Sonora. The works will probably be near Colonia Morales, on the Bavispe river, although there has been some talk of establishing them at Douglas, Arizona. A meeting was held the other day at Douglas to consider this project, at which were present L. R. Budrow and D. L. H. Forbes of the Lucky Tiger, Walter Douglas of the Copper Queen, John Langton, and E. Gybbon Spilsbury. The plant intended not only to supply power for the operation of the mill put up for the treatment of Lucky Tiger silver and gold ores, but also for the Cinco de Mayo, the Roy, and others. It is also contemplated to supply power for the operation of an electric line to haul the concentrate and high-grade ore from the Tigre district to Izabel, there to connect with the Phelps-Dodge railroad from Nacozari to Douglas.

About 35 men are working on the Montenegro Mining Co.'s property, six miles northwest of Nacozari. A shaft is being deepened to the 600-ft. level. The ores contain gold and silver. W. J. Mortell is manager. The Badger Mining Co. recently shipped 200 sacks of ore from its property, near the old Oso Negro mine. Gold and tellurium have been found in a 7-ft. vein of the old Waldorf mine in the Moctezuma district. The vein runs a long distance and new denouncements have been filed covering it for a length of 2400 metres. Announcement is made that the custom smelter of the Yaqui River Smelting & Refining Co. at Toledo will be blown in before the end of May. The successful operation of this smelter has been made possible by the construction of the Yaqui River branch of the Southern Pacific of Mexico to Tónichi. The plant has been thoroughly overhauled during the last few months. Pumps placed in commission several weeks ago to unwater the shaft of the Creston de Cobre mines have completed the work, and development is being resumed.

The Calumet & Sonora Mining Co. near Cananea has opened rich lead-zinc ore on its 400-ft. level averaging over 80% mineral. Twenty feet have been cut in the drift. Where first found the ore was 11½ ft. wide, and is now much wider. An additional boiler is being added to the mine equipment, and a new blacksmith and machine shop is being erected near the shaft. At the mill a new jig has been installed, also two Deister tables, one Wilfley table, and a grinder. The additional equipment will increase the output of the plant 40%, or will make the capacity 115 tons of concentrate per day. The shipments amount to about 250 tons of concentrate per week. The lead is shipped to Germany, while the zinc goes to the smelter at De Pue, Illinois.

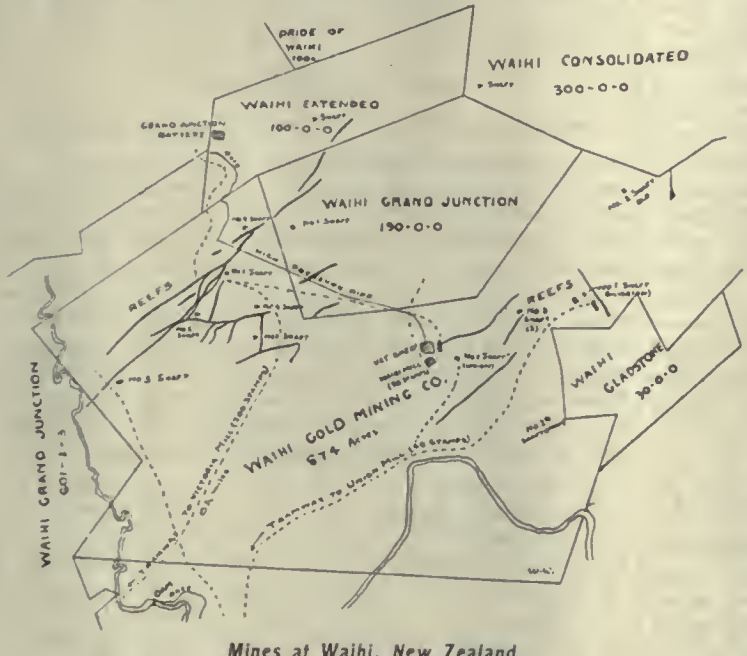
The Department of Fomento has broken ground for the new building, which will be its future home, on the northeast corner of the Avenue Cinco de Mayo and Betlemitas street. This building will include a large testing laboratory, the finest in the Republic.

LONDON

Royal Commission on Safety of Miners. — Conditions in State Quarries.— Waihi Output and Improvements.

There have been in Great Britain several Royal Commissions on safety in coal mines, and indeed one has been sitting now for three years. Another which is to devote itself to the health and safety of persons employed in metalliferous mines and quarries is about to be organized. The minute appointing the Commission issued by the Home Office is, as often happens in an official document, a trifle vague; I do not know whether the adjective 'metalliferous' refers to quarries as well as mines, but I suppose it does not. Metalliferous mines and quarries, with the adjective qualifying both, are not as extensive industries in Great Britain as are coal mines. The chief metalliferous mines nowadays are the ironstone mines in North Yorkshire and Cumberland, and the chief metalliferous quarries are the ironstones occurring in the oolite in Lincolnshire, Northamptonshire, and other east-midland counties. To our own circle of readers Cornish tin mining is the most important metalliferous mining industry of Great Britain, but it is a comparatively small employer of labor. Copper mining is practically negligible, and lead and zinc mining is restricted to small operations in Wales, Derbyshire, and Northumberland. Among the members of the new Royal Commission are R. A. S. Redmayne, chief inspector of mines, and R. Arthur Thomas, of Dolcoath. I take it for granted that general quarrying is included in the scope of the Commission, for R. T. Jones, secretary of the North Wales Quarrymen's Union is on the Commission. The slate quarries of

Wales are in a poor way, having never recovered their foreign trade after the disastrous strike some years ago. Owing to the absence of a protective tariff, French slates are found in use for building purposes not far away from the British quarries. Great Britain also has some excellent granite quarries, notably in the north of Scotland, Leicestershire, and Cornwall, but the Government, when building naval works, usually goes to Norway for the granite, much to the disgust of the British owners. The new Commission is welcome, for it will help to elucidate a much debated subject, that is the health of miners and quarrymen. Since the new law came into force saddling employers with full liability for accident and disease incident to the occupation, disputes have arisen concerning the causes of disease, especially among the Welsh quarrymen. The men blame the dust and fumes of explosives and the employers blame the unsanitary habits of home life on the part of the men. It must be confessed that the men have not been educated to the advantages of fresh air in their homes, and that they seldom ventilate their houses, all of which is not calculated to counteract any unhealthiness of their occupation. As the Commission contains representatives of both masters and men, this subject, among others, will receive full debate and consideration.



Mines at Waihi, New Zealand.

The yearly production of gold and silver at the Waihi, the premier mine of New Zealand, has increased steadily with never a break or setback since operations were started in 1890. The yield for 1909 was 190,912 oz. gold, 1,414,367 oz. silver, obtained from 416,813 short tons, dry weight, and selling for £959,594. The total production to date has been worth £8,180,218, and the total dividends have been £3,810,548. The mining, milling, and development costs during 1909 were £363,851; in addition £36,151 was spent on new plant, £36,963 was allowed for depreciation, and £10,778 has been allocated to the fund for providing electric current as described later. The dividends for the year absorbed £485,161 or 90% on the nominal capital and £38,845 has been provided for income tax. The mine contains a number of lodes, as described in A. M. Finlayson's article on Waihi in the April issue of *The Mining Magazine*. Of the ore mined during 1909, the largest proportion came from levels 7 and 8 on the Martha lode, the amount being just over 200,000 tons. The Royal lode yielded 74,818 tons, the Welcome 48,407 tons, the Empire 45,304 tons, and the Edward 38,430 tons. The reserve on December 31 was estimated at 1,335,586 tons. The metallurgical equipment comprises 330 stamps and 15 tube-mills. The plant is divided into three separate mills, the Waihi with 90 stamps and 4 tube-mills, the Victoria with 200 stamps and 10 tube-mills, and the Union with 40 stamps and 1 tube-mill (the latter put in commission during August last). As mentioned above, the company has a scheme on hand for generating electricity at Hora Hora rapids, 50 miles away, and a license has been obtained from the Government to erect a plant of 10,000 hp. capacity. The Waihi forms an excellent example of the occasional idiocy of English shareholders. For some unknown reason, some of them take a delight in opposing and criticising. For instance, at present, some have opposed the scheme for utilizing the Hora Hora falls, and say that profits should not be allocated for this purpose. There was not the ghost of a reason for their arguments, and the agitators had no knowledge of their subject. The fact is that the directors do not see fit to worry about stock exchange business.

NEW YORK

Government Injunction and Speculative Market. — Copper Production.—Guggenheim Dividends.—Heinze and United Copper.—San Cayetano.—Nipissing. — United Verde.

Market conditions in the East were felt to be improving, the general public was firm in the belief that, with the placing of large blocks of railroad bonds abroad, higher prices were to rule; in fact, everything was in readiness apparently for a strong upturn, when the action by the Federal Department of Justice, in securing an injunction against the leading railroads of the West, prohibiting them from increasing freight rates, caused a hasty abandonment of all market plans and precipitated a wave of liquidation that carried the market almost to the point of demoralization. No action by the present administration has been so much discussed or felt to be so radical. At the moment the underlying effort of the market is to regain its equilibrium, to get its bearings after sustaining a hard blow. There is a noticeable absence of any attempt to discredit the administration by questioning of motives. The entire sincerity of the Government's action is evidently admitted; how far reaching its effect may be is another question. Such summer campaign plans as may have been laid are evidently abandoned and a struggle for real regulation of the railroads is already launched. Stagnation already holds the issues not being liquidated, and after such selling movement shall have fully run its course a longer period of inactivity must ensue. The copper situation is not improving as much as was hoped. Exports for the month were 41,664,000 lb. which, while an increase over April export of 26,124,000 lb., does not indicate any marked improvement in the forthcoming figures of the Producers' Association. Butte production, it is true, shows a slight decrease, but some of the porphyries are known to have broken all previous records in the matter of output. The Phelps-Dodge properties and the Calumet & Hecla are not crowding production, the latter is now outputting about 5,500,000 lb. per month, or at the rate of 65,000,000 per annum, and is earning about $30 per share. The last quarterly dividend was $8 per share and the current dividend which is to be declared within a few days will probably be something less; $6 per share is expected. While the Butte production shows a slight decrease this is more to be attributed to the recent changes made in the camp than to any definite attempt to lessen production. Figures on the Nevada Consolidated production are not as yet available, but it is understood that the company made more copper than in any single previous month. Utah Copper output for May was 7,902,643 lb. Dividend declarations have been made by the entire group of Guggenheim companies. The Guggenheim Exploration Co. is paying 2½%; the Yukon Gold Co. 10c. per share; the American Smelting & Refining Co. 1% on the common stock and 1¾% on the preferred; Nevada Consolidated 37½c. per share; Utah Copper 75c. per share; Cumberland-Ely 10c. per share. It is worth noting that some of these payments may be paid out as dividends four times before reaching the pocket of the individual stockholder. Practically all of the Cumberland-Ely dividend will go to Nevada Consolidated; half of Nevada Consolidated's disbursement goes to Utah Copper; the Guggenheim Exploration Co. owns a large

holding in Utah Copper, so that it may be seen that a large part of the Cumberland-Ely profits will be paid out three and four times as dividends before reaching the 'ultimate consumer'. F. Augustus Heinze is to be counted on to do the unexpected and the sensational. During the recent court proceedings, when Mr. Heinze was on trial for alleged misuse of the funds of the Metropolitan National Bank, every effort was made to get at the inside history of United Copper, and to get some kind of an inventory of its assets, but without avail. Now that the fight is over and Heinze free, until further cases pending against him are brought to trial, he springs a surprise on the United Copper shareholders by giving them a rough inventory of their holdings. Mr. Heinze lists as United Copper assets: practical control of the Ohio Copper Co.; $75,000 par first-mortgage bonds of the Ohio Copper Co.; control of the Stewart Mining Co., of the Coeur d'Alene, held through the Montana Ore Purchasing Co.; two-thirds of the capital stock of the New York & Pittsburg Coal Co., which owns about 10,000 acres of coal land in Pennsylvania, figured to contain coal worth $17,940,000 net; there are some miscellaneous properties in Montana, including the Basin Reduction Works, and an undivided half interest in 540,000 acres of timber land in northern British Columbia. Mr. Heinze promises that, as soon as he can gain possession of the United Copper books, a complete financial statement will be issued and a plan for re-financing the company will be submitted to the shareholders. The Ohio Copper Co. must now be counted as one of the producing porphyries. For the quarter ended March 31, Ohio shows a net profit of $21,670. The ore now being handled is probably lower in average copper content than that of any of the low-grade milling coppers, as it runs but about 14%. On this grade of ore, however, the management claims to show a net of 75c. per ton on the present copper market. The last of the Ohio Copper bond issue, some $754,000, is to be sold; of this amount about $500,000 will be utilized to take care of outstanding obligations, while the balance will be expended in the completion of the last two units of the mill. The increase in the capital stock of the Ray Con., for the purpose of absorbing the Gila Copper Co., has been authorized by the special meeting of the shareholders, and the holders of Gila are now notified that exchange will be made up to July 1, on the basis of one share of Ray for three shares of Gila. The special meeting of the San Cayetano Mines, Ltd., was held this week and the proposed increase in the capital stock from $250,000 to $1,500,000 was authorized by the shareholders. Active development of the San Cayetano property at Guanajuato, by the Lewisohns, who control it, is expected, as soon as the financial plans, following upon the increase in capital stock, are completed. The work of overhauling the Yellow Jacket mill and re-opening the mine in Lemhi county, Idaho, has been begun by J. B. Hastings, who is in charge. The Yellow Jacket property has lain dormant for some years, being tied up in the estate of the late John E. Searles of the American Sugar Refining Co. The property was recently taken in hand by the Proprietary Mines Company of America and vigorous development of the immense low-grade orebodies is to be prosecuted under Mr. Hastings' management. A special meeting of the directors of the Nipissing Mines Co. has been called for next week, and it is expected that an interim dividend of 10% will be declared and paid; this will call for a distribution of $600,000, in addition to the regular quarterly dividend of 5% and 2½% extra, which will be declared at the regular quarterly meeting held later in the month. The payment of this interim dividend is made because of the assurance of large income from the present ore reserves, increased by the recent discovery of several large veins, and also because the company has a rather unwieldy surplus of about one and a half million dollars, which the management feels should be distributed to the shareholders, in view of the large earnings certain to be made within the next few months. The spirit shown in this regard ought to go far toward redeeming Nipissing from the stigma under which it has labored since the days of the Hammond-Guggenheim episode, when the collapse in the shares gave Cobalt a setback from which it has never fully recovered. W. A. Clark has not retired from the copper world, as is evidenced by his drawing this week his regular monthly dividend of 75c. per share on practically all of the stock of the United Verde Copper Co. There was quite a little interest created, some weeks since, by the sale at auction in New York of 500 shares of United Verde. The stock was evidently purchased at what was thought to be a bargain price by some speculator, who has since been busily engaged in trying to get his money back by loan or sale, and who has been greatly surprised to learn that, inasmuch as Mr. Clark refuses to make any bid for this block of stock, he has no market on which to sell or to give the shares a collateral value. Whether good, bad, or indifferent, the investment is plainly a permanent one, unless the recent purchaser takes his way back to the auction room, now as a seller instead of a buyer. Greenwater Copper Mines & Smelters Corporation is a concern into which a great number of Greenwater promotions were merged. It represents the investment of hundreds of thousands, and, since Greenwater has been abandoned as a mining camp, the company now has as its only asset a cash fund of some $240,000, the remnant of several times that sum. A fight for the control of the treasury has recently developed.

BUTTE, MONTANA

Anaconda Output.—May Production. — Butte Reduction Works.

The smelters of the Anaconda Copper Mining Co. are being operated to full capacity, which does not indicate any intention of shutting down mines or curtailing production in the Butte district on account of alleged overproduction and inability to compete with the so-called low-cost producers. The Washoe smelter is producing copper at the rate of about 18,000,000 lb. per year, the Great Falls smelter between 7,000,000 and 8,000,000, and the East Butte, including the copper from custom ore, about 1,000,000. The Clark smelter produced, including the Clark product and that of the Tuolumne company, about 1,500,000 in May. The total production of various companies in May was:

Companies.	Copper, lb.
Boston & Montana	8,200,000
Anaconda	8,000,000
Butte Coalition	3,040,000
North Butte	2,280,000
Original	1,190,000
Butte & Boston	1,100,000
East Butte	800,000
Trenton	770,000
Butte-Ballaklava	558,000
Tuolumne	500,000
Parrot	340,000
Miscellaneous	325,000
Total	27,978,000

The Anaconda Copper Mining Co. has taken possession of W. A. Clark's Original and Stewart mines in the Butte district, which were recently purchased. The formal change of ownership took place immediately after midnight on May 31, and the miners went to work under the new ownership the following night, after which all ore that was mined was shipped to the Washoe smelter at Anaconda. The smelting department of the Butte Reduction Works will be run for three weeks or a month on the ore on hand and in cleaning up the old plant, after which it will be closed. The concentrating department, which has been leased back to W. A. Clark, will continue to operate on the Clark and custom zinc ores. The smelting department will not be dismantled and the furnaces will remain intact. Connections will be made between the Original and Gagnon mines, and it is anticipated that eventually but one of these shafts will be used for mining, and that the old incline shaft on the Gagnon will be abandoned when the new Gagnon vertical shaft is completed. The latter is 1000 ft. distant from the old shaft and has reached a depth of something more than 700 ft. How the closing of the Butte Reduction Works will affect some of the independent mines which have been shipping to that smelter is not known. The Tuolumne company and the Keating Gold Mining Co. have been sending their ore there.

General Mining News

ARIZONA.

COCHISE COUNTY

The Black Diamond Mining & Smelting Co., which owns a group of claims in the Dragoon mountains, is to resume operations after an idleness of two years.——There are 100 tons of ore on the dump at the Swain property that will average 25 to 30% lead, and 5% copper, with some silver and gold.——The water is being lowered slowly in the Tombstone Consolidated, and it is thought that the work will be completed by the end of summer when the old drifts will be retimbered and the stopes opened.——The west drift from the bottom of the shaft at the Whitetail group, in the Paradise district, is in ore assaying 10% copper.——Work is to be resumed this month on the Bradshaw-Arizona group in Round valley.——The flow of water in the south drift of the Mary property at Courtland is still so heavy that the company has not resumed work in that portion of the mine. The work of prospecting the Silverton with a diamond-drill from the Mary workings is still being carried on.

GILA COUNTY

(Special Correspondence).—A stringer opened by a cross-cut on the 660-ft. level of the Williams shaft in the east part of the National Mining Exploration property has been shown by 100 ft. of driving westward to be fully 30 in. wide. The copper content of the ore is increasing with development, due largely to the association of considerable copper glance with the carbonate.——The property of the Cole Development Co., including 17 claims, situated 20 miles west of Globe, has been taken under bond by the Little Miami Copper Mines Co., which was recently organized with headquarters in New York. The purchase price includes a cash payment distributed over several months and 75,000 shares of Little Miami stock, recently listed on the New York exchange.——A 60-day option on 20 claims, owned by the Dixon Copper Co., and situated 10 miles west of Globe, has been taken by John O'Keeffe, of El Paso, who is said to be acting as representative of Pittsburg capitalists. The agreement provides that if the option is exercised, the purchasers shall organize a development company capitalized at $3,000,000, with stock at $1 par, and turn over to the owners, in addition to a small cash payment, 750,000 shares of the new company's stock.

Globe, June 4.

PIMA COUNTY

An average sample of the ore taken from the New Gold Discovery mine, six miles southwest of Tucson, gave 15% lead, 14 oz. silver, and $8 gold per ton.

PINAL COUNTY

F. S. Hoyt, superintendent for the Superstition Mountain Mining Co., has joined J. W. French in the development of a group of claims one and a half miles northwest of Florence. A recent sample sent to the El Paso smelter netted $6.30 per ton. A 25-hp. gasoline hoist, compressor, and drill, are to be installed at the La Coronado mine, in the same district, an order for the machinery having been placed with Fairbanks, Morse & Co. The shaft is now down 260 ft., and the new equipment will enable the company to sink to the 500-ft. level by which time it is thought the sulphide ore will be opened.

YAVAPAI COUNTY

The shaft of the Commercial Mining Co., in the Copper Basin district, is now down 100 ft., the main efforts of the company being centered at this point.——John Malm is inspecting the plant of the Rigby Mining & Smelting Co., at Mayer, with the idea of remodeling the smelter and installing the Malm process as worked out in the test-plant at Denver.——The vein in the face of the drift at the Independence mine, in Chaparral gulch, is over 5 ft. wide, and assays about $9 per ton. A cross-cut is soon to be started toward the Little Jack vein which will be opened at a depth of 80 ft.——A new pump is to be installed at the Jerome Verde copper mine, near Jerome, as the flow of water in the bottom of the shaft has been extremely heavy lately. A contract has been closed with the Arizona Power Co. for power to raise the water.——A wagon-road is being graded from the Pacific copper mine to Harrington, and when this is completed the company will install a large hoist and air-compressor. There is a good showing of copper ore on the group and it is the intention of the operators to commence shipping to the Humboldt smelter at an early date.

YUMA COUNTY

Plans are being considered by the Clara Consolidated Mining & Smelting Co. for the construction of a sampler at Parker to handle the silicious ores tributary to that district. These ores are necessary to flux the Clara Consolidated ore and have been found in a number of properties in the Parker district.——L. A. Dunham, who recently secured a bond on the Horn mine, south of Parker, has started a cross-cut adit that will tap the ore in about 400 ft., and is installing machinery to hurry the work. About 1200 ft. of development has been done on the property opening some good ore.

CALIFORNIA

AMADOR COUNTY

The 10-stamp mill being erected at the Monte de Ora mine, near Plymouth, is nearly complete and will commence crushing the ore about the middle of this month. The mine, which is operated by A. P. Morgan, has been well prospected and a large amount of good milling ore opened.——The conditions at the Keystone Consolidated have not changed and there is no prospect of an early resumption of activities.

BUTTE COUNTY

The weekly clean-up of the dredge of the Butte Creek Consolidated Dredging Co. last week amounted to $4700, the week before being $2800. The dredge is now working upstream, and is reported to be in a good grade of gravel.

EL DORADO COUNTY

The drift at the Last Chance mine, at Coloma, which has been operated for the past year by Albert Shafsky and L. N. Stricker, is in fair looking quartz and it is thought by the operators that a pocket for which the mine is noted will be opened in a short distance.——The Rising Hope gravel mine is being thoroughly prospected by J. R. Partridge and G. W. Englehardt.

INYO COUNTY

An adit is being run at the Golden Siren claims at Gold Storage to tap the shaft at a depth of 135 ft. C. D. Adamson, of the Golden Siren company, has staked several other claims in the same district, and will probably organize a company to build a mill that will crush the ore from both properties.——Recent work at the Casa Diablo mine, 20 miles north of Bishop, has opened some high-grade ore and the 30-ton mill has been kept busy night and day. The company is planning to install new machinery that will bring the capacity up to 100 tons per day. C. A. Fohrman is manager.——On a recent lot of ore from the Yucca mine, at Darwin, run through the old Coso mill, the clean-up amounted to 59.7 oz. gold, 18.8 oz. silver, and several tons of concentrate that assayed $294 per ton. The Yucca is one of the newer properties in the district being 1½ miles from the old Coso, and has only been opened to a depth of 160 ft. with a small amount of work on the vein.——Two shifts are now working on the property of the Wilshire Bishop Creek Co., and the water has been lowered below the second level which is 290 ft. from the surface. The compressor and pipe-line which were damaged by a snowslide last winter have been repaired, and the pump will be lowered to the second level preparatory to resuming work there.

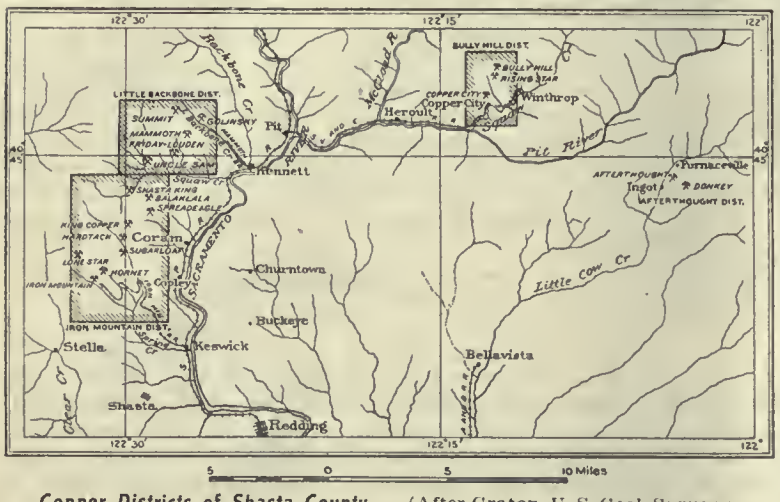
SHASTA COUNTY

The Evening Star mine, in the Old Diggings district, which was taken over recently by German capitalists, is shipping about 400 tons of ore per month to the Mammoth smelter.——No definite settlement has been made in the case of the Forest Service against the Bully Hill Mining & Smelting Co., at Winthrop, and it is reported that the smelter will be shut down on July 1. The smelter is situated in a district where there is neither timber nor agricul-

tural land to injure, but if the Government persists in its efforts against the company, the plant will be closed and the ore forwarded to the Coram or Mammoth smelter. Until recently the Bully Hill smelter had not been involved in the smoke troubles.

SIERRA COUNTY

Charles R. Thompson, who has a bond on the Young America mine, near Sierra City, is at the property with a party of engineers and it is reported that operations will



Copper Districts of Shasta County. (After Graton, U. S. Geol. Survey.)

be resumed on the group. The mill which crushed the ore from the upper levels was partly destroyed by fire a few years ago and has never been re-built.

SISKIYOU COUNTY

Preparations have been made to resume work at the Yellow Butte mine, 12 miles east of Weed. The company owns 320 acres of patented land where a shaft has been sunk on the vein to a depth of 350 ft. opening several bodies of chalcopyrite ore containing gold and silver. In all there has been done about 1000 ft. of development. L. D. Ball is manager.

TRINITY COUNTY

(Special Correspondence).—About all of the smaller hydraulic mines are preparing to make their clean-ups as this season is shorter than usual. The La Grange and Union Hill mines will run for some time yet.——An important mining deal has been made by the bonding of the Fields Consolidated Quartz & Placer mines to a syndicate of French capitalists who have had their representatives on the ground and found everything satisfactory. The holdings consist of 400 acres of quartz and timber locations with several quartz veins assaying from $7 to $18 per ton, and 1152 acres of gravel which pans from 14 to 25c. per cu. yd. The water rights take in the north and south forks of Indian creek and a head of 3000 in. of water for nine months in the year is available. The present ditch will have to be extended about ten miles to reach the gravel which has heretofore been unworked for lack of water.

Weaverville, June 6.

A contract has been let to haul the 600 tons of machinery for the new mill being erected at the Headlight mine, at Carrville, from Delta to the mine. When completed the mill will contain 40 stamps.——The Trinity River Mining Co.'s tunnel, a mile above Lewiston, is still occasioning considerable trouble by leaking. The company will place a cast steel pipe 8 ft. in diameter for 100 ft. at the lower end of the tunnel in an effort to control the flow.

TUOLUMNE COUNTY

(Special Correspondence).—The force at the Grizzly group of mines, near Tuolumne, is being increased and henceforth will be divided into three shifts.——The new 5-stamp mill at the property of the Phoenix Lake Mining Co., near Confidence, has been started.——Machinery is being installed at the Potato Ranch gravel mine, near Phoenix lake, and the property will be worked on a larger scale than at present.——Twelve men are employed at the Clio cleaning out a drift and making other necessary preparations for the resumption of operations.——A pack-train is bringing ore from the Nervi mine to the Golden Era mill.——Operations are soon to be resumed at the Longfellow mine and the shaft will be sunk to 1000 feet.

Tuolumne, June 4.

George Grant and G. W. Rowse, who have been developing the Old Dominion property near Columbia, opened a shoot of high-grade ore in a cross-cut from the main drift, the vein being about 4 ft. wide. The Dutch mill is running steadily crushing 100 tons of $20 ore per day.——It is reported that the App shaft is to be sunk another 300 ft. from the present working which is 1300 ft. below the collar of the shaft.——The property of the Pereira Mining Co., near Jamestown, was unwatered a few days ago and examined by P. Koppen, president of the company, and M. O'Brien, of San Francisco.——A contract has been let to sink the shaft at the Karnac another 50 ft., which will take it to the 160-ft. point, where a cross-cut will be run to the vein. The vein at a depth of 100 ft. shows 2 ft. of high-grade ore.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—It is stated that work will soon be put under way on the Buchanan mine, situated on Leavenworth mountain, at Georgetown. The property was a former heavy producer of high-grade ore.——J. W. Crandall, leasing through the Scepter adit 2800 ft. from the portal, has opened in a stope on the Astor vein a streak of ore 12 in. wide that assays from 300 to 500 oz. in silver per ton, with from 15 to 20% in lead. Shipments are to be started next week.——A. L. Stephens, manager for the Homestake Gold Mining & Milling Co., will award another contract during the coming week for the driving of the Homestake adit another 100 ft.——A contract will be awarded in a few days by G. W. Boyce for the sinking of the shaft on the Anamosa vein another 200 ft. This shaft is being sunk from the Rochester adit level, 1200 ft. from the portal.——Work of construction on the new 100-ton mill for the Conqueror Mining & Milling Co. is well under way. W. S. Pryor, the manager, expects to have the plant in operation within 60 days.——A 40-hp. boiler and a 30-hp. double-friction hoist has just been placed in position at the shaft of the Jersey Blue Mining Co., situated in Daily district.——A dam is being constructed by the Bard Creek Mining Co. for storage of water to generate electric power. N. Nelson is manager.

Idaho Springs, June 4.

GUNNISON COUNTY

Henry Cole and associates who are operating the Gold King mine at Silisville shipped a carload of ore recently that assayed 3½ oz. gold per ton.——The mill at the Maple Leaf is reported to be making a good saving both on the plates and the tables, and the operators are preparing to sink the shaft to the 1000-ft. level.

LAKE COUNTY

Work has been started by the construction crew of the Denver & Rio Grande railway on the lower side of the track that is to connect with the lower shaft of the A. Y. & Minnie property in California gulch at Leadville. As soon as this switch is completed hoisting through this shaft will be started. Formerly this shaft was used for pumping but with a little improvement can be adapted for hoisting. In the meantime the work of repairing the buildings that were destroyed by fire a short time ago is being carried forward and new machinery has been ordered to replace that which was too badly injured to set up again.——William Jones, who opened a large body of zinc ore on the 225-ft. of the Robert E. Lee mine last season, has opened several stopes and will ship a carload of ore per day.——James E. Condon and associates who are operating the Fraction property on Fryer hill are hoisting waste from the 250-ft. level and cross-cutting to open the orebody that was worked in the levels above.——Two sets of lessees are working at the old Dunkin mine.

OURAY COUNTY

The Camp Bird mine is working a larger force at present than it has for some years and will soon add to this to carry on the extensive development outlined by the management.——The mill at the Revenue is being remodeled and new living quarters erected. The company is now working 150 men and expects to add 100 shortly.——The San Antonio, at Red Mountain, was opened the latter part of May and shipping resumed.——The connection between the drainage adit at the Calliope and the old workings has been completed and mining operations started in the stopes.

SAN JUAN COUNTY

The W. B. Lowe Mining & Milling Co., which purchased the Yukon group of claims near Silverton last November, is preparing to open the property on a large scale, and is now grading for the foundation of a compressor and power-plant. The property is developed by two long adits, one of which is now in 2600 ft., having cut a number of veins containing gold, silver, copper, lead, and zinc. This adit obtained a vertical depth of over 1400 ft. The mine is equipped with a 100-ton mill and is expected to become a big producer this season.——The Danville Mining & Milling Co., operating in Cunningham gulch, commenced shipping for the season by forwarding a car of ore to the Durango smelter. The company is now working 26 men.

TELLER COUNTY

An orebody from 8 to 12 ft. wide has been opened on the 800-ft. level of the El Paso mine by the sub-lessees, Edward Carey and Homer Trees. The ore was cut by a raise and will average $30 per ton.——Ward & Hill, lessees of the Pharmacist mine on Bull hill, are shipping 100 tons per week of ore that assays about $20 per ton.——The third unit of the Portland Gold Mining Co.'s new mill was placed in operation a few days ago, and is now running eight hours per day. The capacity of the unit is 100 tons per day, and this amount will be put through the mill as soon as the machinery is running smoothly.——Charles Crowder has secured a lease on a portion of the Burns claim of the Acacia Gold Mining Co., and will open the ground from the eighth level of the South Burns shaft. The block is in new ground and extends to the fourth level of the old Burns shaft which has a production record of over $1,000,000.——A shoot of high-grade ore which is reported as the richest ever opened in the property, has been found on the 1400-ft. level of the Golden Cycle mine.——A company of local operators has secured a lease on the Hoosier mine and will sink the shaft from the 800-ft. level to the 1000. The Hoosier has an excellent record and good ore has been proved below the 800 by a winze sunk on the shoot.

MONTANA

JEFFERSON COUNTY

At the Boston & Corbin properties sinking has been resumed and the shaft will be put down from the 700 of the Bertha mine to the 1500-ft. level. A cross-cut will be run at every 200 ft., and the orebodies which have been developed on the upper levels will be worked. The electrical equipment has been completed and will be in full operation within the next few days. The new electrically driven hoist has a capacity for sinking to a depth of 2500 ft. The new surface equipment at the London-Corbin has been installed. A head-frame has been completed, the hoist started, and sinking resumed in the bottom of the 60-ft. shaft.

SILVER BOW COUNTY

(Special Correspondence).—All of the Anaconda mines are in unusually good condition, and are producing at a rate that has not been equalled in several years. It is understood that more men than ever are employed, and that the Washoe smelter is producing copper at a rate of about 18,000,000 lb. per month, while the output of the Great Falls smelter runs between 7,000,000 and 8,000,000 lb. per month. The Clark reduction works have turned out about 1,500,000 lb. per month, which included the Tuolumne and other custom copper. The Pittsmont smelter produces the remainder of the Butte product, amounting at present to close to 1,000,000 lb., which includes East Butte, Butte-Ballaklava, and other custom copper.——The Anaconda company is not pushing development at present, as the reserves are far ahead of requirements. Shaft sinking is going on at the Gagnon, Badger State, Right Bower, and Belmont, although just at present no work in the shaft is being done on the Right Bower, where the current work consists of driving on the 200 and 500-ft. levels. The Badger State shaft is down a little more than 1800 ft., and the Belmont over 1400.——A cross-cut has been run from the High Ore 2800-ft. level to a point under the shaft of the Anaconda mine, the latter being 2400 ft. deep. A diamond-drill opening was made between the High Ore cross-cut and the Anaconda shaft through which the latter has been drained. Eventually, as the material is needed for waste and filling, the shaft will be raised, thus giving the Anaconda a depth equal to that of the High Ore, through which the former will hereafter be drained.

Butte, June 6.

NEVADA

ESMERALDA COUNTY

The 3-compartment shaft of the Florence mine, at Goldfield, has been retimbered between the 580 and 350-ft. levels and is now being enlarged to three compartments from the 350 to the surface. When this is completed development will be started at the 425 and 500-ft. levels and sinking continued to the 1000-ft. point.——The Goldfield Consolidated is having plans of an extensive fire-fighting system drawn that will protect the entire plant, and in the mine bulkheads are to be placed so any portion of the workings can be sealed on short notice. The company has installed a bonus system in the underground work which will give the men an opportunity to increase their wages according to their ability.——Work on the 360-ft. level of the Lind lease, on the Booth and Oro claims, has opened 4 ft. of milling ore with ten inches of high-grade.——The shaft at the Nevada Victor, three miles west of Goldfield, is down 100 ft., and will be continued to the 200-ft. point where it is expected to open the vein.

NYE COUNTY

The main west drift on the 400-ft. level of the West End property at Tonopah and the raise 50 ft. from the face of the drift have both broken into ore of good grade. The discovery was made west of the fault that has previously cut off the value in the ore and 500 ft. from the shaft, and is important as there is a large amount of ground in that portion of the mine that has been regarded as barren but may now prove productive.——The Montana Tonopah during May produced about $35,000 worth of bullion, shipped 112 tons of concentrate, and milled 4500 tons of ore which was an increase of 200 tons over the April crushing. Underground the east drift on the intermediate level above the 390 shows a small improvement, the vein now being 12 in. wide.

WHITE PINE COUNTY

(Special Correspondence).—A considerable amount of structural material for the steel head-frame has been unloaded from the cars and stored near the Giroux shaft. While the old Alpha shaft of the Giroux group was sunk to a depth of 1200 ft. in the porphyry zone and cut a strong flow of water there, the new shaft was sunk off the mineral zone, in solid limestone, and at the depth of 1200 ft. opened no channels of water. There is now 200 ft. of water in the Alpha, and after the pumps have been installed at the 1200-ft. station of the new shaft a cross-cut is to be driven from this station into the porphyry zone to tap the water of that territory and drain it. The plan is to have ample facilities for handling the accumulated surplus, and after the lower workings of the Alpha have been drained it is believed the problem of keeping under control the natural flow of water will not be serious. The intention is to sink the new shaft to greater depth. The surface boundary lines of the Giroux holdings are being shown by establishing 125 corner posts, each of which consists of an iron pipe, 4 in. diameter, 4 ft. long, with two cross-rods at the bottom, set in a concrete base, 2 feet square and 3 feet deep. The pipe is filled with concrete, and has an iron plug screwed into the upper end; the top of the plug is lettered with the name of the claim, number of survey and corner, date and name of the com-

pany—all cut by a steel die. Beneath the iron plug and next to the concrete is a copper plate containing the same data. This work is being performed by Haff & Colwell Bros.

Ely, June 3.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—Probably the most encouraging development in the Socorro mines is the value of the orebody on the 600-ft. level east of the Little Fannie vein where the ore is 6 ft. wide, and assays $40 per ton.——The Ernestine Mining Co. was forced to curtail its output during the past week on account of lack of water for the mill, only 563 tons of ore being crushed and 45 sacks of concentrate shipped. The number of men underground has been increased and more extensive development is being carried forward.——Work has been started in the shaft of the Deadwood mines and sinking will be continued to a depth of 600 ft.——The Enterprise Mining Co. has let a contract to advance the drift 50 ft. on the vein which is over three feet wide.

Mogollon, June 3.

OREGON

BAKER COUNTY

It is reported that a body of free-milling ore has been found in the old Bonanza mine, and that the property may be re-opened.——The cross-cut adit at the Zenith property is in over 700 ft., and is being advanced to open the Putnam vein which it is expected to intersect within the next 50 ft. A 12-ft. vein that assayed $11.60 per ton was recently cut by the adit but no development work has been started on this as the Putnam is the main vein on the group. ——The Buffalo-Monitor mine made the first shipment of ore to the Sumpter smelter under the new management. The Buffalo-Monitor is on Buffalo mountain about six miles from Granite and in the past has shipped a considerable tonnage of high-grade ore to the smelter.

UTAH

JUAB COUNTY

The shaft at the Bradley is now in 200 ft., and grading has been started for the new hoist. The Opohongo is shipping three carloads of ore per week which is being mined on the 350 and 400-ft. levels.——The Victoria Mining Co., at Eureka, is to resume sinking in the bottom of the 500-ft. shaft and continue it to the 1000-ft. level. Sinking has been stopped at the 500 for some time as the company operated through the Grand Central workings, but now the shaft will be completed and a large hoist installed. The work is done under J. C. Sullivan.——At a meeting of the directors of the East Tintic Development Co. an assessment of 1c. per share was levied and it was decided to suspend operations at the mine until a considerable revenue be derived from this assessment.——The directors of the Yankee Consolidated levied an assessment of 2c. per share which will be delinquent June 24.

WASHINGTON

STEVENS COUNTY

The Germania tungsten mine in Cedar canyon, 28 miles west of Springdale, is producing regularly, and it is announced that the Tungsten King property, 11 miles north of Deer Park, will begin shipping in 30 days, while the Baird-Harrison property is expected to enter the list before the close of the year. The Germania company owns 640 acres of patented land and 35 mineral claims. Though its property is known to be traversed by five veins, development work has been confined to one, which has been opened by 3000 ft. of development. These workings show a quartz vein having an average width of two feet, well mineralized throughout with tungsten in the form of wolframite, with occasional shoots of high-grade ore. The property is equipped with a 40-ton mill, which produces five grades of concentrate, varying from 58 to 74% in tungstic acid. Steady production at the mill began 60 days ago, since which two cars of concentrate have been shipped, while a third is being loaded. The two cars shipped aggregated 53 tons, and the net returns were more than $600 per ton or upward of $30,000 for the two cars. The ore is marketed through an agency at Cassell, Germany, to the Krupps of Essen, and is shipped to Hamburg, the freight rate being $18.60 per ton, of which $2.60 covers all costs after New York is reached. The Tungsten King claims, owned by the Deer Park Mining Co., is the oldest property in the district and consists of 80 acres of school land leased from the State for 30 years. A. E. Barnes announces that a mill, now in course of construction, will be in operation in 30 days, producing from 30 to 60 tons of concentrate per month. The company is capitalized at $250,000, and that sum, to be paid in installments during three years, was recently bid for the property by a mining man of Spokane.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—The leading feature of the mining situation at Nelson this week is the beginning of shipments from the Consolidated company's Queen Victoria property, with an initial consignment of 61 tons. This property though low grade will permit of a big production, as the orebodies are extensive.——R. H. Leach, managing director for the Britannia Mining & Smelting Co., and his associates, have secured the Clyde-Belt group of claims.—— The ore shipments from the Granby company's mines at Phoenix passed the 500,000-ton mark with the output of the last week. Work continues steadily at the mine and the shipments are being kept up to a high average.——The British Columbia Copper Co. is now about ready to resume smelting operations at the Greenwood smelter and will start up any day. It is expected that the 25,000-ton test shipment from the Rawhide claim of the New Dominion Co. will be put through the Greenwood plant at an early date. ——The Contact group of claims on Moresby island has been bonded for $100,000 to Hugh Cannon, of Grand Forks. Butte capitalists are interested and development work is to be commenced very soon.

Rossland, June 4.

ONTARIO

In the cross-cut northeast from the 222-ft. level of the No. 2, one of the principal veins of the Coniagas mine, at Cobalt, was cut a few days ago, showing 4 in. of smaltite ore with considerable native silver. This is the first of the important veins to be picked up on this level though it is expected that the No. 6 vein will be opened in a short distance.——The Campbell & Deyell sampler, near the La Rose property, has been completed and is now in a position to handle custom ore. The plant is entirely automatic and is designed to handle 30 tons of ore per day.——The Argentum Mines Co., which is operating the Foster property, is to install a Calyx drill to prospect below the lower levels of the mine.——Four inches of ore that will average 4000 oz. of silver per ton was opened by the No. 10 cross-cut on the 100-ft. level of the Crown Reserve mine.——Convinced that many of the veins on the Nipissing property are not found even with the thorough method of trenching now used the management has decided to install two large turbine pumps at the lake and wash away the over-burden so the surface of the rock can be carefully examined. As there are 846 acres in the property the undertaking will occupy considerable time.

MEXICO

SONORA

At the Calumet & Sonora, two miles north of Sonora, the company is stoping on a 4-ft. vein of lead-silver-zinc ore on the 60-ft. level. At the mill the company is installing a new classifier, jig, one Wilfley, and two Deister tables which is expected to raise the output of the mill 40%.——The Lucky Tiger is shipping approximately 10 tons of concentrate per day.——The Pilares Mining & Development Co., and the Purdy Gold & Silver Mining Co., have commenced operations and will be shipping high-grade ore in a short time.——Since the installation of the new pumping plant at the Creston de Cobre property, 30 miles west of Hermosillo, the work of cross-cutting has been going steadily forward. The company is planning to install a reduction works at the mine in a short time.——An aerial tramway will be installed shortly at El Tigre, and a central power-plant is contemplated.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

JAY A. CARPENTER is at Millers, Nevada.

J. CLAUDE JONES visited San Francisco this week.

E. B. KIRBY was in San Francisco and Los Angeles this week.

SUMMER S. SMITH is at Jackson, Amador county, California.

ALLEN H. ROGERS, of New York, is at Santa Rita, New Mexico.

E. GYBBON SPILSBURY has returned to New York from Arizona.

WALTER HARVEY WEED has been at the Minas de San Pedro, Chihuahua, Mexico.

ARTHUR LAKES is making geological examinations in Arizona and California.

B. R. BINN has charge of the mines of the Sterling Borax Co., at Lang, California.

NEWTON S. KELSEY has gone to the Atlin district, British Columbia, to examine dredging ground.

F. A. CRAMPTON is manager at the mines of the Arizona Copper Belt Mining Co., Wickenburg, Arizona.

ARTHUR LAKES, JR., of Denver, is making mining and metallurgical examinations in Summit county, Colorado.

H. HENDRICKSON is now assistant engineer for the Maxwell Land Grant Co., with headquarters at Baldy, New Mexico.

JAMES W. ABBOTT, who has been in the hospital at Salt Lake, has recovered and is again on duty at Pioche, Nevada.

E. C. ENGELHARDT has left the Mary Murphy G. M. Co., of St. Elmo, Colorado, to become superintendent for the Cooke M. & R. Co., Cooke, Montana.

E. PAUL JONES, recently chief engineer for the Risdon Iron Works, has become superintendent for the Yuba Construction Co., Marysville, California.

WILLIAM LETTS OLIVER has resigned his position as superintendent of the cyanide department at the North Star mine, Nevada county, California, to enter private practice. He will open an office in San Francisco.

MAY COPPER REVIEW

By M. E. APPELBAUM*

During the early part of May the metal established a new low level, since the mark made during the panic of 1907. However, when the 12½c. delivered 30 days level was reached, tremendous purchases were made by domestic as well as European consumers and this caused a sharp rally to 12¾c. delivered 30 days, at which price the metal held firm during the balance of the month. While the domestic consumers are using tremendous quantities of copper, nevertheless the new orders which they are getting are insignificant and unless business shortly improves, the domestic consumption cannot keep up at the rate established. Consumers have orders enough on hand for the next month or two. So far as the European situation is concerned, the visible supply has decreased during the month about 3000 gross tons. Exports during the month of May were in the neighborhood of 50,000,000 lb., which, together with 68,000,000 lb. domestic deliveries, represents about the production. The net result for the month has been a decrease in the visible supply of about six to seven million pounds. Unless the domestic manufacturers shortly receive new and large orders for finished goods, the metal cannot be expected to advance, and, considering the general industrial unsettlement, it is difficult to become enthusiastic about the immediate future. At the same time, it should be kept in mind that the world's visible supply is not a large one should the industrial situation improve and it is believed by many conservative people in the trade that same is bound to occur before the summer is over.

*President of the New York Metal Selling Company.

EDITORIAL

THROUGH train service has been re-established on the San Pedro, Los Angeles & Salt Lake railroad, the line having been re-built where washed out some months ago.

ARIZONA and New Mexico, it now seems, must wait still another session of Congress before being granted Statehood. It is a constant marvel what variety and abundance of reasons our Washington statesmen find for not doing something against which no good reason at all is urged.

RUMORS to the effect that Mr. John B. Farish would retire from consulting practice have been current. We are authorized to specifically deny the rumor and to announce, as we are glad to, that Mr. Farish hopes to continue his professional work as long as he lives and to have his son, Mr. George Farish, succeed him.

ONE of the most delightful exchanges which comes to our desk is the *Congressional Record*. It is as inconsequent as a dictionary and nearly as comprehensive. We go through it with perennial interest and occasionally find something worth while. This week we have abstracted some data on underground mine refuge chambers, a really important subject. In connection with the article the description on another page of the successful drilling of holes as much as thirty inches in diameter may be read with especial interest.

PENSIONS for workmen will undoubtedly become more common in this country as time goes on. Recognition of faithful service must be made. The intelligence and ambition of the workmen necessitate it. Direct profit-sharing has not proved successful, the most advantageous form, perhaps, being that of opening to workmen the opportunity to acquire stock in the enterprise with which they are identified, at fixed and reasonable prices. This has been done by Phelps, Dodge & Company, Inc., by the United States Steel Corporation, and others. Several years ago Mr. Andrew Carnegie placed in trust the sum of $4,000,000, the income from which was to be applied to the payment of pensions to employees of the Steel Corporation, and the plan has resulted so successfully that the Corporation has added $8,000,000 to the fund. It is eminently fit to make such provision for the needs of loyal workmen, but the distribution of such moneys is in some degree a gratuity. It is not based upon any co-operative principle other than that involved in the physical association of master and man. Encouragement to provide against times of stress by investment in an insurance policy makes

appeal to better instincts, and ennobles the relation of employee to employer, rather than to make the future benefits depend on mere adherence to a job.

REVISION of the mining law is everywhere admitted to be needed. The American Mining Congress at its last session appointed a committee to urge upon Congress at Washington the necessity for a thorough revision and the desirability of mining men being consulted in making changes. What is needed is a Congressional investigation as to the operation of the present laws and the character of changes needed. Public hearings should be held in Washington and at various Western cities so that the fullest information may be available. We understand that Mr. E. B. Kirby and the committee have in mind some such procedure, and they should be supported in urging it. Radical changes are needed in many directions, but uninformed action may do much damage. Public hearings tend to crystallize public opinion and facilitate correct action.

APPROPRIATIONS for the Geological Survey and the Bureau of Mines have been fixed in the Sundry Civil bill which has passed both House and Senate at Washington, and is now in conference. In connection with the Geological Survey the prineipal change is a gratifying increase from $225,000 to $300,000 in the amount appropriated for geologic work proper. Appropriations heretofore made to the Survey for technologic work are, in the main, transferred to the Bureau of Mines. As the bill passed the House the sum set aside for the Bureau included: for general expenses, $54,000; for moving offices and laboratories, $14,600; for rent and stationery, $10,000; for investigation of mine accidents, methods of mining, treatment of ores, and other technologic investigations pertinent to the mining industry, $310,000; for analyzing and testing fuels, $100,000; for preparation of reports, $5000; for salaries of the Territorial mine inspectors, the inspectors being authorized to inspect coal and other mines in the District of Alaska to which District the provisions of the Act of March 3, 1891, are extended and made applicable, $4000; for expenses of inspectors, $4500. The House refused to appropriate for continuing the investigation of structural materials begun under the Geological Survey and transferred to the Bureau of Mines when the latter was formed, and appropriated instead $50,000 for this purpose to the Bureau of Standards. The Senate reinserted the current item of $100,000 for this work under the Bureau of Mines, and the matter went to conference with results not announced at the time of this writing. While there is room for some difference of opinion as to which Bureau should have charge of much of the work, there is no room for doubt that it was taken from the Bureau of Mines in the House by sharp practice. However this matter may be settled, the new Bureau will begin work with appropriations adequate for a large amount of useful work. It is understood that the increase in the principal appropriation to the Bureau of Mines from $250,000 to $310,000, made on the floor of the House, was to provide for additional mine rescue stations.

Romancing About Mining

It is almost cruel to criticise, it is so easy. The cruelty and the ease of it are even greater when the mark is a literary gentleman employing his artistic temperament in the floating of mines esthetically. Mr. Julian Hawthorne is an artist! The significance of the term depends upon the tone of voice, as anyone may see by trying. We have no objection to literature; we read Professor James' guesses on the accidental in nature, and Goldwin Smith's views on history. But really and truly this romance which we have just read is the most astounding! The worthy customs officer of Salem, even when he filled 'The House of Seven Gables' with gruesome mystery, never dreamed such dreams as have been inspired in his son Julian by the lure of Mr. Eze Mark's pocket. "An artesian well to the earth's centre would be the ideal gold and silver mine. Up would rush the long imprisoned genii of wealth with a roar heard in the moon" (we like that simile; it is impressive, almost magnificent), "and would spread in stupendous floods over the surface—a flood hundreds of miles thick, and thousands in area" (as for the latter we refrain from giving Mr. Hawthorne the scientific reasons why it's all bosh and nonsense). It may be said in passing that Mr. Hawthorne is a confirmed baryspherist. He probably doesn't know it; nevertheless we are ready to vouch for the truth of it. He believes that the heavy metals sank by gravity to the centre of the earth; that dear old Mother Earth therefore has a golden heart. Here is another reason for the worship of Demeter, and perhaps some mythologist may connect it with the Eleusinian mysteries. That 'golden heart' might entice Mr. Hawthorne, but either respect for dame Demeter or recollection of the misfortune of the person who killed the goose that laid the golden egg, Mr. Hawthorne gives wise admonition; "but let us not dig that well," he says. No, Mr. Romancer, we will not! We are willing to dig deep for gold, but that would be too deep; we think there is a good deal of anathema hurled by the Articles of Faith against works of supererogation. The romance in which we find all this is a pamphlet entitled 'Julian Hawthorne & Company'; it concerns the known and the unknown in the universe at large, on the earth in general, and at Cobalt, Ontario, in particular, at which point real silver has for some years been produced by plain men on a very profitable basis. We believe that mining on a large scale will continue at Cobalt for a long time to come: what fate will befall Mr. Hawthorne & Company is expressed in the ever-ready Mexican phrase *quien sabe.*

The Ohio Mines Company has also entered the literary arena. The production of this corporation is a history called 'The Gold Book'. It is worked out á la Kniekerbocker, starting with the dawn of time and the eradle of the race. We read of Cadmus, 1594 B.C.; of Jason and his Argonauts: we follow Hannibal, and Caesar, and sail westward with Columbus and—so on. We sweep the earth: we hear the roll-call of the mining barons. "Hearst Estate," "here, with forty millions"; "James G. Fair Estate," "there with twenty-five millions," all the

way down through the Crockers and Haggins and Mackays and Floods to poor little Robert C. Johnson with only $5,000,000! Having reviewed the history of the world in relation to gold, we are at last inducted into the presence of the arch-venerable "Yavapai the Wonderful," which for the benefit of gentlemen in the Transvaal we will say is in the quite remarkable territory of Arizona. The Ohio Mines Company has issued in addition a report by Mr. W. A. Warwick which seems sound, sane, and conservative. It is an easy calculation for a prospective investor to estimate the value of shares in the company on the basis of Mr. Warwick's report. This is well and good. We wish it stood alone. The thing we object to is coupling with it matter which will give the reader the gold fever, so that he will deliver over his money while still suffering from the attack.

Mr. Ballinger and the Cunningham Claims

The Pinchot-Ballinger investigating committee, it is now announced, is not likely to present a report to this session of Congress. While not wishing to discuss the matter in detail in advance of the presentation of the report, we have reproduced on another page a summary of certain phases of the case, printed originally in the *Nation*. In this connection it seems worth while to point out a few things concerning which there is much misapprehension.

It has been quite generally assumed that the Cunningham claims were tinctured with fraud and that any disposition on the part of the Secretary to forward their patenting was to be condemned. We do not believe this assumption is warranted. Mr. Horace V. Winchell, concerning whose knowledge and integrity there can be no question, has presented the evidence so fully and so fairly as to leave little doubt that these famous claims were located and carried forward toward patent in strict conformity to the then existing law. The latter, it is admitted, was a poor law and was properly changed at a later date; but that cannot affect rights accruing under it while it was on the statute books. It was proper enough, so long as any question remained, for Mr. Garfield and other officers of the land office to insist that the claims be put to proof. The fact that receivers' certificates had been issued did not close the matter, and Judge Curtis H. Lindley so advised the Guggenheims when they were considering the purchase of the claims. The resultant necessity for the claimants to defend their title is a hardship on them, but may become incident to acquiring any piece of public land. In the face of the repeated charges made by agents of the Department, it was entirely proper that the matter should be fully investigated. It is equally proper, however, that if the rights of the claimants prove well founded, they be respected and the patents be issued to them. The matter is still under review and has been needlessly drawn out and complicated by popular clamor founded on misunderstanding of the facts. The claims are likely to be allowed, and it will be done, we believe, on the basis of the law and evidence and not because of any improper desire to favor any individual or corporation at the expense of the public. Furthermore, while we yield to none in our interest in conservation, we believe that it is in accord with sound public policy that the block of ground represented by the Cunningham claims pass into private ownership and be permitted to be developed. The value of the claims, as we have already shown, has been grossly exaggerated. For the founding of a new enterprise under such difficulties as must be met in Alaska, 5000 acres of coal land is none too large. If the claims be allowed and ultimately pass under the control of the Copper River railroad, the amount of coal involved will not be disproportionate, nor will it give the owners a monopoly of the market. It is also to be remembered that the price paid for the land, with that spent in surveys and in perfecting title, is not low or out of ratio to lands containing an equal amount of coal in the States. The public has apparently made up its mind to the effect that Mr. Ballinger should resign, and with that conclusion we have no quarrel. We protest, however, that in this one particular, public opinion is based upon false assumptions and misunderstandings.

BY THE WAY

The Pinchot-Ballinger investigation has been completed. There is much difference of opinion as to the conclusions properly to be drawn from the evidence, and the following summary published in the *Nation* will be read with interest.

The long-protracted hearing in the Ballinger investigation came to an end last week with the oral argument of the attorneys. On neither side was an attempt made to cover with convincing precision all the points in dispute. This indeed was impossible in the limited time at the disposal of counsel, as would be shown by the attempt of any impartial student to settle a single one of these questions. Not until the briefs have been submitted, and the evidence studied in the light that they should furnish, will a trustworthy conclusion on the whole case be possible. Nevertheless, the survey of the case afforded by the oral arguments makes the present an appropriate time for weighing the general controversy.

In the first place, there are some points about the nature and genesis of the case of which the public needs to be reminded. Especially as regards Mr. Glavis, it is necessary to recall to mind the character of his initial connection with the matters involved. Whatever basis there may be, or may be alleged to be, for supposing that the animating force behind the developments for the past ten or twelve months is of a political or personal nature, no such allegation can be made as to Mr. Glavis' first resolute interposition in the Alaskan coal claims. No Rooseveltian plot can have been at the bottom of his zealous interference in the year 1907, to prevent the patenting of the Cunningham and other claims without searching inquiry. Mr. Ballinger was at that time Commissioner of the General Land Office; but Mr. Garfield was Secretary of the Interior, and Mr. Roosevelt was President. An intense desire to preserve for the nation valuable lands to which the private claimants were not in his judgment lawfully entitled is the only motive which could at that time have actuated Mr. Glavis. Not only was there no possibility of a politi-

cal motive, but personal animus was equally out of the question. His efforts were made within the Land Office, and they were successful. There arose at that time no complaint or scandal. It is not impossible that Mr. Glavis was over-zealous or that his judgment was at fault; but the fact is that for two years, unremittingly, he stuck to this line, no matter who was Land Commissioner, or Secretary of the Interior, or President. Eventually, he had recourse to the Attorney-General, Mr. Wickersham, and finally to the President. Mr. Taft called upon Mr. Ballinger and others for replies; and, having examined these replies, he exonerated Mr. Ballinger and his subordinates and authorized the discharge of Mr. Glavis. Only after his discharge, and more than two years after the beginning of his activity, did Mr. Glavis enter into a public agitation of the case through *Collier's*.

A second point, which should be clearly apprehended, is that the question before the committee, the President, and the people, all along, has not concerned corrupt conduct on the part of Mr. Ballinger. The question is and always has been, whether he has fulfilled the peculiar responsibilities of his office with single-minded fidelity to the rights and interests of the Nation. To show that those interests have not been in safe hands, it is not necessary to convict him of a pre-conceived purpose to betray them, or to prove the existence of any corrupt motive. If, in point of fact, he has been eager to facilitate the patenting of doubtful claims; if, in point of fact, he has been conspicuously wanting in zeal for the protection of the Nation's rights—the charge made by his opponents is established. The accusations against him under this head relate on the one hand to his attitude toward the Forestry Service and the Reclamation Service, and, on the other, to his conduct concerning the Alaskan coal lands, especially the Cunningham claims. The question of fact and law involved are anything but simple; but as regards the coal lands, some indication of the situation may be given.

It is agreed on all hands that the existing law on the subject of Alaskan coal lands is utterly unadapted to the situation concerned. That law is designed to prevent the taking up of large tracts by private owners, the normal amount permissible being limited to 160 acres. But these lands cannot be worked profitably in small parcels; and everybody agrees that a radical change should be made in the law. Meanwhile, however, there are two opposite attitudes which may be adopted. One is, that so far as possible the land should remain the possession of the Nation until such time as legal provision shall be made whereby large holdings can be worked, with the people coming in for their full share of the benefit of such working; the other is, that inasmuch as the land cannot be worked in small parcels, the Government should look with leniency upon devices whereby, while superficially observing the law, private interests may contrive to get possession of large and extremely valuable tracts upon the easy terms designed for small holders. That there is a certain amount of sentiment in the Far West in favor of this latter view is probable; that it is the view taken and promoted by the capitalists interested in getting possession of the lands goes without saying. And what seems established with a fair approach to conclusiveness, in spite of the complexities and contradictions of the mass of evidence, is that Mr. Ballinger's acts were largely influenced by this view of the case, and that, but for the dogged opposition of Mr. Glavis, this view would have prevailed long ago in the Cunningham claims. To substantiate this assertion it would be necessary to adduce a number of special circumstances, all pointing in that direction, which have been brought out in the evidence. There is hardly one of them for which some explanation has not been offered, and to examine the pros and cons thus presented is here out of the question. It is only by considering them in conjunction, and getting their net result after all criticisms and explanations have been allowed for, that one can estimate their true significance. For this reason, it is so regrettable from the standpoint of Mr. Ballinger that the extraordinary series of inaccuracies and concealments took place which was the centre of public attention two weeks ago. In consequence of these developments, the President's letter of exoneration and the Attorney-General's summary and opinion have been largely deprived of the weight that would naturally attach to them. In default of a reading of the evidence—an impossible task to all but one person in a hundred thousand—it is upon the judgment of such referees that people naturally rely. That both the President and the Attorney-General were themselves fully assured of the justice of their conclusions, we entertain not the slightest doubt; but it is by no means so certain that in arriving at these conclusions that they were not unduly guided by ex-parte information and assistance.

No survey of the case, however broad and general, can omit a reference to Mr. Ballinger's conduct on the witness-stand. In several instances, when questioned by Mr. Brandeis concerning extremely simple matters of fact, he made a pitiable exhibition of shiftiness, evasion, and—to call things by their right name—untruthfulness. To deny a thing and almost in the next breath to admit it when denial was plainly useless; to say he knew nothing about the matter, and, after a little prodding, to show that he remembered it quite accurately; to present the appearance of one willing to lie, and yet afraid to stick—this is a showing not only lamentable in itself, but doubly significant in regard to the trustworthiness of his statements in general; and it is significant as bearing on the question of his fitness for the custodianship of the great national interests of which the Secretary of the Interior is the trustee. We would not magnify the circumstance; we would not say that Mr. Ballinger's character is to be measured by these manifestations. Some men, not particularly dishonest, thus instinctively grasp at straws when placed in an uncomfortable position; and we would not say that more than this is true of Mr. Ballinger. But it is not to the keeping of such men that we entrust great national possessions for the seizure of which shrewd and unscrupulous and powerful private interests are constantly on the alert; nor is it to the statements of such men that we give the benefit of every possible doubt when confronted with opposing evidence.

Los Pilares Mine, Nacozari, Mexico

By Courtenay De Kalb

A geological problem of extreme interest is presented by the splendid mine which has made the Moctezuma Copper Co. one of the great enterprises of Mexico. The property belongs to Phelps, Dodge & Co., and is situated near Naeozari, in Sonora, Mexieo, 75 miles south of Douglas, Arizona. Opinions are not in aeeord eoncerning the genesis of the Los Pilares orebody. Undoubtedly it is eomplex. No simple theory may aeeount for it. In fact the development done at the present time, despite the enormous extent of the workings, is insufficient to demonstrate the order and eharaeter of the geologie events that here oeeurred.

The orebody is a zone or belt surrounding a central core, elliptical in horizontal eross-seetion, measuring approximately 2000 ft. on the major axis by 800 on the minor. This form was suspected but not proved when S. F. Emmons made his investigation of the deposit in 1905. His observations were remarkable for their comprehensiveness, considering the brief period of time in which he had opportunity to study the mine. As a point of departure it may be well to recapitulate his eonelusions. He showed that there had been an epoch of dynamie movement producing fault planes, shattering the mass of Pilares mountain, aeeompanied or followed by the introduetion of silica and metallic sulphides, cementing the shattered fragments into a breeeia. Eruptive action followed, during which time diabase dikes were introdueed, and these were sueeeeded by a dynamie movement opening new eracks through whieh surface waters eould enter. Mr. Emmons distinetly sets aside the probability of the existenee here of a voleanie stock around the periphery of whieh mineralization oeeurred. The contrary has not yet been proved, but the general appearance today strongly favors sueh a eoneeption. The mass of rock which was at once the loeus and mineralizer for the orebody is probably rhyolite. Mr. Emmons tentatively elassified it as a quartz monzonite, but he also called attention to the possibility of its being a highly altered and silicified variety of andesite. The rock is certainly interlaeed by minute veinlets of secondary quartz, as well as being impregnated by grains of the same mineral. The stoek-like character of the mass is now strikingly apparent, but the warning of Mr. Emmons that "eirenlar orebodies, or so-ealled ehimneys, often result from the mineralization of a shattered area, enelosed by three or four intersecting fault-planes," must be borne in mind until more detailed study of this oeenrrenee can be made. It is unquestionably a ehimney-like mass, impregnated with sulphides of iron and copper, enriched around the elliptieal periphery. The interior rock-mass contains pyrite and ehalcopyrite, disseminated after the manner of the sulphides in the monzonite porphyry deposit at Ely, Nevada. The entire core of silieious rock at Los Pilares will average, so far as present workings reveal its eharaeter, as much as 1% eopper. This brings it within the eategory of the disseminated porphyry deposits. It is not now looked upon as a souree of eommereial ore, however, only the enriehed surrounding zone, like a eireular vein, whieh yields about 3% eopper, being taken out for eoneentration. This body of impregnated rhyolite porphyry spreads out upon the surfaee in the form of a eap. The limits have been well determined in one direetion, though they remain uncertain on the opposite side. Where definite observations are possible the porphyry is seen to overlie the original andesite of the country. The eap has been deeply eroded at places, but on reeonstrueting its shape it appears like a mushroom, with the mineralized stoek for its stem. The eap is partly overlain by andesite breeeia. It may have been a laeeolith, now largely exposed by denudation.

Nacozari, Mexico.

The present eommereial ore in portions of the mine is sharply bounded by slip-planes, on the outer rim as pointed out by Mr. Emmons. This is not universally the ease, however, on the inner boundary, the orebody quite as often possessing no limits recognizable to the eye, but gradually shades from commereial to non-eommereial ore. Breeeiation is persistent in the deeper levels as well as near the surfaee. Bornite and other secondary copper minerals were abundant in the upper part of the mine. These have practieally disappeared below the 700-ft. level. The ore has become a dense fine-grained pyrite with ehaleopyrite replaeing the porphyry. The average composition of the present output of the mine is approximately:

	Per cent.
Copper	3.00
Alumina	12.52
Silica	50.24
Iron (metallic)	14.18
Sulphur	11.04
Lime (CaO)	0.47

It is interesting to observe that despite the seeondary enriehment nearer the surfaee, the ore in depth, which is regarded as primary, shows no appreciable diminution in eopper content. It is not certain, however, that the elliptieal enriehed zone

does not represent a concentration from the core of porphyry toward its outer edge, although the tendency to the formation of shoots of greater width and of irregular shape indicates the existence of channels which may have served for the rise of solutions from below. The orebody in places is as much as 300 ft. wide, while the more usual width is from 50 to 150. The northwest end is the most irregular as it is also the widest portion of the mine. The alteration has been excessive at this point, and there is here an excess of water in the orebody.

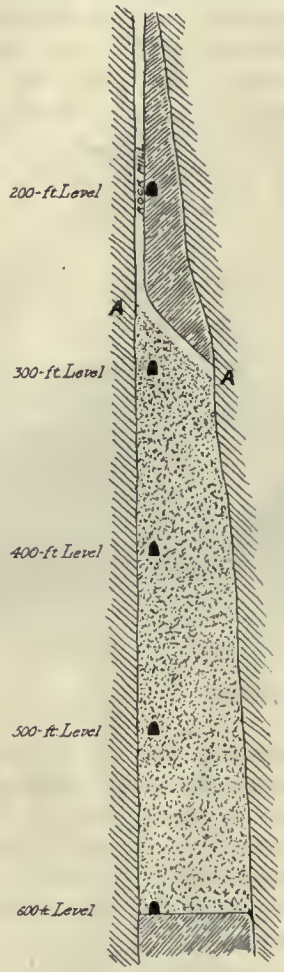

Fig. 1.

The mining methods are of great interest. No attempt has been made to cave, and in only a few situations has square-setting been adopted. Less than 10% of the workings is held open by square sets. The system is first of all that known in New Zealand as 'shrinkage' stoping, that is, allowing the stope to remain filled with broken ore, only the excess bulk produced by breaking being drawn off and sent to the mill. After a suitable amount of ground has been thus removed from 100 to 300 ft. high according to local conditions, the broken ore is all drawn and if ore still remains in that back, or other conditions require it, its space is filled with broken waste milled down from the surface. The same system, however, is not employed throughout the mine, conditions necessitating various modifications. On the northeast or 'caliche' side, a stope on the 200-ft. level, 600 ft. long by 15 to 30 ft. wide, is being carried by the shrinkage system to the capping. It will be drawn empty and the capping and walls shot down to fill it. From the 600-ft. where the orebody ranges from 100 to 300 ft. wide, upward to the 200-ft. level, where the orebody ranges from 300 to 100 ft. wide, stopes 50 ft. wide are being carried across the strike of the deposit, leaving 50-ft. pillars between. Filling is done progressively as the stope advances so that consolidation will have occurred in the 'fill' by the time the 200-ft. level is reached, when the pillars will be removed by top-slicing. The decomposed country rock makes an admirable fill-

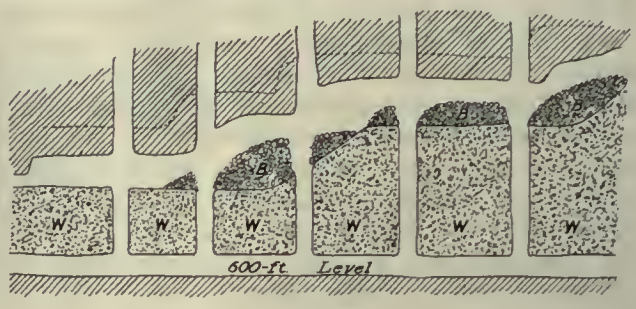

Fig 2.

ing, and consolidates so rapidly as to make a hard smooth floor in the stopes at once. The ore can be shoveled as readily from this newly made 'fill' floor as from boards.

In Fig. 1 is shown the method, now in progress on the southwest or 'Evans' side of the mine, in vertical section. The stopes from the 600-ft. level are carried up by successive cuts and fills. The waste is sent down rock-mills from the levels above. When the 300-ft. level is reached the surface of the fill will be left inclined, as shown at AA. Upon this the ore above is broken, and the stope is carried upward to the capping by the shrinkage system, the excess bulk being drawn from the foot of the stope

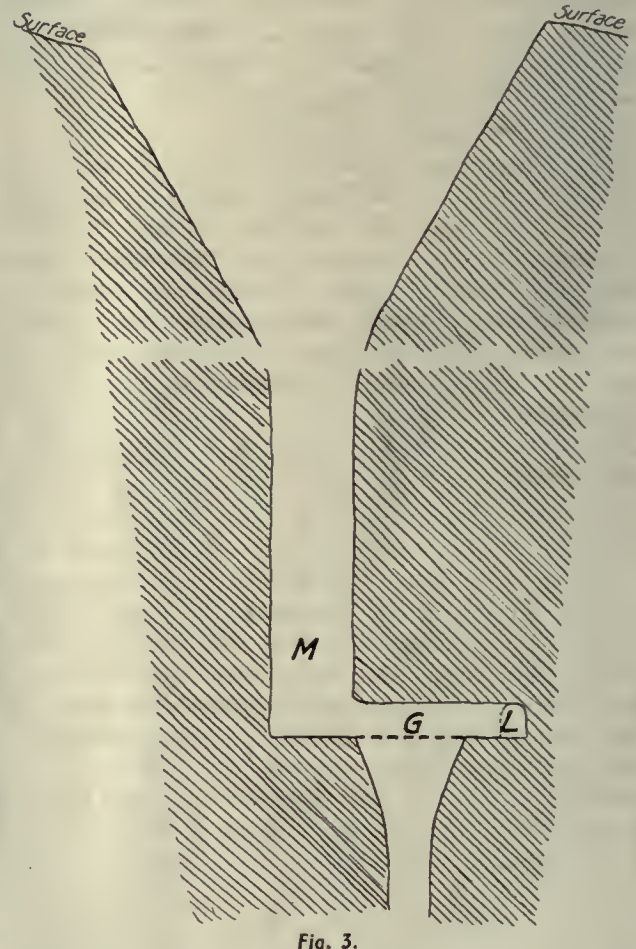

Fig. 3.

through suitable drifts and cross-cuts. Two or three pillars are left in the lower stopes to insure stability of the walls. These will not be recovered until the ground is worked to the surface. Then they will be removed by top-slicing. It will be seen that this is the direct opposite of the method used in the wider stopes where the upper levels are worked out before the stopes reach the 200-ft. level, after which the pillars are won by top-slicing. The method of working a 'cut and fill' stope is illustrated in the longitudinal section, Fig. 2. This shows the operation as now being conducted from the 600-ft. level on the southwest side of the mine. Mill-holes are first driven 50 ft. apart. These serve for delivery of the barren rock for filling the stopes, and also for cutting points. The ore is cut in stepped slices, following the usual overhand-stoping system, the men standing on broken ore, BB, as the cut advances, and the broken ore in turn resting on the rock-fill W, W, W, below. The stope shown has a length of 350 ft., with a maximum width of 75. In the beginning the length of these open stopes was limited to 150 ft., with 50-ft. pillars between, but as experience of the strength of the ore was gained the length was increased, until today no fear is entertained in leaving long stretches unsupported. The span of 75 ft. in places has proved perfectly safe, but in some stopes the conchoidal slips, evidently due to pressure resulting from expansion of volume during alteration, present enough danger to necessitate narrower arches. In a portion of the ground these slips are very numerous. It is here that square-setting is practised.

Large Open Stope, Los Pilares Mine, Nacozari, Mexico.

The fill-holes, as seen, lead directly into the stopes, but they do not extend to the surface from the stopes below the 200-ft. level. The main rock-mills for delivery of rock to lower levels terminate in bins from which the material is drawn into 20 cu. ft. cars, trains of seven being made up and drawn by 3-ton Goodwin electric locomotives to the mill-holes leading into the stopes. These holes are spaced 50 ft. apart, on the southwest side of the mine, following the strike of the deposit, and on the northeast side, where the orebody is wide, they are similarly spaced transversely, or across the deposit. The rock for filling is broken by deep shots around funnel-shaped quarries at the surface, terminating downward in large mill-holes 15 by 15 ft. in section. In these mill-holes are off-sets, as shown, each provided with a grill of iron-faced timbers spaced 18 in. apart. The rock banks at the off-set, partly covering the grill. Here workmen can break the larger masses to suitable size, without being exposed to danger. The total cost of rock-fill delivered into the lower stopes and spread with an even top ready for continuance of mining, does not exceed 25c. per ton.

On the 400-ft. level where the orebody is narrow, and the shrinkage system is used, drifts 5 by 7 ft. are driven in the country rock at a distance of about 10 ft. from the vein. Cross-cuts 5 ft. wide are then driven, 15 ft. centre to centre, through which the excess bulk of ore is removed by shoveling. The walls at other places are so sound that stopes of enormous dimensions are opened, some of these being 250 ft. in height by 110 ft. in width, which stand without any filling. In stoping, both Waugh and Shaw drills are employed. One-inch cross-steel is employed, with bits expanded to 1¼ and 2¼ in. The dynamite used is 40%, and the sticks are 1⅛ in. diam. These drills average a duty of 50 ft. of hole per diem, and the normal output per machine is 40 tons of ore. The length of holes drilled is from 6 to 7 ft. The cost of mining, while not definitely stated, is low, propably less than $1.50 per ton. Even where square sets are used the cost does not ascend to $2.50 per ton. The mill-holes are unlined, but the

ore-chutes are lined with 2-in. plank. The manways are timbered with boards 2 by 12 in. diam., fitted with bevel-joints at the corners. This insures stability and safety.

The ore is assembled and dumped into chutes leading to main loading bins on the 700-ft. level. A principal gangway, or adit, traverses the central porphyry core from the portal on the northwest side of the mine, extending about S. 35° E. 5000 ft. to the main shaft, cross-cutting the elliptical orebody along its major axis. In this adit is a 36-in. gauge track, over which the ore is hauled to the portal in 25-ton steel side-dump cars, made by the Ingoldsby-Dusey Car Co., in trains of seven, by 6-ton General Electric Co.'s locomotives. The power is transmitted from the central power-station at Naeozari. The cars are then delivered to the steam-locomotives which take them to the mill down a greatly detoured railroad six miles long. Timbers and other mine-supplies are taken by the trolley to shafts at the points of intersection of the aforementioned adit with the vein. Timber-framing, drill-sharpening, and general machine-work are all done on the surface near the shafts. Drills are sharpened by a Leyner machine, which is operated by Mexicans and Japanese. No American labor is employed aside from shift-bosses and timbermen. The Mexicans have been trained to all classes of work, which is done in accordance with the best methods used in the United States. The direct supervision of the mine is under Charles A. Smith, assistant superintendent.

Salt fields are very extensive in western Ontario. The salt beds form part of the Onondaga formation of the Silurian age, and the saltiferous horizons underlie a territory extending from Kincardine to Lake Erie, bordering Lake Huron and the Detroit river. The basin measures an extreme length of 150 miles, with a maximum width of 40 miles at the centre tapering toward the end. This would cover an area of 2500 square miles. An idea of the immense deposits of salt contained in this area may be gathered from the fact that a bore-hole sunk at Goderich, in Huron county, to a depth of 1517 ft., went through six beds of salt ranging in thickness from 6 to 36 ft.; whereas at Windsor, in a well 1672 ft. deep, four beds were traversed, one of which is said to measure 250 ft. in thickness.

Government foresters are inspecting the proposed route of the Humboldt & Eastern railroad, and it is believed that some definite action will be taken shortly to have active construction work started on the line. As proposed the road will extend eastward from Humboldt bay for 175 miles to the upper Sacramento valley. Seventy miles of the line will extend through the Trinity national forest reserve in Trinity, Humboldt, and Shasta counties.

The Geological Survey of Canada will have nearly a dozen parties in the field in British Columbia this season and work will be done on the ore deposits of Atlin district, Portland Canal district, Hazelton district, Vancouver island, the Tulameen platinum deposits, West Fork of Kettle river, Sloean, Boundary, East Kootenay, and Ice River districts.

Refuge Chambers in Mines

Suggestions for equipping safety chambers in coal mines and connecting them with the surface by drill-holes have been frequent of late. While in metal mining there is not the same urgent necessity for them, there have been instances where such chambers might have resulted in the saving of lives and the subject is not without interest. The following plans and account were prepared for the Charleroi mines of the Pittsburg Plate Glass Co. by Jesse J. Johnson and presented by John K. Tenner in the course of a debate in the House of Representatives at Washington on mine rescue work.

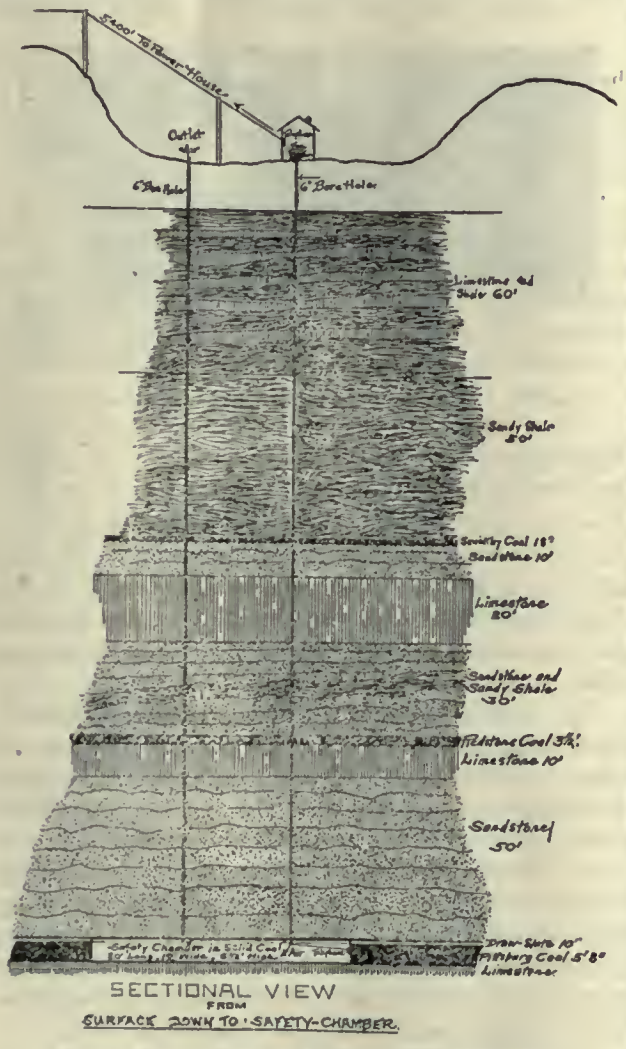
In a great many explosions the majority of those lost are killed outright; but in numerous cases, men have traveled long distances after the first shock of the explosion, only to meet death in their tracks by the after flow of gas. On actual tests of a bore-hole 6 in. diameter, having a depth of 300 ft. from surface to the coal, the readings show the velocity of the air passing up the bore-hole was 2000 ft. per minute. It is a matter of scientific interest that life was sustained in the Cherry mine, Illinois, one week after the mine fire started in an atmosphere in which there seems to have been upward of 5% of carbon dioxide and an atmosphere in which lamps would not burn. It is therefore reasonable to conclude that if several underground life-saving stations with bore-holes to the working veins had been previously installed at the Cherry mine, a number of the entombed miners could have reached these stations and a supply of fresh air and plenty of food could have been delivered from the surface.

One of the chief difficulties confronting the rescuers in mine disasters is the lack of information to know how and where to proceed into the parts of the mine where lives could be rescued. At the Courrieres, France, disaster, on March 10, 1906, the most fearful disaster which ever overtook any mine in any part of the world, where 1211 lives were lost, four hundred and forty three miners descended No. 3 pit, and of these only 13 or 17 escaped; 500 went down No. 2 pit, and of these 401 escaped; 852 went down No. 4 pit, and of these 175 escaped; making a total loss of 1211. The rescuers report that many lives might have been saved if they had only known in what direction to explore, and this is amply proved, as either 13 or 17 persons escaped alive from No. 3 pit at noon on the Sunday following the explosion, and later 13 more were rescued after 20 days' entombment in No. 2 pit. On further examination, evidence was found showing that hundreds of these men lived for days, some for weeks, living on bark from posts and putrid flesh.

At Cherry, Illinois, when on November 13, 1909, where about 300 lives were lost, similar conditions as at Courrieres prevailed. The 20 miners rescued one week after the mine fire started could have been rescued one or two days earlier had the rescuers known the situation of the miners and known in what direction to explore. On November 23, four rescuers reached the third vein. They found from 150 to 169 bodies, the count varying. Some of the men had made fans from drill machine parts, but no

barricades had been built. None of the notes indicated that the men had been conscious after Monday following the fire. This is conclusive evidence that a great many of the entombed miners lived 60 hours after the fire started.

At Primero, Colorado, February 2, 1910, 75 lives were lost. Eleven men retreated after the explosion to a room, where they remained a number of hours, but becoming impatient at delay in being rescued and in an effort to find good air started out into the entry and were suffocated by after damp, with the exception of one man named Virgen, who was rescued. The portion of the mine in which these 11 men worked was 1600 ft. from the nearest explosion and was absolutely unaffected by the explosion, and



Plan of Rescue Chamber at Charleroi, Pennsylvania.

in it the air remained good, due to the short circuiting of the after-damp currents around it. Had they been able to communicate with the outside and obtained instructions to stay in safety until reached all would have been saved.

The evidence gathered is conclusive that this subject is worthy of consideration and would certainly justify the expense in installing the underground life-saving stations to save the lives of miners who are not in the immediate zone of the explosion. The location of underground life-saving stations is a matter for every mine manager to decide for himself, and I can only suggest some ideas as to the size of the entrance and location of doors for isolating the air within a certain area surrounding the underground life-saving station. At distances each way from the entrance to the life-saving station suitable to conditions, I would erect two doors of boiler plate, built in recesses in the ribs of the entry, so that they will work flush with the sides of the coal; would also erect one door at the entrance to the safety chamber from the entry, and another one at the place where the chamber is widened from the entrance entry. The chamber should only be 12 ft. in width and not over 80 ft. in length, and all walls should be whitewashed. It should be equipped with a telephone connected through the bore-hole with weatherproof cable to reach the surface, thence by telephone line to surface plant. It should be equipped with a large roll of brattice cloth, a medicinal box of first-aid appliances, safety lamps, and a number of oxygen flasks. The sides and roof of the chambers should be lined with concrete, and should be connected by two 6 or 8-in. bore-holes with the surface. One bore-hole could be used for inlet air to be driven by a small fan and the other bore-hole for the outlet air. Water and food could be delivered from the surface by means of the bore-holes.

Another suggestion has been offered, which is to use a 2-in. pipe inside of the 6 or 8 in. By compressing to 80 lb. 100 cu. ft. of free air per minute could be sent through a thousand feet of pipe with a loss of only 5.8 lb. in pressure. Judging from the rescue apparatus, it takes an average of 10 litres of fresh air per minute for each man. This is about one-third of a cubic foot; so with 100 cu. ft. of air you could have sufficient air to sustain 300 men.

Long-span concrete bridges are receiving attention so extensively that there can be no question about the firm position this type of structure now holds in engineering practice. In this country there has recently been completed the 233-ft. Walnut Lane span in Philadelphia, and the Rocky River bridge of 280-ft. clear span is now under construction at Cleveland. A bridge having a central span of 281 ft. has been designed by the city engineer of Spokane to carry Monroe street across the Spokane river. A span of 285 ft. has been adopted to carry the New York barge canal over a gorge in the vicinity of Medina, New York. The 710-ft. span of the proposed Henry Hudson Memorial bridge at New York has been the subject of so much discussion that it is at once recalled when the design of long-span concrete structures is mentioned. This bridge, however, is apparently not likely to be constructed for some time, owing to the action of the city authorities in withholding further appropriations for the engineering work. With the exception of the Henry Hudson bridge, the longest span yet proposed is that of a bridge recently placed under contract by the civic authorities of Rome. This will cross the Tiber with a span of 328 ft., having a rise of 1:10 and carrying a roadway 65.6 ft. wide. The cost of this bridge has been estimated at £50,000. A bridge comparable with it in every respect is now more than half finished at Auckland, New Zealand. It has a total length of 910 ft., and its main feature is a span of 320 ft., which will carry a 40-ft. roadway at an elevation of 174 ft. above the ground.

Reclaiming Flooded Drift Mines in Alaska

By W. H. Lanagan

During the summer of 1909 and the winter of 1909-10, three different methods have been put into practice to reclaim flooded drift mines in the Nome district, Alaska, the object being the freezing of a bulkhead in a drift in order to shut off the flow of water from wet ground that had been inadvertently tapped while drifting in adjacent dry frozen ground. On the Bessie Bench, famous as one of the greatest producers of the Third Beach, one drift was successfully frozen off during the summer of 1909 by means

Fig. 1. Front View of Drill.

of an ammonia vapor refrigerating plant. On the same claim another drift was frozen off in February 1910 by means of a circulating solution of calcium chloride, cooled by a system of pipes in the open air. On No. 1 Below Discovery on Dry creek, two bulkheads were frozen in drifts by the use of cold air alone. The work was done during the middle of the winter.

In each case the flooding occurred in workings that were being carried on in what is called the 'slough-over' pay-streak, which parallels the Third Beach throughout, at a distance of 100 to 300 ft. south of it. This pay-streak appears to have had its origin in the concentration that took place on the sea-floor just beyond the belt scoured by the surf, and wherever the Third Beach was rich, the 'slough-over' has yielded a good profit. An exactly similar formation can be seen in the bar that parallels the present beach-line, at a distance of 100 yd. to the south.

A large portion of the Third Beach on the Bessie claim was frozen, but on the west end the work was carried into the thawed ground on the left limit of Saturday creek, and a heavy flow of water had to be pumped during the latter part of the work. The depth to bedrock was 120 ft., and after the pumps were pulled the water filled the old works and rose to a height of 60 ft. from bedrock. As a rule there is a belt of very low-grade beach and sea-bottom material between the Third Beach and the 'slough-over' pay-streak, but on the Bessie there is gold in paying quantities distributed over the old sea-bottom for a distance of several hundred feet to the south of the Third Beach. The value of the ground is not high enough, however, to warrant the heavy expense of pumping, and so care has always been taken to leave a safe pillar of frozen ground between the work and the old flooded stopes. In only a few cases have maps been kept that showed accurately the outlines of the old works that had to be avoided; drilling from the surface has often been resorted to for the purpose of establishing the outlines of flooded ground. In some cases ground contiguous to flooded works has been safely taken out, without the aid of maps or drilling, by feeling the way ahead of each thaw with a small drill-hole ¾ in. diam. When water is struck, the drill-hole can be plugged and it soon freezes back; the stoping never approaches closer than within 5 or 6 ft. of the flooded ground. Where there has been no circulation of water in flooded works for several years, a coating of ice from 2 to 5 ft. thick is found along the walls. In approaching work of this kind it has sometimes been possible, by discarding the

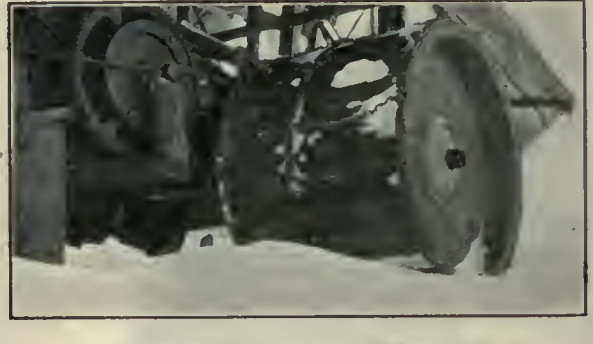


Fig. 2. Driving Gear and Drive Wheel of Drill.

steam-point when several feet from the old works, and breaking down the gravel with warm water from a hose, to remove all of the virgin ground right up to the ice-wall. Whatever method is used, the best practice is to remove the ground farthest from the flooded works first, so that in the event of flooding the amount of ground lost may be as small as possible.

The idea of tapping the flooded drift with drill-holes from the surface and using an ice-making machine to freeze a solid bulkhead and so to shut off the water and confine it to the old flooded works, came from John Brower. He, of course, obtained much information regarding the operation of refrigerating machinery from the companies operating cold-storage plants in Nome, but the details of the application of the process to the work in hand were worked out by him, and the success of the work is due to his originality and good judgment.

The flooded drift in which the bulkhead was to be frozen had been driven in frozen ground; after the drift was flooded the water raised in the shaft to a depth of 60 ft. and remained at that point. There was no circulation of water in the drift, and the presence of stagnant water would not draw the frost from the walls and floor, but would form a coating of ice. Consequently only the water had to be frozen, together with what material had sloughed from the walls and roof of the drift before and during the flooding.

The depth of the ground in which the drilling was done is 120 ft. The drill used was a unique affair designed two years ago by Mr. Brower to meet the peculiar conditions of the Nome tundra. A view of the front or drilling end is shown in Fig. 1. The principle of the ordinary power churn-drill is used,

but the power is furnished by a 10-hp. gasoline engine; the traction wheels are 6 ft. diam. and about 6 ft. wide, lagged with 2 by 6-in. planking. Moving over the thawed swampy tundra in the summer is greatly facilitated by the large wheels. A steel cable replaces the ordinary manila drilling cable. The bit is 5 in., drawn out to cut a 6-in. hole. The drill-stem consists of two stems joined together, and has a length of about 35 ft. No casing is used in frozen ground, and a drilling speed of 50 to 60 ft. per 10-hour day is not uncommon. The driving gear is shown in Fig. 2.

The width of the drift to be frozen was about 5 ft. Two lines of three holes each were drilled in the drift; each was carried into the bedrock for a distance of 2 or 3 ft. below the bottom of the drift; the distance between lines was 2 ft. and between holes 1½. A string of 1-in. pipe extending from the surface to the bottom and return, was placed in each hole. An ammonia-vapor refrigerating plant of 6 tons capacity, that is, with a refrigerating effect equivalent to the melting of 6 tons of ice in 24 hours, was used. The compressor was driven by the 10-hp. gasoline engine on the drill; the condenser was supplied with surface-water probably not colder than 50°F. The action was that of the ordinary refrigerating machine; the ammonia-vapor was compressed and sent to the condenser, where it was cooled to a liquid; it was then released by means of expansion valves into the pipes set in the drill-holes, whereupon it abstracted from the water in the drifts most of the heat necessary for its conversion into ammonia-vapor and the subsequent expansion of the vapor. The water about the pipes congealed into ice as its heat was withdrawn. The ammonia-vapor upon its return to the surface passed through the compressor and condenser, became liquid, and was again released into the pipes.

The machine was kept in continuous operation for 14 days. The fuel consumption under a 10-hp. load did not exceed 25 gal. of No. 1 distillate per 24 hours; the cost of this at 22c. per gallon amounted to $5.50, and the cost of two attendants, one on each shift, would bring the daily expense up to $18. On account of the freezing of the sloughed material in the drift it was not possible to reach the bulkhead itself after the freezing was finished and the water pumped from behind it, so the exact amount of freezing done is not known, but the bulkhead has safely withstood the pressure due to the 60-ft. head of water, for a period of several months. This piece of work was done by Mr. Brower under contract with the owners of the Bessie claim. The contract price is not definitely known, but it was much greater than the actual operating cost, since it had to cover the first cost of the refrigerating machine and the remainder of the equipment. The foregoing piece of work was done during the summer. The ammonia-process has the advantage over the two methods described hereafter, that neither of the latter can be used except during the winter.

No map showing the drift to be frozen in the second case was available, so it was necessary to search for the drift with the drill. The ground is 120 ft. deep, and 12 holes were put down at intervals of 6 to 8 ft. before the drift was found. Six holes were then drilled in the drift. Their relative position is shown in Fig. 3. The interval between holes is 18 to 24 in. It was found later that the holes in the drift had practically the same relative positions as on the surface 120 ft. above. The drilling was done without casing, as is the usual custom in frozen ground in the Nome district.

The arrangement of the freezing apparatus was as follows: A line of 1-in. pipe extending from the surface down into the bedrock, 2 or 3 ft. below the floor of the drift, was placed in each drill-hole; ordinary U returns were used at the bottom. On the surface a light trestle, 150 ft. long, supported 12 strings of 1-inch pipe, connected in pairs by returns at the far end. The surface pipes were connected in series with the drill-hole pipes, and a small circulating pump was added.

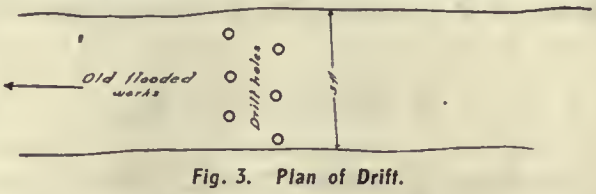

Fig. 3. Plan of Drift.

The circulating solution was one of calcium chloride; the proper strength was determined by testing in glass tubes until a solution was obtained that did not freeze when exposed to a temperature of 45°F. below zero. From the pump the solution passed through an air-cooled coil of pipe, and down the first drill-hole; upon its return it passed out through 300 ft. of surface pipe, and was cooled before entering the next drill-hole; and so on through the six holes and back to the pump.

The circulating pump was driven by a 2½-hp. gasoline engine. The circulation of the solution was continued for 14 days without interruption. The temperature during the period, which was in February 1910, ranged from a few degrees below zero to ten above. It is claimed that three or four days would have sufficed for the freezing had it been done in the latter part of January, when the temperature ranged from 20 to 40° below zero for several days.

At the expiration of the 14 days, pumping was started from the shaft south of the bulkhead, but freezing was not discontinued until six days later, as the fuel cost was only a few cents an hour, and very little attention was required. When the water was pumped out, the bulkhead was under a hydrostatic head of 60 ft. It was found when the drift had been cleaned out up to the bulkhead that a cylindrical column of ice with a radius of 18 in. to 2 ft. had formed about each pipe as a centre. The interlocking of these columns produced a solid mass of ice about 5 ft. thick. The pipes could be plainly seen through the clear ice. They will be recovered next summer by turning steam through them for a short time.

The cost of this work was considerable, owing to its experimental nature, the first cost of the equipment and the drilling necessary to find the drift. If the operation were repeated in a place where the position of the drift was known, the total drilling

necessary would not be more than eight holes, a total of about 1000 ft.; this could be done at a cost not greater than 60c. per foot, or $600 for the 1000 ft. The cost of setting up and operating the freezing plant, with a reasonable charge for the use of the equipment, would bring the total cost of the work up to $1000. This process can, of course, be used only during the winter, when the temperature is low enough for effective cooling.

On No. 1 Below Discovery on Dry creek (a claim near the Third Beach line, about one mile east of the Bessie), J. M. Crabtree and J. C. Murray tapped the

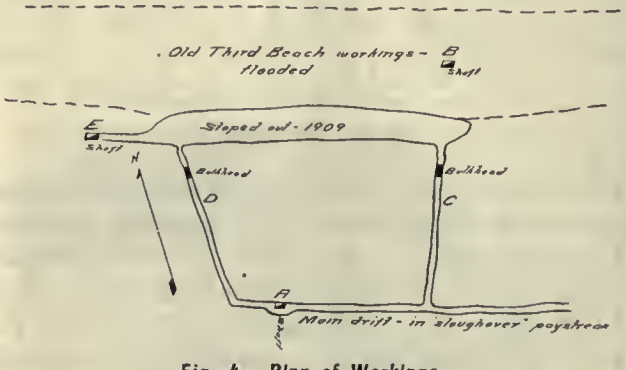

Fig. 4. Plan of Workings.

old flooded workings of the Third Beach while prospecting to the northward from their work on the 'slough-over' pay-streak. No maps of the old works were available, and inaccurate reports of the southward extension of the old work led to the flooding of Crabtree & Murray's mine when they thought themselves protected by 20 ft. of solid ground. Fig. 4 shows the general arrangement of the work. While driving the drift *C* to the northward from the main drift in the 'slough-over' pay-ground, the water from the old works broke through and filled the shaft *A* to a depth of 60 ft. from bedrock. The flow of water, however, was not nearly so heavy as on the Bessie claim. At *B* an old shaft in the flooded ground remained standing; an Emerson sinking pump with a 3-in. discharge was set up in this shaft and the water-level reduced to bedrock. At the same time a new shaft was sunk in frozen ground at *E*, and Worthington pumps of 1½ and 2-in. discharge were installed on bedrock. A drift was then run to the east, the old works were broken into and a block of virgin ground adjoining the old works on the south was stoped out, the water being handled in the meantime by the Emerson pump in shaft *B* and one of the pumps in the shaft *E*. The water pumped from the mine was used in sluicing, and by its aid the work was continued until November 11, although the sluicing elsewhere in the Nome district was over before October 1. This is the latest sluicing of record on the Seward Peninsula; the first sluicing of the season of 1909 was done with snow-water on May 12, six months before. Most of the water for the Dry creek work came from a small reservoir in Dry creek itself; the ice was 18 in. thick over the pond when the stoping was completed, and the sluicing abandoned. The mine-water supplemented the creek-water; each day before starting to sluice, warm water was run through the boxes for a few minutes in order to thaw them out.

While the stoping was going on from shaft *E*, a timber bulk-head was built in the drift *C*, about 8 ft. south of the edge of the stope; the entire drift, about 3½ ft. wide by 5 ft. high, was filled with pieces of timber 8 ft. long, laid lengthwise of the drift. All the chinks between timbers in the north face of the bulkhead were plugged with wedges, and the face was then plastered over with a mixture of snow and water, forming a slush, against which was directed a stream of cold air brought down the shaft *B* by means of a ventilator similar to that used on shipboard. Layer after layer of slush was put on and frozen until there was a thickness of more than 3 ft. on the north or water-side of the bulkhead. The drift *D* was connected with the old works during the course of the stoping from the shaft *E*, but the connection was made through a very small opening; this was frozen up without a timber backing such as was used in the drift *C*. When the pumping at *B* and *E* was stopped and the 60-ft. head of water came against the bulkheads, the one at *C* leaked so badly that it was necessary to pull the water-level down to bedrock again by means of the pump in the shaft *B*, and it was then found that the timbers had not been moved from place, but the slush on the north face had honeycombed instead of being frozen into solid ice and the water-pressure had crushed it, allowing the water to leak through the spaces between the timbers. The timbers were therefore discarded and a new bulkhead built of wet sand, frozen on a little at a time, after the manner shown in Fig. 5. The 6-

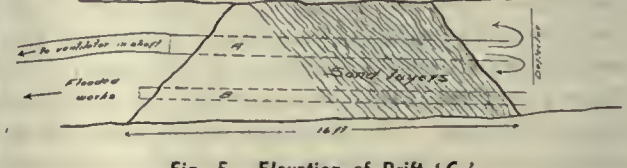

Fig. 5. Elevation of Drift 'C.'

in. iron pipe *B* was set in the base of the bulkhead to furnish drainage for any accumulation of water on the upper side while the bulkhead was being built; the 10-in. iron pipe *A*, 14 ft. long, was set into the centre of the bulkhead and used for conveying cold air from the ventilator in shaft *B* to the lower side of the bulkhead, to which layers of wet sand and small gravel were frozen until the total thickness was about 12 ft. Wooden plugs were driven in both ends of the pipes *A* and *B*. This bulkhead has proved an entire success.

The ice plug at *D*, however, gave way after the new bulkhead had been put in at *C*. The accumulated water in the old works was once more pumped out through the shaft *B*, but the stope had caved so badly that it was no longer possible to reach the drift *D* with a cold-air pipe from the bottom of the shaft. It was the cracking and caving of the stope-walls that brought about the failure of the bulkhead in the drift *D*. The position of this drift was established on the surface by survey, and a hole drilled into it with a Keystone gasoline drill. The depth of the ground at this point is 80 ft. By means of a stream of cold air from the drill-hole a bulkhead was frozen in the drift after the manner shown in Fig. 6. Sacks about half filled with wet sand were used. The first layer *A* was built just north of a low place in the roof, and the upper sacks of the layer were pulled

down until they rested against the projection from the roof. A hammer was used to pack the sacks tightly against one another and against the walls of the drift. When the drift was completely filled, freezing with the cold air was started. About 24 hours' freezing sufficed to harden the first layer of sacks to such an extent that there were no leaks when the drift north of the bulkhead filled with water, but the pump in shaft *B* was kept running and the head of water pressing against the sacks was not allowed to exceed 8 or 10 ft. until two more layers of sacks

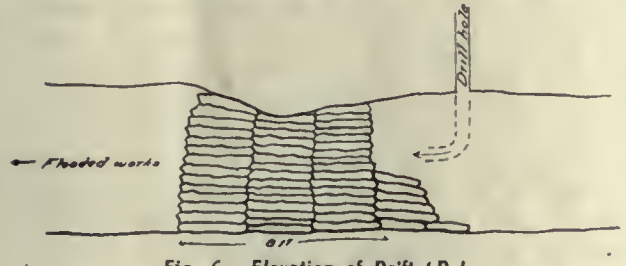

Fig. 6. Elevation of Drift 'D.'

had been thoroughly frozen into place behind the first one. During the five days that freezing was carried on the temperature was generally not below zero. This bulkhead has now been under pressure for several weeks and has shown no signs of yielding.

In comparing the three methods, the ammonia process has the advantage, since it can be used at any season of the year; the first cost of the equipment is greater than that necessary for the other two methods, but the cost of actual operation is about the same. The use of calcium chloride or other solution of low freezing point must be confined to the winter season. The cold-air method can be used only during the winter months, and in workings where the flow of water can be handled at a reasonable cost.

Appropriations for the beginning of the construction on the $11,543,000 breakwaters to be constructed at Colon, Panama Canal Zone, will be available after June 30. Work has already been begun on the service buildings that will be required for the work. There will be two breakwaters. The west one, extending from Toro Point at an angle of 42° 53′ from Colon light, will be constructed first. It will be about 10,500 ft. in length, with a width at the top of 15 ft., and a height above mean sea-level of 10 ft. The width at the bottom will depend largely on the depth of water. The survey of the bottom of the bay along the line of the breakwater showed the greatest depth to be about 43 ft., and at this point the embankment will approximate 180 ft. in width. The east breakwater will be an isolated structure constructed at an interior angle of about 135° to the west breakwater, and will be about 5700 ft. in length, with the other dimensions practically the same as those of the west breakwater. The amount of fill estimated required in the construction of the breakwaters is 4,915,000 cu. yd., about one-half of which will be material excavated on the Point for the core of the west breakwater, and the balance Porto Bello rock. The construction of the inner end of west breakwater will proceed by driving piling for trestle on which a track will be laid and train-loads of material hauled out on it and dumped.

Wet Gold-Assay

By Robert DeLuce

The following is a description of a wet process for the assay of gold which I believe many will appreciate. It enables a man to carry a portable outfit easily to remote places. The necessary apparatus can be carried in a suit-case and need not weigh over 15 lb. The procedure is: make up a solution of 100 parts of water to 2 parts of resublimated iodine and 4 parts of iodide of potassium. This solution is a rapid solvent for gold. Next weigh out one assay-ton of pulp, transfer to a porcelain mortar, add 50 c.c. of the iodine solution, and grind for 10 minutes. Let stand for one hour to insure the solution of all gold in the ore. Should the solution turn clear in the meantime it shows that there is an excess of reducing agent present in the ore, and more iodine and iodide of potassium must be added until the brown color of the solution becomes permanent. Next filter and wash off the iodine solution from the pulp, add to the filtrate 3 grams of mercury, and shake vigorously in a glass stoppered bottle until the solution clears. The gold will then be all precipitated from the solution and amalgamated with the mercury. Transfer the mercury to a porcelain evaporating dish, wash with clean water, and add 10 c.c. HNO_3 and warm gently until vigorous action commences. The mercury will collect in one globule, and finally dissolve completely, leaving the gold in a compact button. Pour off the nitrate of mercury and wash the gold button with distilled water if available; if not, ordinary water, slightly acidulated with nitric acid, will do. Finally dry over a lamp.

The button can be weighed as soon as dry if a button-balance is available. Where there is no button-balance to be had a number of other methods can be used. A form of ivory scale for blow-pipe buttons is calibrated for this kind of button. Also the microscopic method described by Beringer in his 'Text Book of Assaying' can be employed. For the ordinary prospector, however, the following method is probably accurate enough. A number of buttons of different sizes are made and weighed on a delicate balance; they are then mounted on a card with glue and used to compare with the buttons obtained in assaying with the above process. This is adapted to all ores that can be successfully treated by amalgamation, cyanidation, or chlorination. With certain variations it can be adapted to almost any ore. Even an ore rich in copper, by a preliminary treatment with nitric acid to remove the copper, might be tested in this way.

Electric fuses are the detonators used when electrically firing high explosives such as dynamite. Such a fuse consists of a copper capsule or shell containing a detonating charge surrounding a fine platinum 'bridge' which joins the tips of the insulated copper wires of various lengths. The ends of the copper wires are secured in the copper shell by a composition plug which also serves to keep moisture and water away from the charge. The fuse is detonated by passing a current through the copper wires and across the platinum bridge.

FAST TUNNEL DRIVING

During the month of May 1910 the Laramie-Poudre tunnel was driven from two headings a distance of 825 ft. The heading from the west end was advanced 332 ft., while that from the east portal was advanced a distance of 513 ft., thus breaking all American records for a single heading in a calendar month. In January 1909 the Cripple Creek drainage tunnel was driven 435 ft., and in January 1908 one of the headings in the Gunnison tunnel made 449 ft., and in October 1908 the Elizabeth tunnel, near Los Angeles, was driven 466 ft. The rock in the Cripple Creek drainage tunnel and in the Laramie tunnel is very much the same, being hard firm granite in each; whereas in the Gunnison and the Elizabeth the rock was very much softer, and in the latter quite a large portion of it was shale. The rock through which the Laramie tunnel is being run is so hard that 27 holes have to be drilled in the face of each heading and loaded with the most powerful modern explosives to break it successfully. The men work under the bonus system and receive an extra amount of pay for each foot driven over 250 in each calendar month, and on such a record-breaking run as that of last month this bonus amounts to a considerable sum, consequently both workmen and the contractor, James A. McIlwee, are superlatively happy. The Laramie tunnel, as driven, is 7½ ft. high and 9½ wide, and is nearly oval in form, thus obviating the necessity of taking out any corners and affording every possible facility for rapid driving. In fact this was what the consulting engineer, D. W. Brunton, had in view in using this particular form. The undertaking was entirely new, and no makeshift machinery had to be employed, so that in designing the big hydro-electric power-plant there was nothing to be considered except actual conditions, to which every part of the plant was made to conform. The rate of driving as given above is from the official surveys and measurements of Charles R. Hedke, chief engineer for the Laramie-Poudre company, and there can be no question as to the distance driven during the month.

Driving 513 ft. in a single heading in a calendar month is quite an achievement, but when the difficulties under which the work from the western end is carried on, are considered, 332 ft. is almost as good. The Laramie tunnel is driven on a grade of 17%, sloping from the west toward the east, and consequently the material removed from the west end had to be hauled up grade, whereas on the east end the loaded cars run down grade, and only empty cars have to be hauled up. In addition to this, the west-end workings do not run directly out into the open air on grade, but are connected with the surface by a 200-ft. incline. This was done to avoid about 1400 ft. of water-bearing rock and wash which, had it been opened up, would have drained directly down the tunnel into the heading. Even with this precaution a considerable amount of water seeps in and has to be pumped, so that when the difficulties of pumping, up-hill haulage, and hoisting through an incline are considered, it will be seen that the 332 ft. driven on the west end is a creditable performance.

SOLVING THE SMELTER SMOKE PROBLEM

By A. H. Martin

The bag-house under construction for the Mammoth Copper Co. will contain 2960 wool bags, each 18 in. diam. by 30 ft. long. The smoke from the blast-furnace flues will be drawn by two 400-hp. fans into the discharge chamber. From this it will pass through 38 cooling pipes into the bag-house discharge department. The pipes are each about 200 ft. long, and will reduce the temperature of the smoke from 400 to 200°F. From the discharge chamber the smoke will pass into the series of bags by ingress through the iron floor, and will ultimately discharge into the atmosphere by means of a number of small stacks. Zinc oxide feeders are attached to the fans, which will be used whenever free sulphuric acid is carried by the fume, zinc oxide being fed to neutralize the acid. Before the gases leave the bag-house free air will be drawn in and the fume diluted to such an extent that any portion of harmful smoke escaping the bags will be so diluted as to be harmless. About 1,526,420 lb. of structural steel will be used in the construction of the bag-house, and its total cost will approximate $300,000. The materials are being furnished by the American Bridge Co. of New York and St. Louis.

The Balaklala Copper Co. has decided to install the Cottrell fume-controlling device, invented by F. G. Cottrell, of the University of California. In this method the solid particles, which cause the damage to crops, are separated by electric-discharge. The plant will have an electrode area of 100 sq. ft., and is designed to handle 70,000 cu. ft. of smoke per minute. The device consists of a precipitating chamber in which are placed 126 electrodes. These are strips of iron 4 ft. long by ¾ in. wide, with saw teeth their entire length. Between the electrodes are placed flat plates of iron about 6 in. wide. An electrical current of 27,000 volts is delivered to the electrodes, and as the smoke circulates between the positive and negative electrodes the solid particles are precipitated on the adjacent plates. The experimental plant shows that 90% of the solid particles carried by the smoke is precipitated by this method. The gases from the main flues are drawn into the precipitating chamber and are driven into the main stack by two fans 186 in. diam. The wheels are 90 in. diam., and the combined capacity is 500,000 cu. ft. per minute. There will be nine permanent units in the plant, seven for constant service, and two for reserve purposes. The total cost will approximate $100,000.

Tin was first discovered in the Black Hills of South Dakota in 1876, when Richard Pearce, of Denver, recognized cassiterite in the placer gold from the northern part of the hills, and in 1877 Fred J. Cross identified it in the material from Elk gulch in the southern hills. It was not discovered in place until June 1883, when A. J. Simmons, of Rapid City, sent specimens from the Etta mine, two miles south of the Keystone, to San Francisco for determination. The Etta claim was at that time being prospected for mica. Shortly afterward tin was found in place at Nigger Hill, since called Tinton, but at that time well known for its rich gold placers.

Mining on the Mother Lode in Amador County, California

By William H. Storms

When Alvinza Hayward first came to Sutter Creek, in the early fifties, his capital consisted of a few hundred dollars in money, indefatigable perseverance, a keen insight into the character of men—particularly their weaknesses, and a splendid faith in his own ability to accomplish anything he undertook. His optimism was by no means limited to the size of his purse, as he was soon to demonstrate in his early operations on the Mother Lode. The great Lode was at that time wholly an unknown quantity. It was recognized that a great gold-bearing belt extended through the foot-hill region of the Sierra Nevada for a hundred miles or more, but beyond this nothing was known of it. Quartz mining was

Eureka Consolidated Mines, Sutter Creek, California.
(From an old photograph.)

new, nothing beyond the superficial development of a few veins having as yet been undertaken. Placer mining had been carried on with vigor throughout nearly all the counties along the west side of the Sierra, and the miners had learned rapidly in that expensive school, experience, how to work gravel mines.

It was early learned that the gold in the gravels, both those of the modern deposits and of the 'ancient deep rivers', came from the quartz veins and rocks over which these streams had flowed. The unsolved problems in quartz mining were largely mechanical. Already from Grass Valley to Mariposa, several quartz mines had been equipped with rude hoisting, pumping, and milling machinery, and several disastrous failures had resulted. One mine, the Seaton, I believe, near Drytown, in Amador county, was equipped with a steam-engine which had driven the paddle wheels of a steamer that came around 'The Horn'. None of the machinery of those early days was at all suited to the duties required of it.

One of the first mines was located and exploited in Amador county in 1851. It was owned by several preachers, and was known as 'the Ministers' claim'. This was the Spring Hill mine, now a portion of the famous Keystone at Amador City. The ministers bought a steam-engine to operate their mill, the mine being worked through an adit. The engine was built to order in Sacramento. The main shaft in the mill was a stick of timber having gudgeons of round iron driven into auger holes in the ends for bearings, these ends being strengthened by bands of strap-iron. Cams were improvised by driving bars of iron into the wooden shaft, their outer ends being bent downward somewhat to reduce friction. The stamp-stems of wood were square, and tappets were provided by driving spikes into the stems at proper height. The revolving cam-shaft raised these rude stamps, which dropped in succession, crushing the quartz in the wooden iron-lined mortars. The stamp-heads were shod with iron. In lieu of plates below, the sand from the mortars flowed through a rocker 8 ft. in length, which was kept in motion by a crank connecting with the clumsy cam-shaft. This crude mill proved unsuccessful, but was a few months later replaced by a better one which embodied such improvements as were suggested by experience.

The first mill in which amalgamation with quicksilver was tried was near the Spring Hill, and for a time proved a dismal failure, but later, it being learned that the 'quick' contained a quantity of lead, the condition of the mercury was improved by retorting, and the saving of gold thereafter became much more satisfactory. Quartz mining now engaged widespread attention. The most extravagant ideas were entertained of the value of the ore, and its wealth-producing potentialities were thought to be unlimited. To such an extent did these optimistic opinions obtain that many favored reducing the size of claims from 240 to 120 ft. along the Lode, with two extra claims for the discoverer of a vein in a new district. Some declared the quartz contained a dollar a pound, which the conservative ones were unwilling to admit, stoutly contending that it would not go over a thousand dollars per ton. At a convention held at Rancheria, July 7, 1851, Mr. Davidson, one of the preachers owning the Ministers' claim at Amador City, advised moderation in these estimates, and said that in his opinion, and having no desire of deceiving them, the rock would probably not average over ten cents per pound, though he believed this estimate to be conservative. He was undeceived when he started his mill at the Spring Hill a few days later. Still, this mine with its rude equipment was sufficiently rich to pay not only extravagant expenses, but handsome dividends as well.

Not every mine on the Lode had a bold outcrop; some that did have never proved profitable. Among the rather obscure veins was that of the Badger mine just south of the town of Sutter Creek. The Wolverine, joining the Eureka on the north, was one of those having a solid outcrop of iron-stained quartz 5 to 12 ft. in width and 200 ft. or more in length. Yet the Wolverine was never largely profitable, whereas the Badger and Eureka were.

Alvinza Hayward at this time associated himself with a man named Robinson, who owned the Badger mine, named after his native State of Wisconsin. Together they opened the mine to a depth of a hun-

dred feet or more, and for a time it paid well; so well that they were enabled to provide a better hoisting plant and also to build a small mill. About the time Hayward and his partner had succeeded in getting their property suitably equipped, the grade of ore became too poor to longer yield a profit, the expenses of mining and milling exceeding $12 per ton. Then followed dark days. For a time both men stayed courageously with the losing venture, hoping that pay-ore would again be discovered at greater depth. The shaft was sunk deeper, but the ore got poorer rather than better, and Robinson, disgusted with the lack of success when so many seemingly better opportunities presented themselves, left the Badger mine and his partner, to win fortune for himself under more encouraging conditions. Here Hayward's tenacity of purpose showed itself. He could have gone to any one of a score of other places and doubtless have done better than he was doing with the Badger, but he had started to develop the mine and was unwilling to give it up until he had thoroughly satisfied himself that further work would be folly. He went as far as his limited means would admit, but the much wished for pay-ore remained undiscovered. When his money was all gone and his credit heavily taxed, Hayward was visited one day by Oscar L. Chamberlain, his one time partner in the placer mines in Calaveras county. Chamberlain had been successful in the humble business of raising potatoes on his ranch in Calaveras and had just sold out for $6000 and was about to leave for his Eastern home. Hayward took him through the workings of the Badger mine, expounded his theories and expressed his faith in the future greatness of the property with so much force that he finally talked Chamberlain into joining him and putting in his $6000. Chamberlain frankly said he considered it a desperate chance, more likely to fail than to succeed, but philosophically remarked that as the miners would still want to buy potatoes if the mine failed, they could go back to the unromantic occupation of growing 'spuds' for the miners who were successful, and moreover, he did not like to desert his old partner in the hour of his distress.

Development of the Badger mine was now continued with renewed energy under the stimulation of Chamberlain's money, but $6000 does not go far in the development of an unprofitable mine, and the sum was quickly absorbed. Credit was the only thing now left to the owners. They went ahead on this basis until finally only one man, John Keyes, of the firm of Clute & Keyes, was willing to carry them. Eventually Hayward and Chamberlain owed nearly $100,000, and merchants, ever liberal and well disposed toward men of the type of Hayward and Chamberlain, could carry them no longer. The partners worked harder than any man in their employ. When fuel was low, Alvinza Hayward was repeatedly known to go up on the hillside and 'pack' down enough wood to keep up steam at the hoist until he could persuade someone to trust him for a cord or two of wood. They owed thousands of dollars to their miners, but for some reason these men appeared to share the faith of Hayward in the ultimate success of the mine and continued to work as well as though they were being promptly paid.

One Sunday morning Hayward and Chamberlain were sitting in front of their cabin, which also served as an office, a few yards from the shaft. They were sitting in front of their cabin, which also for, as Chamberlain put it, they had "reached the last ditch." They noticed a group of miners near the shaft engaged in earnest conversation. After a few minutes, several men left the group of miners and slowly walked up the hill in the direction of the office. "Jig's up!" was Hayward's terse remark. "Looks like it," was his partner's equally laconic response. The men approached and one of them, in the capacity of spokesman for all, said: "Mr. Hayward, we have stood by you till now without money for months, and we are willing to stand by you a while longer, but the boys say they can't work without some tobacco."

"All right, boys," responded Hayward, "I'll see that you get some tobacco."

The men returned to their companions and the shift went below. Hayward turned to Chamberlain and said, "You must go to Jackson and buy a box of tobacco for them. Here's my watch. You can raise enough money on that—these men must have tobacco."

A few days later the shaft came into rich ore. Nothing was said to the men about it, but the work was urged on with greater vigor than ever. Hayward found that the shoot was pitching northward into the Eureka ground adjoining. Robinson had gone away in the spring of the year 1857, but now returned in the latter part of September of the same year. Meeting Hayward, that gentleman complained bitterly of a lack of success, but at the same time expressed his intention of staying with it, and pretended that he wanted Robinson to put up more money, which the latter refused to do. By the exercise of considerable finesse, Hayward managed to successfully bargain with Robinson for his interest in the Badger and finally bought it for $7500. Hayward continued to work the mine, but still carefully refrained from making any outward show of success until late in the fall, when he allowed the fact to leak out that he had 'struck it rich' in the Badger mine. Robinson was suspicious, declaring he had been defrauded, and for a time threatened to take summary revenge on his scheming erstwhile partner. Hayward flatly denied any underhanded work, and after much bickering and the intervention of mutual friends, a reconciliation was effected, which was made still more binding by a present of $1000 from Hayward to Robinson's son at Christmas time. A love feast followed. Hayward bought a keg of beer, and he, with Robinson, proceeded with many friends to blithely celebrate the occasion. The bar-tender failing, after numerous liquid rounds, to draw the cheering beer with sufficient promptitude, Hayward undertook to expedite matters by knocking the spigot from the barrel, whereupon the beer spurted in all directions and much of it was wasted. As an improvement on the removal of the spigot, Hayward smashed in the head of the keg with a heavy hammer, and free beer was then readily accessible to all. Everybody directly concerned in the performance promptly imbibed to the extent of his capacity, and

in most cases they exceeded it. Hayward and Robinson now walked around town with joyous faces, their arms entwined, Hayward the while industriously ringing a good-sized dinner bell. The reconciliation was certainly celebrated in true Western style.

The rich ore was promptly sent to mill, and with the proceeds control of the Eureka mine was secured for a few thousand dollars, and it is commonly said that much of the money for this came from the Eureka ground, the Badger workings having extended over the line into the neighboring mine. There now being no further reason for secrecy, the ore was sent to both the Badger and Eureka mills, and to custom mills as well, and soon the Eureka Consolidated, which a short time before was one of the poor mines of the Lode, was making an output of over $30,000 a month. Chamberlain, seeing his fortune was now made, did not care to further follow the business of practical mining and sold his interest to Hayward for $500,000, being well satisfied with his investment of $6000, and retired from the mining regions to lead a life of luxury.

The richness of the great Eureka-Badger vein is still one of the favorite topics of conversation among old timers. One miner told me a few days ago, that one day in the stopes he hammered a boulder of hard rock for nearly half an hour, and being unable to break it, finally managed to send it up in the bucket. In a few minutes the superintendent came hastily to where he was at work and excitedly inquired where the boulder came from. The cause of his excitement was in the fact that the quartz was matted with gold to such an extent that it was with greatest difficulty it could be broken, which fact, curiously, the usually astute miner had failed to notice, the rock being covered with the coal-black gouge of the vein. Some of the less scrupulous miners used to add to their wages by occasionally appropriating small pieces of quartz containing gold. It need not be said that modesty was not always a feature of these appropriations; in fact, some of these men actually amassed fortunes by crushing the loot of the mines in their little private mills, consisting of a cast-iron mortar and pestle, which they employed industriously in their cellars or in small drifts leading from them. Several years ago, a boy at play on the hillside near the Eureka mine observed what appeared to be an old pair of overalls lying beneath a bush. He gave it a pull and the rotten cloth was torn, having lain there evidently many years. When the cloth was torn away, a quantity of rock was exposed. The lad was raised in a mining town, and his eye quickly caught the glint of gold. Examination revealed gold in every piece. This find is said to have netted $6000. Some miner had cached his spoil where it was found, doubtless hoping to remove it later.

Most miners, like sailors, are superstitious. Of course, intelligent people generally have little sympathy with these ideas; nevertheless, the following strange story is absolutely true, and will be vouched for by some who are still living at Sutter Creek: One morning at breakfast in the company boarding house, a miner named Wilson White said that during the night he had had a vivid dream that depressed him somewhat. He dreamed, he said, that three men were climbing out of the mine on the ladders when the one nearest the surface lost his hold and fell, knocking the two men beneath from the ladder. Two were killed and the third seriously injured. His friends, more superstitious than White, declared his dream a bad omen and urged him not to go into the mine that day, particularly as it was the last shift he expected to put in there, but he refused to give heed to their well-meant remonstrances and went to his work as usual, laughingly saying he was not in the least superstitious. That evening Wilson White, a man named Joseph McDaniels, but who was generally known as 'Joe Kentuck', and a third miner whose name is now unknown, were climbing the ladders of the inclined shaft on their way to the surface. For some reason which can never be known, Wilson White, who was ahead and nearing the surface, lost his hold and fell backward headlong down the shaft, bounding from place to place among the timbers. His falling body struck the man who had followed him a few feet below, and he, too, fell from the ladder. Joe Kentuck was on the ladder, but not, as yet, a great way from the bottom. He apparently received some intimation, possibly from an outcry of one or both of the unfortunate men, and clung desperately to the ladder. One of his falling companions struck him, but so tenaciously did he grip the ladder that he maintained his position. Wilson White and the man first below him fell to the bottom of the shaft and both were instantly killed.

The great mine daily grew greater and richer and soon became the then most valuable gold mine in the world. Larger and better mills were now built, and the famous Consolidated Eureka mine continued to output gold at the rate of more than a million dollars annually until its total production exceeded $20,000,000.

It was in the Consolidated Eureka mine that giant powder was first introduced. A man named Birdsall, formerly employed there, took the agency for the powder company, but so great was the prejudice against it that it was with great difficulty that the miners could be persuaded to use it. Nevertheless they quickly recognized its superiority over black powder, particularly its convenience in wet holes, and stole it for use on contract work whenever opportunity offered.

In some respects, the Eureka-Badger vein was geologically unlike most of the other mines of the Mother Lode. The vein occurred at the contact of a greenstone (diabase tuff) hanging wall and clay slate foot-wall. It is said the hanging wall continued unbroken from the surface downward with wonderful regularity to a depth of 1750 ft., where it appeared much broken and disturbed. The mine has now been closed for many years, and geologists of this day have had no opportunity to study its structure, except at the surface, so the cause of the reported disturbance about the 1750-ft. level, I am unable to explain. The great Eureka mine has for many years been the property of Hetty Green, of New York, and she seems disposed to allow it to remain idle, although many overtures looking to its purchase have been made by California mining men and others.

Crushing Efficiency of Fine-Grinding Machines

By H. Stadler

*Crushing means reduction in size, consequently in volume, and the possibility of an exact size measurement of the materials dealt with before and after passing a machine is, therefore, the primary factor upon which the reliability of the computation of crushing efficiency of grinding appliances depends. The classification of the sizes obtained by sets of screens into series of standard grades, may be based on the largest diameter, on the volume (or weight), or on the surfaces (or fractures) exposed. It does not matter which of these functions of the particles be taken as a base for the classification into grades, as the final results of the calculations are bound to be the same for all classes, but once a system has been adopted it is necessary to stick to it by reducing all other fuuctions to the same standard of measurement. It would, for instance, be utterly wrong to base calculations of crushing efficiency on the surface, and at the same time measure them by quite another rule based on the reduction in volume. Volume and surfaces vary with the coarseness of the particles at quite a different ratio, and without converting the one into the other they cannot be measured by the same rule any more than the pressure in a steam boiler can be measured directly by degrees of temperature without conversion. Considering that after crushing, the further or-treatment by amalgamation or by cyanidation has to act through the surfaces, it has been suggested that the exposure of these surfaces, representing the 'metallurgical efficiency', should be taken as a criterion of the useful work done in crushing. Under the condition that the work done represented by the exposure of surfaces is also measured by a standard of grades, based on equality of steps in regard to these surfaces, no other objections than those of practical inconvenience can be raised against this suggestion. However, as cyanide managers do not trouble about the surfaces exposed, and as also the assayers give the percentages of gold extraction per weight (volume) and not per fractures exposed, there is no reason why, in computing crushing efficiency, the reduction in volume should not also be accepted as representative for the metallurgical efficiency.

The most rational and logical system of classification for mining purposes is, therefore, undoubtedly to base it on the reduction of the volume of the particles. It appears that the standard screens of the Institution of Mining and Metallurgy follow, in regard to the mesh-apertures, a curve of seriation based on a successive reduction in volume of one-half from grade to grade, but unfortunately, in consequence of unreasonable concessions made to the accustomed number of meshes and to the maintaining of the uniformity of the screen-discharge area—the distance between the screens, or, better, the decrease of the grades in regard to volume, is very irregular and not based on any principle. By chance, however, it was possible to select from the large number of these standard screens a restricted set with apertures corresponding fairly well to the mathematically correct scale, and complying, at the same time, with the requirements of equality of steps from grade to grade in regard to a reduction in volume of 1 to 4.

The possibility of an accurate measurement of grinding products being ascertained, the next question arises of establishing from the gradings taken at the inlet and at the discharge of the machine a workable and reliable formula for the computation of the useful work done in crushing by the machine. It has been shown that the amount of work required to reduce the equivalent of 1 cu. in. from one grade to the next following is constant, and the ordinal numbers of the grades represent, therefore, at the same time the relative values of the energy which had to be spent in reducing the unit of 1 cu. in. to the respective grade. To obtain the mechanical value of mixed sands, multiply the percentages of the gradings with the number of these energy or crushing units of the respective grade, and add the products. The relative value of the work done by any crushing machine is naturally determined by the difference between the mechanical values of the pulps at the inlet and discharge of the machine, and the relative mechanical efficiency is then the product of this value into the tonnage dealt with, divided by the value of the energy-consumption.

In practice this method, based on Kick's law, has given great satisfaction, and all through the research work which I had to execute on behalf of the Mines Trials Committee, in tube-milling, it was seen that this method is for coarse as well as for fine crushing, correct and reliable, and in accordance with the results of experience. Based on this fact, I have no hesitation in stating that with this method it is now possible to determine, with a high degree of accuracy, the relative merits of different crushing appliances or the mechanical efficiency of one and the same machine working under varying conditions.

*Abstract from Jour. S. African Ass'n. of Engrs.

Plans for geological surveys in Alaska this season include a continuation of the work done in the Innoko field in 1908, the results of which have been published in Bulletin 410 of the Geological Survey. It is now proposed to make a geologic and topographic reconnaissance survey of the more important part of this placer district, including the northern part of the Iditarod basin. This work will be done by A. G. Maddren, geologist, and C. G. Anderson, topographer. The party will make its way inland by way of the Yukon river, and one section, with seven horses, will be landed at the mouth of Ruby creek. This section will travel overland to the Innoko and on the way will undertake such surveys as can be made without delaying the party. In the Innoko placer district an areal survey will be begun and carried southward as far as conditions permit. A second section of the party will continue down the Yukon and up the Innoko, bringing supplies to meet the first section on Ophir creek. The water resources available for placer mining in the Yukon-Tanana region will be further determined by C. E. Ellsworth and G. L. Parker, who began work in the Fairbanks district in April and later extended it to Circle.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Classification of Igneous Rocks

The Editor:

Sir—I send you with this an abbreviated tabular classification of igneous rocks which may prove of interest to some of your readers.

Classification of Igneous Rocks, by E. R. Rice.

Richard Gird and His Work

The Editor:

Sir—Richard Gird, who died in Los Angeles on May 29, was a fine type of the men, now mostly passed away, who did much to open the mining interests of the Pacific Coast. A morning paper, in a fine editorial notice, said "he was a man who did things." "Any community in which he lived was better because of his presence." I remember that while standing under a cluster of great walnut trees in Sonoma county once he said he had planted them over fifty years ago knowing someone would be benefited later. Another time, going by rail from the Kern to the Coalinga oilfields, he looked out at one point, saying he once owned a section of land there, and put hundreds of hogs on it because Mussel Slough settlers were then poor and harrassed and needed an object lesson in what might be done. Many of the hogs were given away, some disappeared, and the rest were disposed of.

He made the first map of Arizona; laid out the city of Prescott, took the first irrigating ditch from the Colorado river, and early erected a matting furnace at the Planet mines. While engaged continuously in mining, his principal fame came from discovering, with E. L. and A. E. Scheffelin, the lodes worked by the Tombstone Mill & Mining Co. He assayed and tested the ores himself and built the first mill in the district, while other companies waited until the 'Gird mill' successfully turned out Dorè bars. He made a fortune out of these mines, and coming to California, purchased the Chino ranch of 42,000 acres, fenced and stocked it, steadily improving the breeds. Then he erected a laboratory and systematically analyzed the soils, with the result that he became the 'father of the beet sugar industry of the State.' Meantime he helped many men and put them on the road to prosperity. He sunk artesian wells on his ranch, and when an acquaintance came to him saying that if he could get the use of a string of tools he thought he might strike oil in Kern county, the tools were furnished, and this was the beginning of one of the largest oil fortunes of the State. Other acquaintances had borrowed a large sum from an Eastern financier to equip their gold mine, and came near losing their property in consequence, whereupon they applied to Mr. Gird; the finances were adjusted, the debt paid, and the original owners are still operating their property.

Up to the end he was interested in mines in Mexico, Arizona, and California, using his own funds in development. He was the kind of conservationist who made two blades of grass grow where was but one before. " 'Tis true 'tis pity and pity 'tis 'tis true" that in the great mining operations of today conducted on a scale impossible for any individual to undertake, and with an efficiency and economy unknown in pioneer days, there seems little place for a man like Richard Gird.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Copper deposits near Yerington are of three kinds. (1) Irregular bodies formed by metasomatic replacement of limestone and genetically associated with metamorphism of a kind usually attributed to the contact action of intrusive rock; (2) metasomatic vein deposits in altered limestone; and (3) metasomatic vein deposits in granodiorite.

Specular hematite in Virginia occurs inter-layered with the Lower Cambrian quartzite and shale as a bed of varying thickness. Workable portions outcrop along the Blue Ridge in Botetourt, Bedford, and Roanoke counties, from Buchanan on the north to a point about five miles south of Roanoke. The ore-bed has been worked at eight localities along its principal outcrops.

A treaty has been signed by Great Britain and the United States in which provision is made for regulating the use of water for power purposes at Niagara Falls. By the terms of the treaty the Canadians are to be permitted the use of 36,000 cu. ft. per second, while on the New York side 20,000 cu. ft. per second may be used. The amount allotted to the Canadian side will make possible a much larger development than is now in use, but as the developing companies are permitted by the Canadian, as well as by the United States authorities, to transmit and sell on the south side at least half of the power generated in Canada, the New York side is benefited by the Canadian development.

Graphite is used for the manufacture of crucibles, as a lubricant, in the manufacture of pencils, as a pigment, for coating foundry castings, in the manufacture of electrodes, and for numerous minor purposes. The grades are: amorphous, crystalline, and artificial. In 1908, 11,456 tons valued at $762,367 were imported; 1443 tons of amorphous, valued at $75,250, and 1144 tons of crystalline, valued at $132,840, were produced in the United States. It is now quoted in New York at 5 to 10c. per lb., depending on purity, size, and character of crystallization. Graphite occurs usually irregularly disseminated through schists and the process of treatment is one of crushing, sizing, and close concentration. A market should be sought according to the purity and particular adaptability of the grade found.

The weight of the dry matter in a cubic foot of wet mud of the density to be expected at the bottom of a reservoir was determined by the engineers of the Tallahatchie drainage district, Mississippi, in connection with their investigations of the probable sedimentation in the reservoirs that may be constructed in the district. Two sections, 8 in. long, of 3½-in. wrought-iron pipe, were turned on a lathe to a cylinder bore inside, were milled at the ends, beveled outside at one end, and carefully measured with calipers and scale. Each tube was pushed down into typical submerged mud, struck at the ends, and the contents then washed out into an iron vessel, which had been first heated to drive off moisture, and then weighed. The vessel was then heated until all moisture had been driven off, and again weighed. By several such determinations it was ascertained that 1 cu. ft. of wet mud such as was tested contains 60 lb. of dry matter.

Manganese ores in the United States generally occur in small discontinuous pockets, few of which contain more than 25,000 tons, and most of them much less. A large proportion of the ore is low grade, containing considerable iron, silica, and phosphorus. The Eastern ores are embedded in clay and must be washed and sorted before becoming fit for the market. The limited extent of the deposits discourages the erection of expensive concentration plants; hence mining is carried on only in a small way.

A reinforced concrete building in course of construction in Mexico City was subjected to the earthquake shock of July 30, 1909. The second floor was less than two days old when the shock occurred. The projecting rods at the column points and in the outside wall swayed violently, this being noted by the architect and the superintendent of construction, who were on the building when the second of two rather heavy shocks occurred. As in the case of a number of structures built in Mexico City during the past few years, the entire building is carried upon a heavy reinforced concrete raft, which reduced the pressure on the soil to about 800 lb. per square foot. Examination of the building after the shocks failed to disclose any cracks even in the green concrete.

Manganiferous silver ores occur at Leadville, Colorado, in large deposits at or near the contact of porphyry and limestone, replacing the latter. These deposits consist of a black mixture of manganese and iron oxides with lead carbonate and silver. The manganese content varies from 10 to 40%, being high where the iron is low, and conversely. Manganese and iron oxides are associated only with the oxidized portions of the Leadville deposits. In the lower unoxidized portions the minerals are mainly pyrite, sphalerite, and galena. Manganese minerals are conspicuously absent, and it is believed that the large quantity of manganese oxide in the oxidized ore is due to infiltration from the porphyry. The ore is used both in the steel industry and for fluxing.

The Mexican Government has signed the concession for the construction of a railroad from the Isthmus of Tehuantepec to connect with the United Railroads of Yucatan at the city of Campeche. The road is to be built by the Vera Cruz, Tabasco & Campeche Railway Construction Co. The location of the proposed road is not complete, but the company expects to send out an engineering party at once and have the route completed and agreed on before the expiration of the six months' time limit. Two routes have been suggested, the first for the road to keep close to the foothills, thus avoiding much of the lowlands to the north, at the turn of the Yucatan peninsula. The other is to penetrate the lowlands farther to the north, the road thus passing through some of the biggest and most important cities in the hot country, between the isthmus and the peninsula.

Special Correspondence

DENVER, COLORADO

Favorable Season. — Labor Troubles. — The Coal Industry. — Clear Creek Companies.—Cripple Creek News.

Mining throughout the State is in a flourishing condition, as the season is one of the earliest in the history of the snow-bound camps. Leadville mines are now more active than at any time in the last three years. The cheap power furnished by the Central Colorado Power Co. and the draining of many of the former producers by the Yak tunnel promises a most prosperous season for the mines in this district. In the San Juan district, the prospectors have already started out on their annual pleasure trips. The railroads are now open and doing a heavy business in supplies and ore shipments. Roads are even now in fair condition, so that freight teams are hauling ore from many of the mines not on the railroads. The strike of the coal miners in the northern coalfield is dragging along in a sort of hopeless way, with no prospects of an early settlement.

Idaho Springs, Colorado.

The position of the miners has been much weakened by the failure of the national organization to provide the benefit funds promised at the beginning of the strike. On May 28 the laborers, tappers, and furnace men employed at the Globe plant of the A. S. & R. Co. went out on a strike suddenly. They demand more wages. There seems to be no organization and no demands had been previously presented. Considerable damage will result by reason of their sudden leaving. An important transfer of property has been recorded at Durango by which the Southern Pacific railway has acquired the holdings of the Porter Fuel Co. The price said to have been paid is $1,250,000. This property will be remembered as the one on which Joseph Walker, United States Civil Service Agent, was working at the time he was murdered. The transfers made during the past year indicate that the titles to the land have been cleared. The Yankee Fuel Co. of Trinidad is in financial difficulties again, as shown by the filing of a suit by the United States Mortgage & Trust Co. of New York. The latter asks that a receiver be appointed and alleges that the company is insolvent. It is claimed that attempts are being made to dispose of the properties without the sanction of the New York company, which holds a mortgage of $2,500,000 on properties located in Las Animas county, Colorado, and in Colfax county, New Mexico. A new company, known as the Continental Coal & Coke Co., was incorporated here on May 24, with a capitalization of $3,000,000. It has extensive holdings of coal land in Routt county and controls the rights for the Lowe coking process in Colorado. The company plans to establish small coking plants in different cities throughout the State where it can dispose of the gas produced in making coke by this by-product coking process for domestic use. Unusual activity is manifest in the Clear Creek district. Many transfers of property and reorganizations of old companies are being brought about. One of the largest of these reorganizations is that of the Consolidated Vindicator Mines Co. of Idaho Springs. The company has acquired 27 claims on the ridge between Chicago and Soda creeks. Most of these claims were formerly owned by the Gold Leaf, Grass Roots, and Gold Hill companies. The promoters of these companies got into the Federal courts some years ago because of their alleged fraudulent methods, and, as a result, good prospects have lain idle for a long time. Many of those interested in the new company were stockholders in the old companies. The Golden smelter is again in operation after three years of idleness. The North American M. & S. Co. has re-equipped the entire plant and brought it thoroughly up to date. This plant has taken over the business of the Modern smelter near Denver, which plant has been closed indefinitely. The expected boom in Cripple Creek stocks has started on the Colorado Springs Mining Exchange. Rich discoveries in some of the deeper workings of the Elkton, Vindicator, and Golden Cycle started the excitement. A line for an aerial tram from Cripple Creek to the Golden Cycle mill in Colorado City has been surveyed, and estimates on the cost of such a project are being made. Many believe this to be part of the game to get more advantageous freight rates from the Colorado Springs & Cripple Creek District railway. The Deep Drainage tunnel advanced 393 ft. during May. It is still in Pikes Peak granite and making little water. During May, the production from the mines of the district was 57,105 tons with a gross value of $1,351,852. That high-grading is not entirely abandoned is evidenced by the arrest of four of the employees of the Golden Cycle mill at Colorado City recently. Their thieving had been going on for some four months. They will be punished under the recently enacted statute which makes high-grading in this State a penitentiary offence.

TORONTO, CANADA

Peterson Lake Changes Directors.—Cobalt Developments. — Gowganda Shipments. — Canadian Northern Coal.—Canadian Steel Corporation.—Industrial Training.

The most sensational event of an otherwise very dull season in connection with mining matters has been the end of the protracted struggle for control of the Peterson Lake Mining Co. For some time this company has been involved in a series of disputes, culminating in litigation with the Nova Scotia, which holds a lease of a portion of the Peterson Lake property. One of the suits was settled by arbitration, while another is still pending. There has been much dissatisfaction with the directorate, and shareholders have been deluged with circulars from the opposing factions. At the annual meeting on May 30, after a very exciting day, the insurgents won, and almost a clean sweep was made of the old board of directors, a slate headed by Sir Henry Pellatt being returned by a narrow majority. A resolution was adopted favoring the policy of extending the leases. So far the change has had no perceptible effect upon the stock. All expectation of any improvement in market conditions until next fall seems to have been abandoned. Midsummer is too near for anything like a boom. The Provincial mine on the Gillies Limit, sold by the Government for $113,000, is showing good results under the present management, two good veins having been cut in a drift and at the bottom of the shaft. A discovery of high-grade ore has been made on the large vein of the Wyandoh, and another of ore running 2000 oz. per ton. The McKinley-Darragh has declared its regular quarterly dividend of 3%, with the addition, for the first time, of a 2% bonus. A new vein, known as the Victoria, was recently found on the Crown Reserve, 63 ft. south of the Carson vein on the 100-ft. level. It is 2 to 6 in. wide and assays 6000 oz. per ton. The O'Brien has made another shipment of silver bars to England, containing 18,250 oz. fine silver valued at $9675. The Temiskaming has two drills in operation putting the main shaft down to 500 ft., which will make it the deepest mine at Cobalt. The shaft at present is down below 450 ft. The Trethewey has opened new territory at the

150-ft. level of No. 2 shaft. The new vein cut at the 75-ft. level has been struck again at the 150-ft. A drift driven on a stringer ran into 2 in. of high-grade ore with good milling ore for several feet. Skips from No. 2 shaft are now running regularly up the 650-ft. tramway to the mill, which is running nearly to full capacity. The Cobalt Central is in liquidation, but mining is being carried on actively and the mill is in operation. A considerable amount of ore is blocked between the third and fourth levels. There is a 3-in. vein of high grade for about 100 ft. on the fourth level. At the Hudson Bay mine a new vein carrying smaltite and native silver has been found in a cross-cut running southeast of the drift on No. 6 vein. It will assay 2000 to 3000 oz. silver per ton, with leaf silver in the wall-rock. Shipments from the Gowganda district to date for this year total 334 tons, of which the Millerett has sent 218 tons, Reeve-Dobie 42, and Boyd-Gordon 30. The latest addition to the list is the Bonsall of Miller Lake, which last week sent 10 tons to the Deloro smelter.

.William Mackenzie, of the Canadian Northern railway, who has just returned from England, has secured loans amounting to $41,700,000 for various undertakings in which the railway is interested, including $14,000,000 for the Dunsmuir collieries, British Columbia, and $6,000,000 for the development of the Brazeau coalfields, Alberta. The subscriptions for the bonds issued in connection with the latter enterprise were taken up in Belgium. D. D. Mann, vice-president of the Northern, has left for the Pacific Coast. A long projected scheme for the merger of several steel and iron companies, chiefly in western Ontario, is being carried into effect. Application has been made for a charter for the new concern to be known as the Canadian Steel Corporation, and is capitalized at $25,000,000, with headquarters at Hamilton, Ontario. The companies embraced include the Hamilton Steel & Iron Co.; the Canada Screw Co., of Hamilton; the Canada Nut & Bolt Co., of Toronto, with works also at Brantford and Gananoque, Ontario, and the Montreal Rolling Mills Co. The scheme involves extensions to the plant of the Hamilton Steel & Iron Co., including another blast-furnace and a steel-rod mill requiring an expenditure of about $1,500,000. Rumor has it that this merger foreshadows an amalgamation of the newly organized corporation with the Dominion Steel & Coal Corporation, and perhaps other interests, and while this may be premature so far as any well defined scheme is concerned, it is certainly among the probabilities of the future. The Canadian Government has appointed a royal commission on industrial training and technical education, with James W. Robertson, of Montreal, as chairman, among the members being representatives of the Canadian Manufacturers' Association and the Dominion Labor Congress. They are first to investigate conditions in Canada and afterward to visit the United States, England, and the European continent to note the operation of the system in practice and compile information. The subject has been for some time urged on the attention of the Government both by the manufacturers and the labor bodies, but in view of past experience it may well be doubted whether the appointment of a commission is auspicious of the intention of the Government really to accomplish anything practical. Commissions in the past have usually been a convenient expedient to avoid taking action.

JOHANNESBURG, TRANSVAAL.

Randfontein Estates Changes. — General M. & F. Corporation.—Cinderella Deep. — Roodepoort United.—Rhodesia.

Something of a sensation has been caused in local mining circles during the past week by the announcement that the services of two or three directors of the Randfontein Estates Co. have been terminated. It was at first reported that all the directors had resigned, but this statement has been proved to be an exaggeration. The resignation of a portion of the Board is believed to signify a development of much importance and far reaching effect. For some time past it has been persistently rumored that another and more important firm has been acquiring a large interest in the Randfontein Estates Co., and it is stated (with what degree of truth I cannot at present say) that this firm is about to appoint its own representatives on the Board of the Randfontein Estates. The General Mining & Finance Corporation (more popularly known as 'Albus') announces that its subsidiaries earned a total profit of £61,069 from 136,159 tons milled during the month of April, as compared with £65,720 and 139,602 tons in March. The companies contributing to the April return were as follows:

Company.	Stamps.	Tube-mills.	Tons crushed.	Revenue.	Profit.
Aurora West	60	..	11,053	£12,730	£2,442
Cinderella Deep	80	2	15,000	22,569	5,034
Meyer & Charlton...	75	2	12,302	21,555	9,074
New Goch	120	3	27,845	32,151	12,146
Roodepoort United...	110	2	18,259	20,177	2,858
Van Ryn	135	6	31,400	47,409	24,805
West Rand Con.....	100	3	20,300	24,135	4,710

The General Mining & Finance Corporation has recently engaged in two schemes for the expansion of the company's operations. The more important of these is the acquisition of 1803 claims by the Cinderella Deep company. A new company is about to be formed, called the Cinderella Consolidated Mines, which will have a total claim area of 2092 claims and will thus be one of the three or four largest operating on the Witwatersrand. The authorized capital of this company will be £1,500,000, of which £1,159,450 will for the present be in issue. A central plant of the latest design will be erected on a suitable site and this will at first be of 100,000 tons per month capacity. The site for this plant will be so selected and the various units so arranged that the plant may easily be extended to treat 200,000 tons per month. Two new shafts are to be laid out with this in view. The technical adviser of the General Mining & Finance Corporation expects that the average profit per ton milled will be not less than 10 shillings. The present Cinderella Deep shaft is fully equipped and will serve the western portion of the property. The second or 'Central' shaft will be sunk on the old 'Rand Central'

claims, and the eastern section of the property will be served by a third shaft about 6000 ft. southeast of the Central shaft. The second important plan concerns the Roodepoort United Main Reef G. M. Co. (which now includes the Kimberley-Roodepoort mine). At this property a new reduction and treatment plant is being erected. One hundred stamps are to be installed on the back to back design. They will he 1900-lb. weight each, and will be operated by electricity. The stamps will be driven in sets of ten by separate motors. The stamp duty is expected to be about 12 tons per day at the commencement of operations, and this will eventually be raised to 18 tons or more. Five tube-mills (each 16 ft. 5 in. by 5 ft. 19 in.) are being installed, and a sand and slime plant of latest design is being put in. The whole equipment is laid out with a view to expansion, and the ultimate capacity will probably be in the neighborhood of 100,000 tons per month.

The mineral output of South Rhodesia for the month of March was £241,325. Gold mines, as usual, contribute the bulk of the return, the March yield being 54,277 oz., as compared with 48,442 oz. produced in the preceding month. The rest of the output is made up of contributions from coal, chrome iron, silver-lead, and copper mines. Recent developments in both the Matabeleland and Mashonaland have been of a highly satisfactory nature, and both in Johannesburg and London Rhodesian developments and new flotations are attracting as much attention as is the Rand. Perhaps a word of warning regarding new Rhodesian flotations will here be not out of place. A few years ago mining affairs in the British South Africa Co.'s dominions were stagnant and depression was most acute. Such a condition of things was brought about by gross over-capitalization of small rich quartz veins, the erection of machinery on these ventures regardless of potential value, and the utter neglect of development. Lately Rhodesia has, through sheer hard work, diligent prospecting, and more discriminating methods, come forward as a mineral State, and it would be a pity to see the country fall back into its old paths of depression through a repetition of the errors of fifteen years ago. That there are large auriferous formations in South Rhodesia has been conclusively proved by the discovery of the Shamva mine and the exploitation of the Eldorado, Giant, Globe & Phoenix, and Falcon mines. At the same time it must be remembered that many of the mines of the country are situated on rich quartz veins with no great length of ore-shoot, and to capitalize and equip such ventures on a 100-stamp basis before any exhaustive development has been done is bound to be highly prejudicial to the country.

MEXICO

Panuco.—Guadalupe de los Reyes. — San Fernando, Durango.—Real del Monte.

The Compañia Minera de Pánuco, one of the most important mining concerns of the State of Sinaloa, has just issued its annual report for 1909, the thirty-third year of its existence. This shows that the total revenue for the year was ₱884,182.53, and the total expenses ₱407,344.18, leaving a profit of ₱476,838.35. Out of this, dividends to the amount of ₱425,000 were paid. Since its organization the company has paid ₱7,465,000 in dividends. The Pánuco mines yield silver-gold ores, and are equipped with a 40-stamp mill, concentrating plant, and cyanide annex, the latter of late installation. Some ore assaying from 23 to 24 kg. silver and over 200 gm. gold per metric ton is shipped to the Selby smelter at San Francisco. The ore treated amounted to 13,411 tons, and this produced 15,325 kg. silver and 102 kg. gold. The treatment-cost per ton was ₱8.31, which is a much better showing than is made by several of the other big Sinaloa concerns, due to the fact that direct water-power is used for the operation of the mining and milling machinery. The Pánuca company is controlled by Spanish capitalists of Mazatlán, the men at the head being Genaro Garcia, Victor Patrón, and Juan Escutia. Recently negotiations were opened with Los Angeles men for the sale of the properties. The price asked is ₱6,000,000.

The Compañia Minera Guadalupe de los Reyes, another big Sinaloa producer, which is also controlled by Spanish interests of Mazatlán, failed to make as good a showing as usual last year. The production amounted to ₱1,427,000, but the expenses were high, and dividends of only ₱290,000 were paid. The company has paid as high as ₱1,000,000 in annual dividends, but for several years the distribution has been less. The concern has a power problem to solve, as adjacent fuel supplies are giving out, and plans are now being considered for the installation of charcoal gas-engines at a point where an abundance of charcoal can be had, and the generation and transmission of electric energy to the mines and reduction plant. Luis Basave, a young mining engineer, is in charge of the company's affairs. J. S. Johnston, of Los Angeles, California, representing a group of Los Angeles men, has just purchased the properties of the Metates Mining Co., in the State of Sinaloa, two days by road and trail from Mazatlán. Maximiliano Lopez Portillo was the principal owner. The price is $125,000 gold, and a payment of $31,000 has been made.

The San Fernando mine in the municipality of Juarez, State of Durango, which was abandoned by the Fernando Mining Co., a Calumet & Hecla concern, a few years ago, is now under option to American interests for ₱800,000. When the Boston men abandoned the properties they are reported to have turned over the titles as gifts to John T. Canfield, an American resident of Culiacán, the Sinaloa capital, and

San Rafael Mill, Pachuca.

a former employee of the company. He has given an option to Los Angeles men, who in turn are dealing with New York parties. The mines were purchased fourteen years ago by Alexander Agassiz and associates on the strength of a report by James E. Mills. The Fernando Mining Co. was organized to carry out extensive development and milling plans. Several shafts were put down on the Fortuna, a big gold-copper vein, and fully $1,000,000 gold was spent in the erection of a mill, concentrating plant, and smelter, the installation of a hydro-electric plant, and the construction of six miles of electric railroad. At a depth of 600 ft. the profitable ore gave out, and the company's engineers reached the conclusion that the mine was bottomed. As a result it was decided to abandon the enterprise, and Mr. Canfield was given a commission to remove and sell the machinery and supplies on hand. At a cost of ₱35,000 he had the mining, milling, and electrical equipment freighted to Culiacán, and since that time he has realized about ₱90,000 from sales. The greater part of the equipment is still in his hands. Mr. Canfield is working the Tocaila, a gold vein on which some work was done by the Fernando Mining Co., and is treating a small amount of ore in arrastres. During the period of its operation the old company took out ore worth ₱7,000,000, and since the abandonment of the mines several engineers have reported favorably on the possibilities of further development. The surface holdings consist of 197 pertenencias (486.59 acres).

The old Rosario mine of the Real del Monte y Pachuca company, which gave the great bonanza that was opened just after the transfer of the properties from English to Mexican interests, is to be again worked on an extensive scale. Electric hoists have been ordered, and development will be with a view to a production of from 200 to 300 tons per day. The present American company, which is controlled by the U. S. Smelting, Refining & Mining Co., is

planning a number of extensions, and will enlarge its Guerrero and Loreto reduction plants. The production of the Real del Monte y Pachuca mines in 1909 was 213,630 tons of milling ore and 1579 tons of shipping ore.

BUTTE, MONTANA

Georgetown District, Southern Cross, and Oro Fino. — Ophir.— Washoe Smelter.—Butte & Superior.—Keating.

The Georgetown district, which gives promise of being one of the richest gold camps ever located, is now receiving attention. It is but a short distance from Anaconda. The mine attracting most attention at present is the Southern Cross. Experts representing the A. S. & R. Co. have visited the property for the purpose of making an examination. The shaft is now down 326 ft., and there are three station levels. Samples show that more than 300,000 tons of ore are in sight and will assay about $15 in gold. The Southern Cross was discovered by Lucien Eaves when he was taking out a wagon load of ore from a neighboring property. A snowstorm had raised the road so that his team could not get under a trestle and he had to lower the road. In doing so he cut an immense body of gold ore. With the proceeds he constructed a mill, put the property in good shape, and had enough left to become independent. The story of the discovery of the Oro Fino claim, a few hundred feet east of the Southern Cross, is also interesting. Charles Bostrom two years ago was a barber in Anaconda and after making a study of mining from books, decided to go to the Georgetown district and work in the Southern Cross. While there he spent his spare time in prospecting and soon decided to secure a lease on the claim known as the Oro Fino. He engaged the services of an old time prospector and the pair started to work on shares. Almost from the start the claim has more than paid for the work done. The owners found one body of ore which ran as high as $1000 to the ton. While the one time barber is decidedly adverse to talking about his business, it is quite well known that during the past 12 months he has taken out more than $100,000 and recently he opened an orebody more than 35 ft. wide of a much higher grade than is found in the Southern Cross.

The Ophir mine of the Butte Central Copper Co. should be in operation by the last of the present month. It was not anticipated that the work would be completed before the middle of July, but all calculations have been upset by rapid work. The extent to which the Butte mines are being worked at the present time may be imagined from the fact that the Washoe smelter at Anaconda is receiving from 11,000 to 11,300 tons of ore daily. Inasmuch as the supposed capacity of the smelter is but 10,000 tons daily, it will be seen that the Anaconda plant is being crowded to its utmost capacity. Since the merger the position of manager of mines has been abolished and now the properties are in charge of superintendents grouped in much the same way as under the old management. This policy not only abolishes an office and saves money, but it places the various superintendents more directly in a position to handle the mines as they desire without having to consult with managers. The Butte & Superior company is still keeping up its shipments of ore to the Basin concentrator. Those who have been down in the mine unhesitatingly assert that there is ore sufficient to allow shipping to continue for five years at double the present output, and further that the ore is high-grade. Many wonder why things are not running along more smoothly and why the new concentrator, which was started some time ago, is not being pushed to completion. As yet nothing is definitely known whether the minority holders of the Parrot are to push their suit for an appraisement of the stock, but to make sure that everything will be safe guarded so far as the company is concerned, the Parrot special meeting which had been adjourned until June 7 has been further adjourned until June 21, by which time the protestants will have appeared in court and made their formal demand for the appraisement if they propose carrying out the notice served on the company. The Keating Gold Mining Co., in the Radersburg district, is now in charge of R. G. Goodell, of Duluth, who takes the place of Jesse B. Roote, who has been at the head of the company. At the annual meeting held in this city a few days ago it is stated that the men from Duluth who are heavy stockholders expressed dissatisfaction with the way matters were being conducted and decided to take the affairs of the company into their own hands, so they not only elected a president, but a vice-president and secretary-treasurer from their own ranks. The directors elected were: R. G. Goodell, A. G. Agatin, J. H. Barnes, Charles Newton, and Jesse B. Roote. The latter is the only real Butte man on the board as the three first named are Duluth men, and Mr. Newton, while residing in Butte at present in his capacity as superintendent of the Butte-Ballaklava, is from Duluth. Mr. Agatin is vice-president and Mr. Barnes is secretary-treasurer. No report was submitted at the meeting so far as the public knows, but one of the officers stated afterward that the property had just been fully equipped with electricity, and that the first shipment of ten cars of ore had been made to the Pittsmont smelter in this city. It is intended to continue for the present weekly shipments of ten carloads of ore. In order that an office may be maintained in this city an assistant secretary, A. C. McDaniels, has been appointed.

SALT LAKE, UTAH

International Report. — Ohio Copper. — Bingham Shipments.— Tintic News.—Boston Sunshine Closes.

The completion of the temporary line of the San Pedro, Los Angeles & Salt Lake railway will mean much to Salt Lake and the mining industry. The branch road to Ploche will be repaired in a few days, allowing all-rail communication with that camp, and the Los Vegas & Tonopah road can be reached from this city, besides a number of smaller districts that have been cut off by the washout, which was the most disastrous in the history of railroading. The first annual report of the International S. & R. Co., covering the year 1909, shows income of $2,586,543, expenses of $1,450,830, dividends of $300,000, and surplus of $935,000. During the year the company expended $1,578,628 in the construction of the Tooele smelter, which is expected to be ready for operation by August 1. About 15,000 tons of ore will be stored during July, so that, once started, the plant may have an uninterrupted run. The report states that favorable results are expected from the operations during the last half of the year, but owing to the difficulties which always attend the starting of a new plant the manager does not make any prophecies as to earnings. J. B. Risque, for the past three years general manager of the Utah Con., has tendered his resignation, to take effect September 1. Mr. Risque has many private interests to which, as well as consulting work, he will devote his time. The Centennial Eureka has declared a dividend of $3 per share, the first since 1908, bringing the total to $24 since the company passed into the hands of the United States S. R. & M. Co. This company owns all but 136 of the 100,000 shares of capital stock. The annual election of the Ohio Copper Co. resulted in returning all of the old directors except Russell Hopkins, who resigned recently. The report of the first quarter shows receipts of $112,972 and expenditures of $91,302, leaving a net profit of $21,670 for the quarter. As there has been no construction carried on during the quarter covered by the report, it is assumed that the expenses were wholly for operation, which does not tally with the newspaper statements that the company has been earning $1000 per day since the mill went into commission. At a special meeting of the Con. Mercur, George E. Airis was elected a director to succeed his father, the late E. H. Airis. Resolutions of respect were adopted for Mr. Airis, who has been a director of the company since its organization and was secretary of the predecessor, the Mercur Gold Mining Co. Colorado, once one of the strongest stocks on the local exchange, is selling at the lowest price since 1907. No definite reason can be assigned, but it is generally supposed that the single orebody that has furnished all of the ore has been exhausted and the future of the mine is in doubt until it has been prospected at depth.

The month of May was the largest in point of tonnage that Bingham has had. The official figures are not yet avail-

able, but they are known to be in excess of previous records, and the production for the month will be 8,000,000 to 9,000,000 lb. In one day recently 402 carloads were shipped, Utah Copper alone sending out 378. The work of making the changes which are expected to increase the capacity of the Utah Copper plants is going on steadily, the new machinery being all in, in three of the units of the Magna mill. It is generally supposed that the delay in the financing of the Ohio Copper Co. necessary to enable it to finish its mill is due to the fact that as yet no satisfactory contract has been made for the use of the Mascotte tunnel. This tunnel is the property of F. Augustus Heinze, and the company has only a short-time contract for its use. The proposed backers are loath to put up the money unless a long-time contract can be made for the use of the tunnel, as without it the Ohio would be at heavy expense in the matter of shipping ore, and Mr. Heinze seems to hesitate about entering into a contract covering any length of time. The tunnel of the Bingham Metals Co. is now in 3400 ft., and a vein of milling ore has been opened. This vein has been penetrated for 70 ft. without encountering the opposite wall and proves the mineralization of the west side of the mountain. The company will make no effort to develop any of the ore except by leasing until the tunnel has been entirely completed. Work has been resumed in the Bingham Copper property in which the North Utah recently bought an interest. Rumors of a discovery sent the stock up on the local exchange, but the management positively denies that any ore has been found except a body of milling grade which was opened before the old management ceased operations. The Utah Mines Coalition has filed suit against the City Rocks Mining Co., claiming illegal extraction of ore to the amount of $500,000, which, according to the Utah laws, renders them liable for three times that amount. A court order permitting the complainant to make a survey of the defendant's property is asked. The Carbonate, which was recently taken over by New Yorkers, is about to commence shipments, the mine having about 4000 tons of shipping ore blocked when the transfer was made.

The Grand Central at Tintic is now shipping somewhat more than a carload per day, recent developments having opened orebodies both east and west of the shaft. The directors of the May Day have levied an assessment of 2c. which will be delinquent July 15. The money will be used to install equipment which can be used at greater depth than that at present in place, and the shaft will be pushed to the 1000-ft. level with the hope that the ore may be found with depth. The assessment has been delayed, as 400,000 shares of May Day are held by the Uncle Sam and the officers of the two companies are very much the same. The Uncle Sam did not wish to stand the expense out of its treasury, so has distributed the May Day stock as a dividend, on the basis of eight shares of May Day for ten of Uncle Sam. The Uncle Sam has also declared a cash dividend of 2c. per share, which will a little more than offset the May Day assessment. The Eagle and Blue Bell has opened a new orebody within 250 ft. of the shaft that is being sent down to the lowest levels as the main opening of the mine. The new ore nets about $12 to $25 per ton. Under present conditions the ore must be trammed about half a mile to get it out, so it will be seen that the sinking of the new shaft will be a wise move.

The Boston Sunshine has been closed and the final clean-up of the mill is being made. When the property was purchased fourteen months ago there was a year's supply of ore in sight, but extensive prospecting has failed to develop any more, and the management decided it was advisable to shut down before any further loss. The stock was floated at 30c. per share and the stockholders will receive, with the proceeds of the clean-up, 13c. per share. The mill has been a great success and the news of the shut-down has occasioned considerable surprise. In Beaver county the Hub has opened a 42-ft. body of ore that will average $26 per ton, with an excess of copper over silica of 20%. The principal content of the ore is copper. The Utah Gold & Copper Co. has commenced work on its concentrating mill and a new hoist. The hoist is to be for an incline raised from the tunnel to the surface on the vein. The mill is to have a capacity of 100 tons per day.

Utah Copper Mill, Garfield, Utah.

NEW YORK

Railway Injunction. — Copper Production. — Mexican Notes.— Canadian Mines. - Utah Copper Bonds.—Phelps-Dodge.—Granby.

The injunction obtained by the Federal Department of Justice restraining some twenty-five Western railroads from charging increased freight rates, and the later conference between the railroad officials and Mr. Taft and his cabinet, have formed a chain of events sufficiently important to keep our financial centres in anxious expectancy. The market has been swamped with selling orders; and it was said that "Wall Street is making the market an object lesson." When the outcome of the Washington conference is analyzed, however, there is really little to substantiate this theory. The railroads have yielded gracefully and completely, but in so doing have absolved themselves from responsibility. The real question now is not corporate regulation, but the competency of the present governmental authorities to regulate wisely.

The copper situation has perforce been adversely affected. The most disappointing feature of the statement of the Producers' Association for May is the dwindling of the domestic demand which absorbed 59,305,222 lb., the lightest consumption since last September, and a decrease of 8,680,000 as compared with April. Transportation companies being among the largest users of copper, any condition causing cancellation of construction contracts and the holding up of work on extensions and replacements would be directly felt at once in the metal market. Deliveries abroad show some improvement. Exports increased 14,-

163,037, and amounted to 45,495,440 lb. The production for May was 123,242,476 lb., an increase over April of 5,764,837, a greater production than any month since October last. The increase in the surplus was 18,441,814 lb., while the total on June 1 was 160,425,973; European stocks on hand are estimated at 239,142,400, giving a world's visible supply of practically 400,000,000 lb. of copper. The decrease in the European visible supply has been offset by the increase in American surplus and the present conditions emphasize the statement made a few weeks ago by the management of the Rio Tinto of Spain, that the control of the copper situation lay with the low-grade, low-cost producers of the United States. Curtailment is the remedy, but some of the principal factors are evidently marshaling forces for a battle for supremacy. On the one hand is the new smelter at Tooele, just being completed, backed by the International. It is to handle the ores of the Utah Consolidated, the Giroux, and any other Cole-Ryan properties within its territory. This side of the line of battle includes the Cole-Ryan coterie, with Amalgamated-Anaconda, Standard Oil affiliations, including the Lewisohns and the United Metal Selling Co. Against these are arrayed Utah Copper, Nevada Con., Ray Con., and the A. S. & R. Co., with the Guggenheim-J. P. Morgan alliance in the circles of high finance. On both sides there is the evident determination to dominate in the smelting and refining industry. It may be taken for granted that both know their allies; the Lake mines and the Phelps-Dodge properties are huge factors in copper, and where such weight is to be thrown in case of struggle is undoubtedly already known. The situation is a most interesting one, but by no means encouraging for the red metal market.

A short time ago, when a story of a break in the ranks of the Copper Producers' Association first appeared, there came to light about the same time a story to the effect that the Tanganyika Concessions, Ltd., a British company operating in the Congo Free State under a charter obtained from the late King Leopold, had an accumulated surplus of 200,000,000 lb. of copper ready to be thrown upon the market at any time its absorption could be deemed possible. Investigation now shows that this story was evidently circulated purely for market effect. 'Tanks', as the company is known on the London Stock Exchange, is developing a copper production of some considerable importance from three mines. The Star of the Congo is said to have large reserves of ore blocked and to have a mineralized deposit of 4000 ft. in length and some 500 ft. in width, the main vein portion being some 28 ft. in width and running 14 to 18% copper. The second property in magnitude is the Kambove, the third is the Kansanshi, which is producing in a small way. The properties are being connected by rail and in the course of two or three years are expected to output five to seven million pounds of copper per month.

One of the most active of the development companies in New York at present is the Proprietary Mines Company of America. It is building a 250-ton cyanide mill at the Tajo de Dolores mine at Guanajuato, Mexico, sinking a deep shaft on the dip of the ore-shoot of the famous old Valenciana mine at Guanajuato, and re-opening the Yellow Jacket Gold mine in Idaho. The Tajo mill will be completed by November 1; it is being equipped with Schmidt tube-mills and Sweetland filter-presses. The machinery has all been purchased. The Nueva Luz shaft was 1890 ft. deep on June 3, and will go to 1966 ft. (600 metres) before a cross-cut is run out to the Veta Madre. This cross-cut is to be begun before August 1; the sinking of the shaft is subsidized by the Mexican National Government. At the Yellow Jacket, John B. Hastings is in charge of the work of overhauling the mill and re-opening the mine.

Aside from the coppers the mining markets are very quiet. The distribution of a 5% interim dividend by the Nipissing Mines Co. is of some encouragement to the holders of Cobalt shares. The showing made by the Goldfield Con. is turning the attention of the mining investors to this issue, and the comparisons between the dividend returns on these shares and those of some of the leading coppers are beginning to tell in favor of the precious metal mines. Porcupine remains something of a riddle, some eminent engineers having recently visited the district and reported most unfavorably. Other visitors have returned filled with enthusiasm. Some of the figures at which claims are reported to have changed hands recently would presage a boom, but as yet there has not been enough development to really prove any of the territory. The Utah Copper Co. is considering a $2,500,000 bond issue, to finance the railroad which is to connect the mines at Bingham with the smelter at Garfield. At present the ore is handled by the Denver & Rio Grande, and is carried 27 miles; the company's engineers are expecting to approve a new route of 17 miles. The new bond issue is to be secured by a first lien upon the railroad, and, while definite announcement has not been made as yet, it is expected that the bonds will be offered at par and will carry some attractive privilege of conversion into stock. Utah Copper has a cash balance of some five and a half millions on hand, and at the moment is an important factor in Wall Street loans. It is barely possible that the two and a half millions necessary for the road may be taken from the cash surplus. Phelps, Dodge & Co., Inc., is paying its regular quarterly dividend of $250 per share. This concern has been recently credited in some quarters with an ambition for a more dominant position among copper producers, the theory being that by building a railroad from its smelters to the Pacific, Phelps-Dodge ores and matte could be sent to the Isthmus of Tehuantepec, thence across east by water to the Perth Amboy refineries, so cheaply that the company would have the lowest cost copper on the Atlantic seaboard, and so absolutely dominate the copper market. The price paid to W. A. Clarke by the Amalgamated is still unknown, and as Amalgamated holds a rather precarious position at the moment the question is of some importance. Amalgamated pays $2 per year and sells at a price which could only be justified by highly speculative possibilities, or the possession of a large surplus, neither of which Amalgamated can be said to possess. There is much analyzing of the reports of Amalgamated and Anaconda, but the ratio of return remains the same, and while Amalgamated holds a recognized place as a speculative issue it is weak under present conditions. The rehabilitation of the Granby Consolidated seems to have been indefinitely postponed. When the report of Otto Sussman was made last April, the collapse followed and the public and the shareholders were asked to suspend judgment until another report could be had, and the conditions thoroughly investigated. Jay P. Graves, vice-president of the company, recently submitted a report made after a detailed investigation; since which the board of directors has held two meetings, without giving out any information as to Mr. Graves' findings, and the inference is that the directors think it best to keep the report secret. The disappointing surprises in Granby and in North Butte are unanswerable arguments in behalf of systematic mine reports and publicity in regard to mine conditions. The new Federal Bureau of Mines just established, which is to be headed probably either by J. A. Holmes, of the Technologic Division of the Geological Survey, or by Edward W. Parker, also of the Geological Survey, being chief of the Department of Mineral Resources, can, if given legal authority, accomplish much toward the upbuilding of the mining industry by work along this line. The California-Nevada Copper Co., headed by F. L. Underwood, formerly of the British Columbia Copper Co., has arranged for the erection of a 200-stamp mill on its Ebner property near the Treadwell mine in Alaska. The property is a large milling proposition of the same class as the Alaska Treadwell, the Alaska Mexican, and the Alaska Perseverance. The present stamp-mill is to be built as the first unit of a larger plant. The engineers estimate a potential earning capacity for the mine, when fully equipped, of more than three quarters of a million annual net profit. A party of New York engineers and capitalists have left New York to visit the properties of the Radersburg Consolidated Mining Co. in Montana. The trip is to include visits to the Ohio-Keating mine at Radersburg. At Placerville, Montana, the Manhattan California mine is to be inspected, and from there the party will go to Elk City, Idaho, where another property controlled by the same people is situated. W. Murdoch

Wiley and R. B. Lamb, the latter being formerly connected with the Marcus Daly mines at Butte, Lawrence B. Adams and B. Binnard are of the party.

ELY, NEVADA

Nevada Con. Reduces Output.—Giroux Cuts Station.—Tungsten Mill.—Ely Tonopah Railroad.

During the past two weeks the Nevada Consolidated has shown a disposition to reduce its output of copper. It has recently adopted a policy of having one section of its concentrator closed for repairs all of the time, and now two are down the greater portion of the time. As there is no shortage of ore, this is taken to mean that the company is not anxious for a large output during the present era of low prices. The company's output for last month was five and a half million pounds, but from present indications it will not reach five million pounds for June. Several thousand tons of ore per day in excess of the capacity of the concentrator could be produced by two steam-shovels operating on ore. At the present time only one shovel is working on ore, and it is easily supplying about 7000 tons per day. Four steam-shovels and seven churn-drills are at work in removing the overburden from all sides of the Copper Pit. A railroad track has been laid to the Liberty claim a half mile west of Copper Pit, where another steam-shovel mine will be opened during the present summer. Three steam-shovels are now on the road from the East which will be put to work there as soon as they arrive. The sulphides come near to the surface in that locality, in fact it is stated that the overburden will not exceed 60 ft. The cutting of a pumping station 20 by 40 by 125 ft. in solid limestone on the 1200-ft. level of the Giroux was finished June 12, and as soon as the large chamber can be cemented, two pumps of a capacity of 600 and 1200 gallons per minute will be installed, after which the cross-cut will be started to connect with the lower levels of the Alpha shaft, where a large tonnage of high-grade smelting ore has been developed. Steel structural material for the head-frame for the big shaft has arrived, and will soon be put in place. Excavating for the foundations for the engines and boilers for the permanent hoisting plant is proceeding rapidly and will be completed within six weeks. Eight of the boilers have arrived and parts of the engine are now coming in. Thomas F. Cole, president of the company, will arrive in a few days, when it is expected that orders will be issued to commence the sinking of a permanent working shaft on the Rickard Ely ground, recently purchased by the company, which will be the same in dimensions as the Giroux shaft, 12 by 19 ft. It is also expected that concentrating plant of 500 tons capacity will soon go into commission. Dr. Nehrbas, L. C. Hendrickson, and Theodore Burkhart, of Portland, Oregon, who are officers of the Kohinur M. & M. Co., operating properties at Piermont, arrived from the mines today, and state that the company has in contemplation the installation of a 10-stamp mill during the present year. Lane C. Gilliam, a mining engineer of Los Angeles, has just finished an examination of the property, and his report was highly satisfactory to the officers of the company. E. L. Fletcher, manager of the Tungsten properties, forty miles east of Ely, has just returned from Denver, where he purchased a complete concentrating plant which will be installed on the property within the next four months. The plant comprises a battery of Nissen stamps and necessary jigs. The company already has its boilers and engines installed. About twenty-five men have been employed in developing the property for the past year, and will soon largely increase the force. O. W. Turner, who promoted the Butler mines of Tonopah, is president of the company. From general report it now seems definitely settled that construction work will soon commence on the Ely Tonopah railroad, which will be a connecting link between the Western Pacific at Shafter on the Nevada Northern and the Tonopah & Tidewater railroad at Goldfield. A permanent survey for the road was made last year by way of Currant creek, but it now seems probable that the route will be changed to one by way of Hamilton, from near which point a branch will be extended into Eureka. This town has been cut off from railroad communication since the washing away of the Palisade & Eureka railroad in March. The principal mines of Eureka are owned by the United States Smelting Co. of Salt Lake, and from them it drew from two to three hundred tons of ore per day. It is said that the company is much in need of the ores, which are used as a fluxing base. It is probable that the road will run from Hamilton to Cherry creek on the Nevada Northern, fifty miles north of Ely, which would give it almost a direct line between Goldfield and the Western Pacific at Shafter. This would be a more direct line than the one heretofore surveyed through Ely. All of the machinery for the 10-stamp mill under construction by the Amalgamated Nevada Mining Co. has arrived at San Pedro, and the heavy timbers for the plant are being cut in the mountains near by. It is expected that the plant will be erected and in operation some time during the coming fall. It will treat custom ores. A 3-ft. vein of $50 ore has been uncovered on the Ely Calumet property by lessees. It is understood that Thomas F. Cole has an option on a majority of the stock of the company. The Eureka shaft of the Ely Central has reached a depth of 515 ft., while the Clipper shaft is down 230 ft. The work is progressing steadily.

WASHINGTON, D. C.

Land Withdrawal Bills in Senate and House.

The bill permitting the President to withdraw from public entry any of the undisposed of public lands is having a most difficult time in the Senate. This is the bill that passed the House several weeks ago and which was so objectionable to the oil men of California. It has been amended in the Senate to suit the ideas of the oil men, but still does not seem to be satisfactory to a number of Western Senators. There is really a three-cornered fight on over the measure. Some Senators believe that the President now has the right to withdraw the public lands from entry. Others, mainly from the West, are against the legislation on the theory that it would confer altogether too much power in the President. Still others are of the opinion that it is a wise measure and should pass. W. B. Heyburn is decidedly against this administration measure. After denouncing the bill in scathing terms, he sarcastically remarked that the people of the East get their ideas of the West from the romance writers with whom 'Long-Haired Dick' or 'Six-Shooter Joe' were of more consequence than the men who opened mines and built up the agriculture of the region. C. D. Clark, of Wyoming, declared that the bill placed absolutely in the hands of the President the disposition of practically every acre of public land. "That," said he, "is not a safe proposition in a Republican form of government. I am unwilling to place in the hands of any man, I care not how virtuous he may be, the power to deal with hundreds of millions of acres of land as he may see fit." Mr. Clark offered an amendment to the effect that if Congress failed to take affirmative action upon the report of the President withdrawing lands at the same session in which the report is made, the withdrawals should be inoperative and the lands should be restored to the public domain and be subject to sale and entry under the general land laws. The amendment was defeated, after Knute Nelson, Senator from Minnesota, had made the statement that it would be utterly destructive of the entire bill. "It would repeal a power that now exists in the President," said Mr. Nelson. "There are some withdrawals which I have no doubt all men will agree the President can make, and under existing law such withdrawals remain in force until revoked by the Executive or by act of Congress. This amendment revolutionizes all that." The Senators got into such a tangle over the bill that they laid it aside for a future hearing, but was passed without amendment June 15. Gifford Pinchot issued a statement as to what he believed to be a joker in this bill. He declared that it contains one wholly indefensible provision. Section 2 provides that if minerals other than coal, oil, gas, or phosphate can be found on any land withdrawn for public uses, the land shall be open to private appropriation. Mr. Pinchot says that section, if passed, will operate directly for the benefit of the water-power interests and directly against the interests of the people.

General Mining News

ALASKA

(Special Correspondence).—The Northland Development Co. is operating near Big Harbor and expects to have a cargo of high-grade ore ready for shipment before fall.——Sinking on the Goodroe property is progressing with favorable results. Rich bornite with some gold and silver is being developed. Returns from the last 400 tons shipped to the Tyee smelter are said to be very satisfactory to the owners.——The Mount Andrew, It, and Sulzer mines are steadily shipping and blocking out large quantities of ore. ——Over 20 different prospects are being developed in this district, most of them with encouraging results.

Ketchikan, June 4.

ARIZONA

COCHISE COUNTY

The recent survey of the Holbrook shaft at the Copper Queen showed it to be three feet out of line between the 300-ft. level and the surface. Arrangements have been made to stop work at this point till the shaft can be retimbered from this level to the surface. During the temporary shutdown the Czar and Spray shafts will be used as a traveling way and for the handling of timbers. The company has installed two new storage battery motors for hauling in the mine.——Preparations have been made at the Denn-Arizona Copper Co.'s property to resume sinking. One of the heavy pumps has been placed on the south station of the 1350-ft. level and room for an additional pump has been cut on the north side. The ore recently opened by the drift toward the Briggs on the 1350-ft. level has averaged 9% copper.——Development has been stopped temporarily at the Bisbee Extension while changes in the power-plant are made to permit the using of oil for fuel instead of coal. New pumps are being placed in the mine and new water and steam columns in the shaft.——Three Prescott sinking pumps have been installed in the Tombstone Consolidated below the 800-ft. level.

GILA COUNTY

(Special Correspondence).—The Venture Exploration Co., a syndicate of Duluth capitalists headed by W. A. Eaton, president of the Cactus Copper Co., is to acquire 70% of the stock of the Gibson Copper Co., whose property, consisting of 15 claims 18 miles west of Globe, has produced over $1,250,000 worth of high-grade copper sulphide in the past six years. The option on 70% of the stock is for $400,000, the payments being distributed over four years. Plans for development and installation of concentrating equipment are being made.——Grading is under way at the Inspiration for an experimental mill capable of treating 75 tons of ore per day. The plant will be completed in two months.——The Miami Copper Co. will establish its own medical and surgical department beginning July 1. Plans for a new and fully equipped infirmary are being prepared.——Driving westward for 150 ft. on the 660-ft. level of the National Mining Exploration Co.'s Williams shaft has developed an ore-stringer 36 in. wide. Samples taken across the vein show the copper content to be 30%. The copper occurs as both carbonate and glance. H. W. Woodward is superintendent. ——The cross-cut being driven to open the Old Dominion vein on the 500-ft. level of the Telfair shaft on the Arizona-Michigan property is 963 ft. long. The vein is estimated to be 137 ft. from the face of the cross-cut.——Churn-drill hole No. 6 on the Live Oak property has struck disseminated ore 250 ft. from the surface.

Globe, June 11.

GRAHAM COUNTY

The Gold Belt Consolidated Mining Co. has stopped operations on its property ten miles from Clifton. A mill has been installed on the claims by the stockholders who are largely local operators.

MOHAVE COUNTY

Four feet of high-grade shipping ore and nine feet of milling ore have been cut on the 150-ft. level in the old Keystone mine at Mineral Park. The ore is rich in native and ruby silver, and assays made from samples of the 100 tons already broken, run from $250 to $2400 per ton. The Keystone, owned by Tom McNeely and James Uncapher, of Mineral Park, was bonded last December by S. R. Porter, of Los Angeles, who re-opened it after it had lain idle thirty-five years. There is about 25,000 tons of ore in the old stopes that will be shipped to the Needles plant.——The C. O. D. mine, whose history is similar to that of the Keystone, made its first shipment since operations were resumed there several months ago. It is expected that the ore just shipped, about 30 tons, will net over $6000. The second station has been cut in the new shaft and another level started.——The Gold Road and Tom Reed mines, at Goldroad, shipped gold bullion to Kingman a few days ago valued at $55,000, representing about a two weeks' run of the mills. The automatic-pouring furnaces installed at both plants a few weeks ago are proving very satisfactory. A good body of milling ore was cut recently on the east 700-ft. level, about 100 ft. from the shaft in the Gold Road mine.

PIMA COUNTY

A good body of ore is being opened in the Trece de Mayo mine in the Patagonia mountains by the owners, A. L. Peck and J. Saldamando. The shaft is down 150 ft. on the vein which is about 6 ft. wide with an 18-in. pay-shoot.——The Mansfield Mining Co. is reported to have cut a rich shoot of copper-gold ore in the Black mine.

YAVAPAI COUNTY

The 2-stamp mill at the Monte Carlo property is being run on ore that averages $50 per ton, the mill crushing about 1200 lb. per day.——At the Commercial Mining Co. group, in Copper basin, 12 miles west of Prescott, the shaft is down 140 ft. in ore. There are several other bodies of ore that the shaft will open at depth for the mineralized zone is from 300 to 600 ft. wide.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence).—The Dane-Mitchell Mining Co., which recently purchased the Dane and Mitchell groups near Pine Grove, has installed a 25-drill, two-stage, Sullivan air-compressor, the power for which is furnished by a 5-ft. Pelton wheel. Water is obtained under a 255-ft. head from the Volcano Mining & Ditch Co., at the rate of 12½c. per miners inch per day. There was a light 10-stamp mill on the property when the company acquired the ground but this has been torn down and a new one erected to which the company will probably add more stamps in the near future. The mill is also driven by water power. The vein has been opened to a depth of 200 ft. by two levels, one driven from the 135 the other from the 200-ft. station in the shaft. The vein dips 45° toward the east and is about 20 ft. in width, the shoot assaying from $1 to $10 per ton. The company plans eventually to sink a new shaft in the foot-wall and keep the drifts parallel to the vein. The chutes will then be driven to the vein every 30 or 40 ft., and the ore worked by the shrinkage system. Edwin A. O'Donnell is manager. ——The Craymer Brothers, who sold the Mitchell property, have secured a lease on the Reward mine in the same district and erected a 2-stamp mill to test the ore. A shoot over 100 ft. long has been opened, portions of which will plate as high as $50 per ton.——The Little Climax mine, between Pine Grove and Jackson, has been examined in the interest of F. A. Stokes, and it is probable that operations will be resumed on the property which has been idle for some time on account of the death of one of the owners.—— The Ferry Brothers are sinking an incline shaft at their property near Volcano and expect to tap the channel this season.——Several men have been put to work at the Lincoln mine, near Sutter Creek, and the property will be unwatered and thoroughly prospected. The property has produced considerable good ore in the past, but lost the shoot and was shut down. Later it was re-opened and over $150,000 is reported to have been spent in trying to find the ore without success. The work in the adjoining properties has led the present operators to believe that the previous management followed the wrong direction and a strong effort is to be made to recover the shoot.——The South Eureka is to shut down temporarily for a few months while

a new head-frame and electric hoist are installed. The shaft will be aligned and retimbered where necessary.

Jackson, June 13.

MODOC COUNTY

The 50-ton custom mill which is being erected in the Hoag mining district will be completed by July 1, when it will commence work on custom ores. The mill will be under the supervision of J. T. Wall. The Hoag district has produced considerable rich ore in the past few years but has been held back by lack of milling facilities. The east drift of the Consolidated, on the Mountain View claim, has opened three feet of ore, and the Big Four which is under lease to Bashler, Brown & Treudt, has blocked out a considerable tonnage ready for stoping.

NEVADA COUNTY

A shoot of high-grade ore has been opened in the Red Ledge mine near Washington.——Work has been started on the re-opening of the Wisconsin mine, at Graniteville, which has been idle for the past 40 years. The shaft, which is down 110 ft., is being cleaned out and retimbered, and arrangements have been made for the installation of additional machinery. Fred Medlin is superintendent.——Ore has been opened by both north and south drifts on the 1100-ft. level of the Pittsburg mine, between Nevada City and Grass Valley, showing the shoots to be from 16 to 18 in. wide.

PLUMAS COUNTY

The buildings near the shaft of the '76' mine of the Plumas Eureka Mining Co. were destroyed a few days ago by fire, resulting in the loss of several thousand dollars. A

Bully Hill Smelter.

portion of the aerial tramway was destroyed, though the timbers of the shaft and the hoist were but little hurt. Julian McCarty Little is superintendent of the property. ——There are 15 men working in the Del Monte mine, near Seneca, which was recently bonded to J. J. Reilley.——C. L. Burt and S. A. Bretherton have secured a bond on the Salmon Falls placer mine on the north fork of the Feather river. The group covers one of the ancient river channels and is owned by G. H. Goodhue and associates.——Harry Merrill, who has a lease on the Dutch Hill gravel mine, one of the old time producers, is driving an incline to tap the channel.——Considerable work is being done on the properties in the Portola district. Arrangements have been made to ship four or five tons of ore from the Miller claims to the smelter, and the shaft on the Brooklin is down 50 ft. with cross-cuts started to the vein.——Joseph Young and H. J. Langhorst are preparing to commence work on the claim on Poplar creek which they bonded recently from O. W. Wall.

SHASTA COUNTY

The French Gulch Mining Co., which owns the Milkmaid mine at French Gulch, has secured a two years' bond on the Sibyl group and will commence the exploration of the property.——Lessees at the Green mine are driving on a vein that varies from a few inches to 3 ft. in width.——At the Centennial the lessees are opening a 4-ft. vein.——J. B. Keating, manager for the Bully Hill company which operates the smelter at Kennett, is authority for the statement that the company will not build a bag-house. No attempt will be made to resist the Government if the officials of the Forest Service insist that the plant close down or install some smoke-consuming devise.——The machinery for the Nissen mill which the Victor Mining & Power Co. is to erect at its property in Harrison gulch has been shipped from Red Bluff, and it is thought that the plant will be in operation by August.

SIERRA COUNTY

(Special Correspondence).—The lower adit has cut the vein at the Tightner mine, about 1700 ft. from the portal, and at a depth of 640 ft. below the upper workings. At the point of intersection six feet of high-grade ore is disclosed. The driving of this adit has been in progress about five years, the hard formation and use of hand drills explaining the slow work. H. L. Johnson is the owner of the property.——The winze at the Sixteen-to-One is expected to cut the vein at an early date.——Within a few days the Middle Yuba Hydro-Electric Co. expects to commence the placing of poles for its transmission line to Alleghany, to supply the town and mines with light and power. E. H. Steels is in charge of the work.——The Rio Antigua Mining Co. is developing the recently opened Bald mountain channel in the South Yuba mine at Forest. F. H. Kuhfeld is manager.—— A shoot of rich ore has been opened in the Lee mine, situated in Ladies canyon, three miles from the Sierra Butte mine. Rich ore is being taken out, but developments have not progressed sufficiently to determine the extent of the discovery.——At the Sovereign eight men are employed and an adit is being driven 1600 ft. to tap the shoot of ore opened in the Discovery shaft.——The Young America quartz mine, near Sierra City, is being examined for San Francisco interests.——Operations will be resumed at the Phoenix next week. It is planned to install an electric power-plant.—— The Gunn Mining Co. is completing a boarding house and bunk houses, and plans to erect a small mill. T. Elgie is superintendent.——Operations on the Colombo mine will be shortly resumed.

Alleghany, June 13.

A rich shoot has been cut by the drift at the Rose Quartz mine near Sierra City and a 500-lb. lot has been shipped to test the value.——A new mine-car has been packed from Downieville to the Sierra-Poorman mine.——F. H. Davis has secured a bond on the Oxford ground north of Downieville on the east side of the serpentine belt. Some excellent ore has been taken from the vein on the group and crushed in the mill that was destroyed by fire some time ago.——A. C. Wilkinson and S. P. Fellman have secured a bond on the Amethyst claim on Oregon creek near Forest.

SISKIYOU COUNTY

The Scott River Dredger Co., which has a bond on about four miles of Scott river, at Callahan, has stopped operations and will not continue the work of exploring the ground this year. The action of the company throws about 25 men out of work.

TRINITY COUNTY

B. E. Stevenson and J. A. Manaudas have taken a bond on the holdings of D. B. Fields, on Indian creek, for a company of French capitalists. The properties include both placer and quartz claims and cover 1552 acres of mineral land. There are several water rights that are included in the bond which carry over 500 inches of water the driest seasons of the year. The placer claims have been equipped with 4000 ft. of pipe to carry the water for washing the gravel, which has averaged between 11 and 14c. per cubic yard.——In the Yellow Jacket district William McLaren is taking a good grade of tellurium ore from his claims.—— J. L. Johnston is opening a 5-ft. vein in the Bonanza.—— The Trinity River Dredger Co.'s pony dredge was started at Poker Bar, two miles below Lewiston, on the Trinity river last week. The dredge will handle about 1000 cu. yd. per 10 hours, but the company will have another machine completed this fall that will have nearly double this capacity.

TUOLUMNE COUNTY

(Special Correspondence).—A small crew of men has been put to work at the Longfellow mine, preparatory to the resumption of mining operations. Fred Meyer is in charge.

——Bernard Brothers have let a contract for sinking the shaft at the Karnac an additional 50 ft.——According to a report the shaft at the App mine, now 1300 ft. deep, is to be sunk an additional 300 ft.——Work is soon to be commenced at what are known as the Oneto and Rosasco gravel mines, situated near Phoenix lake, by the Tuolumne Consolidated of California, recently organized. S. A. Knapp will be superintendent.——A company has been formed to drive an adit under the limestone belt at Columbia, in search of gold-bearing gravel in paying quantity. It is said that the preliminary work will be commenced within a few weeks.

Tuolumne, June 13.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—Development is in progress at the Standard property on Fall river and reserves of ore are now being blocked preparatory to the starting of the 50-ton mill. W. T. Chapple is manager.——A body of ore two feet wide has been cut in the west drift on the Magnolia vein run from the Rockford adit. Tests show values of 3.8 oz. gold and 2.6 oz. silver per ton.——The German mine in Virginia canyon, has been entered among the list of shippers. During the last week a test run on three tons brought a settlement of $190 per ton in gold and silver.——From 4 to 6 carloads of ore per week are being shipped from the Santiago mine in East Argentine. The product is brought to the independent sampler in Georgetown over the Argentine Central railroad. William Rogers is manager.——A heavy tonnage of ore is being marketed by the Waldorf Consolidated Mining Co. The 250-ton mill is running steadily and a fine quality of concentrate is resulting. It is estimated that there is ready for delivery over 2000 tons of smelting ore that will average $50 per ton.

Idaho Springs, June 11.

GILPIN COUNTY

(Special Correspondence).—The Brooklyn mine, in Lake gulch, has been taken under bond and lease by E. O. Fairchild and O. Q. Beckwith, of Denver. The machinery is being overhauled and placed in condition. The shaft is down 500 ft., and work of retimbering is now in order.——Shipments are in order from the Chicago-Carr mine, in Gregory district. All work is being carried forward under the leasing system.——The Ashtabula mine, in Perigo district, is to be equipped with a boiler, while the other machinery is being placed in condition. T. W. Wells is manager.——The old Pewabic dump has been leased by Charles Niccum, of Black Hawk. From four to five carloads per week will be shipped to the Hidden Treasure mill.

Central City, June 10.

GUNNISON COUNTY

Work at Gothic has been considerably retarded by the late snows this season and operations have only been started a short time in the Mountain King property which is being developed by the Elk Mountain Mining Co. Drifts have been started from the face of the cross-cut which opened the vein last year, and it is expected that one of the shoots will be found within the next 75 ft. The company is to install a water wheel and compressor in the canyon below the mine to furnish power for the drills. J. T. Bennett is superintendent.——Operations for the season have been started on the property of the Maroon Mountain Mining Co.——A force of men is at work grading for the foundation of the new 10-stamp mill which C. M. Carter is erecting at his claims on Ohio creek. A new bunk house for the accommodation of 30 men has been finished.

LAKE COUNTY

There has been considerable high-grade ore taken from the third level of the St. Louis property at Leadville. A 34-lb. brick was shipped to the Denver mint a few days ago that was made by melting picked specimens. The same streak has been found on the fifth level and an effort is now being made to catch it on the fourth.——Work has been started in the unwatering of the Helena shaft in Iowa gulch, and the ground will be ready to open in a few weeks.——A 500-ft. shaft is to be sunk on the Little Mary claim in Big Evans gulch and the ore which is supposed to be the extension of the Famous opened. The Yak tunnel passes a short distance from the proposed shaft and no trouble with water is anticipated as it is thought the tunnel will carry off any seepage.——Brown Brothers, who are operating the Ibex claim under a lease, recently shipped 18 sacks of ore to the smelter that was reported to assay several thousand dollers per ton.——The Colonel Sellers is to commence sinking in a short time.

OURAY COUNTY

The mill at the Thistledown mine near Ouray has been running steadily the past week effecting a saving of 72% of the lead in the ore.——The Camp Bird management is planning extensive development for this season and has increased the force at the mine. The production is keeping up to that of last year which averaged $225,000 per month.——F. M. Jackson, who has been operating the Wedge property for some time, has given a bond on it to a company with which John B. Farish is prominently identified.——The mill at the Revenue has been started and the company will put on an additional 100 men in the course of the next few weeks.——The development which has been carried forward for the past six months at the Atlas has reached a stage where enough ore can be mined to supply the mill continuously. The mill is making a good grade of concentrate and will soon be handling 100 tons of ore per day.——The San Pedro Mining & Milling Co. has let a contract to drive the main development adit 800 ft. from its present face which will complete the work. Eight veins have been cut during the progress and it is expected to open at least three more.——The old Poughkeepsie mine, in the Poughkeepsie district, has been taken over by an Ohio company which is to erect a mill and do considerable development work the coming season.——The development adit, nearly 1400 ft. long, at the Calliope, has been completed and the old workings are being re-opened.

SAN JUAN COUNTY

George Fisher has begun work for the season on his Big Ten group on Greene mountain, five miles southeast of Howardsville. A drift has been run on the Golden Egg claim of this group for over 600 ft. opening ore that assayed about $75 per ton with some that ran as high as $500 per ton. On the main group about 1000 ft. of development work has been done opening a large body of ore ready for stoping.——Work is soon to be started on the Russell group at Animas Forks in the face of the cross-cut that opened a 26-in. vein of ore last season.——The plant has been put in order at the Kankanee and a train of burros is packing in supplies. Some very high-grade ore has been opened in the underground work and the property should make a good showing this year.

TELLER COUNTY

High assays continue as development progresses on the orebody cut on the 1300-ft. level in the Vindicator property on Bull hill, and the vein is showing up strong as followed from this depth. The shoot is opened to the entire width of the drift, and as it contains small seams of high-grade, will average over three ounces gold per ton all the way across. The vein in the 1300-ft. level was cut at a point 400 ft. north of the shaft and lies 1200 ft. from the find made in the same mine two weeks ago. The No. 3 south vein, cut recently at a depth of 1400 ft. in the Vindicator, is appearing stronger than ever before and now measures over 15 ft. from wall to wall. Some of the ore exposed in this shoot assays several thousand dollars per ton, while the entire vein will at this time average more than $110 gold per ton. Samples taken from the new vein recently cut in the Jerry Johnson property on Ironclad hill returned assays as high as $1700 gold per ton. This vein is under development at a depth of 450 ft.——June 10 was pay day in the Cripple Creek district and over $315,000 was distributed for May wages.——The find made several days ago by Fred Johnson, lessee operating on the Pride of Cripple Creek, on Ironclad hill, is said to be improving as development work is carried on and the orebody opened now measures four feet from wall to wall. This vein lies at a depth of 630 ft. and assay returns show from 1 to 5 oz. gold per ton.——A number of leases have been granted on the Blue Bird mine, on Bull hill, and the mine will shortly be back on the ship-

ping list.——The Gold Dollar property on Beacon hill, operated by the Union Leasing Co., is making a fairly good production, the output averaging over 25 cars per month. Development work upon a large scale is being done on this ground and it is believed that before the closing of the present month the mine will be in shape to double the tonnage going out at this time. Two ore-shoots are opened and operations are conducted through the Mabel M. and Husted shafts. The ore shipped from the property is averaging $25 per ton.

IDAHO

IDAHO COUNTY

Joe Sugars, of Orogrande, and M. L. Derrigg, of Grangeville, have bought the 2-stamp mill on the Gold Dove claims and will move it to their Iola group near Orogrande. A cross-cut adit on the claims opened an 8-ft. vein at a depth of 60 ft. from which assays have been obtained as high as $125 per ton.——The adit at the Buckhorn claims on Four Mile creek is reported to have opened a shoot of high-grade ore, cutting the vein at a depth of 140 ft. The property is owned by C. E. Sample, J. H. Kingsley, and J. D. Wooden, of Spokane.——J. Asher Cowan, who recently secured a bond on the Center Star mine, north of Elk City, has commenced work. The adit will be driven ahead on the vein and a shaft sunk, while later construction on a road to bring in machinery will be started if the present development warrents it.——The re-adjustment of the American

Bunker Hill & Sullivan New Mill.

Eagle mill, on Seigle creek, was completed a few days ago and the 10 stamps are now dropping on ore. It is estimated that there are 500 tons of ore ready for the mill that will average $54 per ton.——Work has been started at the Jumbo mine in the Buffalo Hump district. The mill and machinery will be repaired and the mine thoroughly tested. ——There are 11 men working in the Lone Pine claim which is under bond to F. W. Bradley, and it is reported that the entire face of the drift is in high-grade ore.

SHOSHONE COUNTY

The directors of the Federal Mining & Smelting Co. have declared a dividend of $210,000, at the rate of $1.75 per share on preferred stock, payable on June 15 to stockholders on record May 27. This is the second dividend paid this year and brings the total to $420,000 for the year. With the payment of this dividend the Federal Mining & Smelting Co. will have disbursed $8,090,000 since its organization a few years ago. Of this total $5,381,250 has been paid on the preferred and $2,708,750 on common stock. The company has 60,000 shares of common stock issued and 120,000 shares of preferred, the par value of each being $100. ——The Caledonia Mining Co., owning the newest of the bonanzas in the Coeur d'Alene district, has increased its shipments to 40 tons per day. Some of the latest assays show 1200 oz. silver, and as high as 38% copper per ton. The ore is among the richest ever uncovered in the Coeur d'Alene. Seventy-five men are employed in the development of the property. The company has paid two dividends, amounting to $39,000 in two months and the third of $13,000 at the rate of 1c. per share is due.——The Gold Hunter Mining Co. is planning to drive an adit of two miles on its property near Mullan, making it the longest in the Coeur d'Alene. The adit will be driven from the Bell Mining company's old adit at Gem, and run through the Bell, Flynn, Wonder, and Star claims before tapping the Gold Hunter. The property is one of the largest shippers in the Mullan district.

MONTANA

BROADWATER COUNTY

B. Binnard, the president, and officers of the Radersburg Consolidated Mining Co., controlling the Ohio-Keating mine and the Manhattan-California mine, have left on a tour of inspection of its properties. The electric power-line has been completed to Radersburg and active operations are about to be resumed. It is the intention of the company to commence active development on the Manhattan-California property and it is expected that the equipment will be placed during the fall.

NEVADA

ESMERALDA COUNTY

The Goldfield Consolidated Mines Co. had another big month in May, according to the official figures just given out by J. R. Finlay. The figures for the month fall but a trifle short of those for April. The gross production for the month was $1,021,656, and the net profit $723,396. Mr. Finlay's report follows:

TONNAGE PRODUCED.

	Dry tons.	Assay oz.
Combination	4,656	1.18
Mohawk	6,549	1.32
Red Top	4,409	1.31
Clermont	4,204	2.63
Shipping ore from Clermont	691	25.88
Total	20,509	2.41

The gross value to be credited to the various mines are as follows:

Combination	$ 114,742
Mohawk	180,472
Red Top	121,136
Clermont	605,306
Total	$1,021,656

The performance of the mill was as follows:

Dry tons milled	19,818
Average value per ton	$ 32.89
Total value	$651,868
Loss in tailing	$ 31,260
Value realized	$620,628
Percentage extracted	95.20

EXPENSES.

General—	Amount.	Av. Per Ton.
Bullion tax and marketing bullion	$ 22,000	
Administration, etc.	21,000	
	43,000	$2.10
Mining	81,000	3.95
Transportation	3,000	0.15
Milling—		
Milling and cyaniding $51,000		
Marketing concentrate residues 16,000		
	67,000	3.27
Construction	40,000	1.95
Cost of marketing high-grade ore	33,000	1.61
Net cost	267,000	13.03
Loss in tailing	31,260	1.52
Total costs and losses	$298,260	$14.55
Profit per ton	$35.26	
Total value of ore	$49.81	
Total profit for month	$723,396.00	
Percentage of profit	70.81	

The Codd lease on St. Ives is to resume operations and will sink to a depth of 1500 ft.——The Combination Fraction has a force of men at work in the mill of the Nevada-Goldfield Reduction Co., and will commence milling as soon as the machinery is in good running order.

HUMBOLDT COUNTY

(Special Correspondence).—E. A. Montgomery and associates have decided to hurry the work on their property, adjoining the National mines.——W. L. O'Connell and associates are conducting developments on the Radiator and Auto Hill claims.——The Stahl lease on the National is extracting the richest ore in the district. A recent shipment of 1000 lb. netted $35,000, while a previous shipment of 800 lb. brought $25,000.——At Seven Troughs activities are pronounced and several leases are opening excellent ore.—— The Seven Troughs Co. is operating the Kindergarten, Therien, and other properties. On the 400-ft. level oreshoots have been developed for 600 ft. These, save for a barren zone of about 50 ft., are continuous and range in width from three or four inches to three feet. The ore assays well with an average about $30 per ton. On the 500-ft. level, which is being opened, the shoot has been driven on for a short distance.. The Kindergarten shaft, sunk to a vertical depth of 300 ft., is the main working avenue. The mill is running with one shift, but as soon as the new pump has been installed two shifts will be employed. L. A. Friedman is manager.——The company has a force of 85 men on its payroll.——The Engineers', Merger, and other leases are developing blocks of ground with satisfactory results. On the Merger lease ore assaying $50 to $100 per ton has been intersected.——The Chicago lease has secured a block of ground on the west ore-zone and will commence activities within a few weeks.——It is reported that negotiations are pending for the consolidation of the Seven Troughs Co. and the Florence Leasing Company.

Winnemucca, June 11.

LINCOLN COUNTY

Orders have been received at Pioche to start work on the Consolidated Pioche and the mine has been gotten in shape for extensive work.——After a brief shut-down the Gold Chief, in the Chief district, has resumed operations. A supply of distillate has been obtained at Caliente and work can be carried on without stopping till the railroad is repaired. The Gold Chief shaft is now down 400 ft. in ore that assays from $6 to $17 per ton.

NYE COUNTY

(Special Correspondence).—A movement is under way to organize a new company, known as the Dexter-Jumping Jack Consolidated Mines Co. to take over the Union No. 9 claim of Dexter and the Jumping Jack claim of this company, in order to avoid further apex litigation. The new corporation will have 1,250,000 shares, and will be controlled by the two parent companies.——The Rescue-Eola Co. has filed articles of incorporation with the county clerk. The company, composed of San Francisco capitalists, plans to assume the debts of the Rescue Consolidated Mining Co., and resume operations on the property.——The Flemming lease on National Bank is driving the east cross-cut at a depth of 300 ft. A gasoline hoist has been installed and the compressor moved to the lease from the main workings.

Tonopah, June 10.

OREGON

BAKER COUNTY

The White Points Gold Mining Co. is opening a group of five claims east of Sumpter with good results. A 400-ft. adit has been driven that tapped the vein at a depth of 300 ft., and drifts are now being run on the ore.——Mikle & Gleason have been prospecting the Mero group, near Bourne, this season with good results. The vein has been opened in several places, the assays from which averaged about $10 per ton.——Work has been resumed on the Mammoth property near Sumpter which has been operated by A. Bodleson for several years. The property is equipped with a mill and it is understood that work will be continued on a larger scale than before.

GRANT COUNTY

The Virginia mine on the head of Olive creek in the Greenhorn district is being unwatered and will be thoroughly sampled. Several portions of the mine have been very rich, one pocket having been opened that produced $50,000 worth of ore.——At the Ophir mine, in the Susanville district, the operators are stoping on a 5-ft. vein at a depth of 300 ft., on which level drifts have opened the shoot a distance of 75 ft. The 10-stamp mill is kept running night and day showing a good value on the plates and shipping concentrate to the Sumpter smelter that assays well.

UTAH

JUAB COUNTY

Some of the best ore that has ever been shipped from the Iron Blossom property is now being mined on the 500-ft. level of the No. 1 workings, the average being about $65 per ton though portions are much higher. Twenty tons per day of this grade of ore is being shipped. The board of directors has declared a dividend of 6c. per share, payable June 25.——The work of developing the Governor property through the Star Consolidated shaft has been started. The Star is now part of the Black Jack group and it is

Eastern Nevada and Western Utah.

through the 300-ft. level that the Governor ground will be reached.——Operations are to be resumed at the Crown Point.——The Lehi-Tintic Mining Co. has let a contract for 300 ft. of cross-cutting on its ground in the North Tintic district.——At the meeting of the directors held in Provo recently the Colorado Mining Co. declared a dividend of 8c. per share to be paid June 20.——Sinking is to be resumed at the Sioux Consolidated in the 450-ft. shaft. The drift, which is being driven toward the old workings is now out over 1100 ft., and is expected to open the ore any time.

PHILIPPINE ISLANDS

The Bua mine, in the Benguet district, recently shipped a $5000 bar of gold, the result of the mill-run during April. There are nearly 100,000 tons of ore blocked out in the mine which assays from $5 to $10 per ton. The company is to move the present plant to a more favorable site some time soon, and add another battery to the mill.——The dredge of the Philippine Gold Dredging Co. is to be started on a strip of ground on the Malaguit river, the owners of the dredge to receive 40% of the net profit.——The Syndicate Mining Co., operating in the Masbate district, is to issue ₱25,000 of its treasury stock to continue development. Some fair ore has been opened and the company will erect a mill if the results of the planned work are as satisfactory as the ground now opened.——The Colorado Mining Co., of Masbate, has completed the grading for the foundation of a 20-stamp mill and will have the plant completed late this fall. There are several veins on the property one of which is 16 ft. wide, the ore assaying about $10 per ton.——The Mayot Mining Co. is developing a group of claims on Gold creek in the Benguet district. Over 3600 ft. of work has been done on the property opening ore that averages $8 per ton.——The Headquarters Mining Co. is preparing to install its new mill which was ordered a short time ago. The company has purchased a cyanide plant from the Atlantic Gulf & Pacific Co. which will be erected with the mill.

BUTTE MINE PRODUCTION

Production, cost, and earnings of the Butte companies for the year ended June 1, 1910, are given below.

ANACONDA

Tons of ore mines		1,372,402
Gross value of ore		$11,158,517.73
Cost of mining	$5,558,527.64	
Freight on ore	165,973.20	
Cost of production	2,845,861.77	
Marketing charges	1,273,294.94	
		9,843,657.45
Net proceeds		$1,314,860.28

BOSTON & MONTANA

Tons of ore mined		1,291,343
Gross value of ore		$13,125,554.43
Cost of mining	$4,763,583.86	
Freight on ore	813,639.47	
Cost of reduction	3,579,893.35	
Marketing charges	1,011,644.87	
		10,168,761.58
Net proceeds		$2,956,792.93

BUTTE & BOSTON

Tons of ore mined		377,106
Gross value of ore		$3,707,264.79
Cost of mining	$1,265,916.24	
Freight on ore	72,669.96	
Cost of reduction	918,921.63	
Marketing charges	380,453.62	
		2,667,994.13
Net proceeds		$1,039,270.34

WASHOE

Tons of ore mined		203,508
Gross value of ore		$1,549,640.58
Cost of mining	$785,728.29	
Freight on ore	24,516.00	
Cost of reduction	416,290.97	
Marketing charges	151,000.05	
		1,377,535.31
Net proceeds		$172,105.27

TRENTON

Tons of ore mined		150,867
Gross value of ore		$1,334,224.71
Cost of mining	$649,896.89	
Freight on ore	18,328.03	
Cost of reduction	301,692.01	
Marketing charges	129,214.91	
		1,099,132.34
Net proceeds		$236,092.37

PARROT

Tons of ore mined		88,416
Gross value of ore		$652,093.36
Cost of mining	$532,962.16	
Freight on ore	12,164.25	
Cost of reduction	180,505.25	
Marketing charges	74,958.24	
		800,589.90
Net proceeds		$148,496.54

NORTH BUTTE

Tons of ore mined		430,124
Gross value of ore		$4,217,604.82
Cost of mining	$1,612,921.73	
Freight on ore	51,614.30	
Cost of reduction	1,798,407.12	
		3,462,913.15
Net proceeds		$754,661.67

RED METAL

Tons of ore mined		547,463.43
Gross value of ore		$1,839,126.31
Cost of mining	$2,007,771.81	
Freight on ore	101,355.34	
Cost of reduction	2,031,616.25	
		4,143,743.47
Net proceeds		$695,382.87

ALICE GOLD & SILVER

Tons of ore mined		1,415
Gross value of ore		$17,319.60
Total cost of production		20,701.45
Net loss		$3,381.85

The net earnings of the same companies for 1909 were: Anaconda, $2,079,891.28; Boston & Montana, $1,404,783.09; Butte & Boston, $646,198.24; Trenton, $136,898.40; Parrot (loss), $12,220.83; Washoe, $153,414.48; North Butte, $1,839,442.78; Butte Coalition, $159,160.86; Alice, $3,810.01. The total increase for the year was $316,090.91.

COPPER PRODUCERS' ASSOCIATION figures made public June 8, show an increase of stocks on hand June 1 of 18,441,814 lb. over May 1. Stock on hand June 1 was 160,425,973 lb., an increase of 18,441,814 lb. over May 1; May production, 123,242,476 lb., an increase of 5,764,837 lb. over April. Total deliveries during May, 104,800,662 lb., an increase of 5,482,308 lb. over April. Of the deliveries 45,495,440 lb. were for export, an increase over April of 14,167,037 lb., while 59,305,222 were delivered to domestic consumption, a decrease from April of 8,680,729 pounds.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

EDGAR COLLINS is in San Francisco.

FRANK M. WATTS is now at Los Angeles.

E. A. SPERRY has returned to Sacramento.

COURTENAY DE KALB has gone to New York.

J. W. D. MOODIE has returned to Los Angeles.

L. A. GREENE has returned from Los Angeles.

E. B. KIRBY was in San Francisco Wednesday.

J. MORGAN CLEMENTS was at Los Angeles recently.

MARK B. KEAR has gone to Trinity county, California.

GELASIO CAETANI and LIONEL LINDSAY are at Austin, Nevada.

E. H. MESSITER has removed his office to 25 Broadway, New York.

S. H. WIMBERLEY is with the Homestake company at Lead, South Dakota.

G. LAVAGNINO, of Pasadena, California, is spending some time at Salt Lake.

CHARLES KIRCHHOFF is attending the International Congress at Düsseldorf.

FRANK W. ROYER was in San Francisco last week on his way to Mexico City.

JOHN A. ROOK is mining engineer for the Atlas Mining Co., at Whitehorse, Yukon Territory.

O. H. PACKER has returned from examining and locating placer ground on Middle Fork of Feather river.

CHARLES M. MULLEN, now of Portland, Oregon, but long connected with mining in Colorado, is visiting San Francisco.

J. B. TYRRELL has been elected a Fellow of the Royal Society of Canada.

H. F. LEFEVRE has returned to New York after an absence of ten months spent in Guatamala, Salvador, Nicaragua, and Costa Rica.

PHILIP WISEMAN has left Los Angeles for New York by way of Portland and Butte. He will sail for Europe on the *Lusitania* June 29.

HOWLAND BANCROFT, of the United States Geological Survey, has resumed field work on the ore deposits of northeastern Washington.

LAWRENCE ADAMS, late vice-president and general manager for the Guanajuato Amalgamated, is leaving New York for Montana and California.

CARL F. DIETZ and DYKE V. KEEDY, of the firm of DIETZ & KEEDY, metallurgical engineers, of Boston, have gone to Nova Scotia for Boston clients.

S. F. SHAW, general manager and consulting engineer for the Montezuma Mines of Costa Rica, has gone to Montezuma, Costa Rica, where he will be engaged for several months.

W. MURDOCH WILEY and R. B. LAMB, of New York City, have left for Montana to examine the Ohio-Keating mine. They will also make mine investigations in Idaho and California.

R. L. BARTLETT, recent graduate of the course of mining geology of the Mass. Inst. Technology, has accepted a position with FREDERICK G. CLAPP, geological engineer, Pittsburg, Pennsylvania.

L. Vogelstein & Co. give the following figures of German consumption of foreign copper for the months January to April, 1910:

Imports of copper	57,322 tons
Exports of copper	2,658 tons
Consumption of copper	54,664 tons

as compared with consumption during the same period in 1909 of 46,619 tons. Of the above quantity 50,784 tons were imported from the United States.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

LOCATION OF CLAIM—ASSESSMENT WORK

Where a junior locator contended that annual assessment work was insufficient because the work was done for the purpose of representing several claims, a court, in determining the sufficiency of the work, will apply the labor shown to have been done to the particular claims upon which the work was in fact done.

Swanson *v.* Kettler, (Idaho) 105 Pac., 1059, Jan. '10.

LOCATION OF CLAIM—ABANDONMENT

A senior locator, possessed of a paramount right in mineral lands for which a patent is sought, may abandon such right and thereby render the ground covered by such location subject to re-location before the expiration of the statute of limitations within which the annual labor must be performed. And upon application for a patent a junior locator may show, as against the senior location, that the ground covered by such senior location had become a part of the public domain so as to be subject to re-location even before the expiration of the statutory period for performing the annual labor, by showing that there had been an actual abandonment of the claim by the first locator.

Swanson *v.* Kettler, (Idaho) 105 Pac. 1059. Jan. '10.

LOCATION OF MINING CLAIM—RIGHT TO PATENT

A person who has initiated a right to a mining claim, recording his location notice, and performed the other acts made necessary by law, will be entitled to a patent on application, unless adverse rights are set up in the mode provided by the statute. And in an application for a patent by a junior locator, upon the failure of the senior locator to adverse, it will be presumed that there was no senior location, and that at the time the junior location was made the ground was open to entry under the mineral laws of the United States, but where it is made to appear that there is a third location made subsequent to such junior location, such third or subsequent locator may adverse the application for patent by the junior locator, and show that the junior location was void, because when made the ground was not open to location under the mineral laws.

Swanson *v.* Kettler, (Idaho) 105 Pac. 1059. Jan. '10.

LOCATION OF CLAIM—AMENDMENT OF CERTIFICATE

If the certificate of the original location of a mining claim was insufficient because so defective as to prevent identification or designation of the claim on the ground, an amended certificate cannot be filed curing the defect where it includes other or different territory so as to injure intervening rights.

Washington Gold M. & M. Co. *v.* Olaughlin, (Colo.) 105 Pac. 1092, Dec. '09.

PRIORITY OF LOCATION—FRACTIONS OF A DAY

Where the relative priority of conflicting mining locations depends on the exact hour of the day of the filing of a location certificate, fractions of a day must be taken into account; and where a location certificate, not filed within the statutory time was filed in advance of the filing, on the same day, of a junior location certificate, in a controversy as to the pirority, the former was held to be prior in time.

Washington Gold M. & M. Co. *v.* Olaughlin, (Colo.) 105 Pac. 1092, Dec. '09.

CONVEYANCE OF COAL LANDS—RELEASE OF DAMAGE FROM WORK

Where the grantors of coal under land released all claims for damages by the working of the mines in a proper manner, the removal of all the coal was not an improper working; and where a subsidence of the surface was caused thereby, the owner of the surface under such release had no right of action for damages.

Kellert *v.* Rochester & Pittsburg Coal & Iron Co., (Pa.) 74 Atlant. 789, Oct. '09.

Publications Received

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

SURFACE WATER SUPPLY OF THE UNITED STATES, 1907-8. PART V. UPPER MISSISSIPPI RIVER AND HUDSON BAY BASINS. By A. H. Horton, E. F. Chandler, and R. H. Bolster. U. S. Geol. Surv., Water-Supply Paper 245. Pp. 133, ill., index. Washington, 1910.

MODERN ASSAYING. By J. Reginald Smith. Pp. 145. Ill. J. B. Lippincott & Co., Philadelphia and London. Price $1.50.

This little book is the latest on the assaying of ores, and is direct, comprehensive, and plain, a book that is both technical and practical. It is profusely illustrated and likely to become popular with those who wish a knowledge of assaying without the expense and time of a special course in a technical school. Considerable space is devoted to the assaying of ores by wet, as well as fire methods.

A HISTORY OF THE LOGARITHMIC SLIDE RULE AND ALLIED INSTRUMENTS. By Florian Cajori. Pp. 125. The Engineering News Pub. Co., New York. Price $1.

This volume is one of the most complete treatises of the many thus far published on the subject of the slide rule and its uses. In these days, when 'time is money', the engineer employes the slide rule to reduce the mental labor of mathematical computation, and this book gives a history of this valuable type of instrument, and explains its varied uses, so that anyone may employ it to advantage.

THE CORROSION AND PRESERVATION OF IRON AND STEEL. By Allerton S. Cushman and Henry A. Gardner. Pp. 373, ill. McGraw-Hill Book Co., New York. Price $4.

This is a treatise on a subject which cannot fail to be of interest and value to all who are using iron and steel for structural purposes. It goes thoroughly into the problem, and various expedients are suggested to prevent, or lessen, the destruction of iron and steel by corrosion due to electric currents or to other causes. The book will be of particular usefulness and value to architects and engineers whose work deals largely with structural steel.

THE CYANIDE HANDBOOK. By J. E. Clenneli. Pp. 520, ill. McGraw-Hill Book Co., New York. Price $5.

This is the latest addition to the extensive literature descriptive of the cyanide process, and one of the best. The history of the process and its chemistry, is reviewed at length. The chapter devoted to the preparatory treatment of ore for cyaniding, is of peculiar value, as it describes in detail the various types of machinery employed in crushing and grinding the ore; the mechanical contrivances for handling the material, both direct and old accumulations of tailing. Hydraulic classification, and the various metallurgical processes which commonly precede cyanidation are treated at length and considerable space is devoted to special modifications of the cyanide process; to testing as to adaptability and other essential features of the treatment of ores by the process.

New Oilfields Map

William Forstner is preparing a map covering the oilfields of the west side of the San Joaquin valley from Coalinga to Sunset, including the Carizo valley in the eastern part of San Luis Obispo county. This map will give the names of owners and claimants to the parcels of land, with the character of the ownership or claim; whether agricultural patents and mineral entry, pending homestead entry, lieu selection, desert-land entry, State selection, mineral application, or mineral location; giving the exact status of all ownership and claimants, as gathered from the public records. The map will be on the scale of one inch to the mile, and about 10 ft. long by 3½ wide. As only a restricted number will be published, orders should be sent to Mr. Forstner in advance.

Drilling 'Man-Size' Holes

Work recently performed by the War Department through the corps of engineers with a Terry core-drill has established beyond doubt the practicability of drilling bore-holes 30 or 40 in. diam., vertically or at an angle, and to any reasonable depth. The drill used was of the class D type and equipped with tools for boring a 29-in. hole. The work was in New York, and the material bored through was a trap concrete embankment. Some of the drilling was done in places where the bore-holes penetrated cement reinforced by steel beams, and elsewhere iron drain pipes and the like intersected the line of the bore-hole. All of the holes drilled were at an angle, and the average cutting rate was 2 ft. per hour. In the illustration below are shown parts

Drill Cores Made With Terry Drill.

of some of the core removed from a hole drilled at an angle of 55° from the vertical. In one of these cores there is embedded a section of an 8-in. eye-beam, and in another an iron pipe 2 in. diam. Both the steel beam and iron pipe were severed without any appreciable reduction in the speed of cutting. The wear on the bit was one-quarter of an inch per foot cut and ten pounds of shot was used in drilling the same distance. Numerous seams and openings caused by imperfect setting of the cement, as well as severed pipes large enough to drain in a few minutes the water from an ordinary bore-hole, offered not the slightest hindrance to the work. Irregular and broken formations are of no consequence in drilling large holes, as has been demonstrated in similar operations. The detritus or sludge from the kerf is sufficient to close all save large seams or crevices and through them the heavy tools under a high momentum advance with remarkable rapidity.

Details regarding the work are given by Captain H. L. Wigmore, as follows:

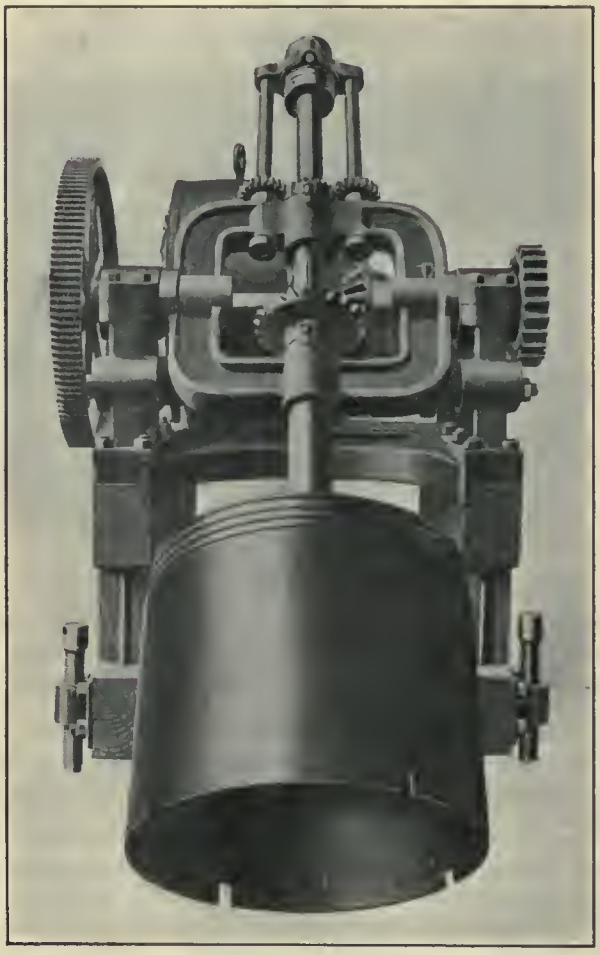
(1) April 18: a 28-in. diam. bit, inclination of shaft 54° 22' with the vertical, cut 37 in. through concrete in 2 hours and 40 minutes, actual running time. (2) April 19: 36 in. cut through the same class of material in one hour, actual running time. (3) April 20: 31 in. cut through concrete and 8-in. steel beam in 2 hours, actual running time. (4) April 22: 33½ in. cut through concrete and 2 in. wrought-iron pipe in 1 hour and 15 minutes, actual running time.

In making the above statement it is understood that the total time consumed in drilling the lengths stated was considerable more than the time given, as many delays for different reasons are continually occurring in work of this nature. The space available where this drill was used was exceedingly limited and the work was much slower than would have been possible with longer runs. In three days, April 18, 19, and 20, counting all delays, a total progress was made of 104 in. In cutting a total of 14 ft. of hole a wear on the bit valued at $5.25 was reported. Consumption of oil, waste, grease, and shot for drilling the above 14 ft. is reported at $2. In a similar hole of only 6 ft. in length, a wear on the bit valued at $6 was reported, and consumption of shot, oil, waste, etc., valued at $1.

This statement shows that in drilling 29-in. holes through

trap concrete, steel beams, and iron pipes, 138 in. was cut in 414 minutes, or 1 in. every 3 minutes; this is equivalent to 20 in. drilled per hour. In drilling 20 ft. through the same material the cost of wear on the shot-bit was 56c. for each foot drilled.

In mining operations, where the head room will permit, these drills can be profitably employed for sinking winzes or boring holes for use as ore-chutes. Such operations are now being conducted with a Terry drill in a large mine in northern New York. It is, however, to those concerned in the ventilating of mines, and of coal mines in particular, that this subject should be of the greatest interest, both



Terry Core Drill.

from an economic and humanitarian point of view. Several holes 30 in. or more in diameter can be drilled for the cost of sinking a single shaft, and if properly placed they would supply a circulation of air to the workings much better than that obtained through a single shaft. The size of these holes would be ample for the installation of permanent ladder, and they would serve as exits in case of accident, and as such they would be of the greatest assistance in rescue work. There would be much less difficulty in reaching and extinguishing mine fires, which under present conditions are oftentimes so situated as to be inaccessible, and therefore continue unmolested until checked at some place remote from their origin. To be able to reach a fire quickly, and while still in the incipient stage, would save enormous sums hitherto wasted for lack of a vantage point from which to begin the attack. Apart from providing a means of ingress and egress for miners, these large bore-holes would supply to the workers a wholesome atmosphere under more natural conditions than at present. At each opening could be installed an electrically driven fan which would force air into the workings or exhaust the air from the mine as needed. Ventilation is not the only purpose for which these bore-holes could be advantageously used, for they could serve as conductors for pipes and cables, and would in many cases shorten the distance to which such lines must be carried. To some these suggestions may seem impracticable, or the cost prohibitive. As a matter of fact such is not the case, but even if the actual cost were high, it would appear that any cost would be reasonable which would provide a method whereby life and property would be conserved. To the mine owner this method of ventilation offers the cheapest insurance he can procure, and the improved working conditions it would afford within the mine would stimulate those of a higher order of intelligence to seek therein employment where hitherto they would not venture.

CATALOGUES RECEIVED

THE DEISTER CONCENTRATOR CO., Fort Wayne, Indiana. 'Deister Ore Concentrator No. 2'. Illustrated. 12 pages. 5½ by 8½ inches. 'The Improved No. 3 Deister Slime Concentrator'. Illustrated. 16 pages. 9 by 6 inches.

GALIGHER MACHINERY CO., Salt Lake City, Utah. Catalogue B, showing complete line of mining machinery and supplies including everything from blasting fuse, hand-hammers, up to rock-drills, compressors, hoists, vanners, and the like. An unusually complete index adds materially to the usefulness of the volume. Fully illustrated. 520 pages. 5½ by 8½ inches.

COMMERCIAL PARAGRAPHS

The Chicago office of the POWER SPECIALTY CO. has been moved to the Peoples' Gas building. The business in that territory is in charge of R. B. Nutting.

The NATIONAL ORE CONCENTRATION CO., Chicago, has recently shipped an order of Woodbury jigs to the Braden Copper Co., of Valparaiso, Chile.

The HARBISON-WALKER REFRACTORIES CO., Pittsburg, advises that J. J. Brooks, Jr., its general sales manager, has recently been elected to the directorate of the company.

WARREN C. BOGUE has organized the BOGUE SUPPLY CO., and has established office and yards at Seventh West and Third South streets, Salt Lake City, to buy and sell mine and mill equipment.

THE DORR CYANIDE MACHINERY CO., Denver, Colorado, advises that among its recent orders is one for 10 Dorr classifiers and 8 large thickeners for the Santa Gertrúdis company, at Pachuca, Mexico.

EDWIN H. MESSITER has opened an office as a consulting engineer at 25 Broad street, New York City, and will make a specialty of problems connected with handling of materials in metallurgical plants.

The DODGE MFG. CO., Mishawaka, Indiana, is distributing a chart showing, by a four-color half-tone, the action of the Eureka water softener and purifier. As an example of the best in mechanical illustrations this chart is pre-eminent and deserves careful study of the process which it illustrates.

THE DENVER ROCK DRILL & MACHINERY CO., Denver, Colorado, is now associated with the International Steam Pump Co., of New York, and will handle all the business of the latter firm in the Denver, Salt Lake, and El Paso territories. A large stock of machinery will be carried at each of these three points.

The Cananea Consolidated Copper Co. is increasing its roasting plant and has placed an order with ALLIS-CHALMERS CO. for six McDougall furnaces. These are exactly like the four furnaces which they now have in service. The furnaces have an outside diameter of 18 ft. 6 in. and are 32 ft. high. They are the six-hearth type.

THE C. O. BARTLETT & SNOW CO., Cleveland, Ohio, reports the following recent sales: Grasselli Chemical Co., three sets of heavy crushing rolls, and elevating and conveying machinery; Jacobs Asbestos Mining Co., Thetford Mines, W. P. Q., Canada, one special Common Sense pan conveyor, 250 ft. centres; capacity 150 tons of asbestos rock per hour; National Carbon Co., Cleveland, Ohio, elevating and conveying machinery; Pennsylvania Salt Co., Philadelphia, Pa., elevating and conveying machinery; Diamond Rubber Co., Akron, Ohio, two drop forge chain conveyors for conveying tire core, 120 ft. centres.

EDITORIAL

THE Congress of Inventors set for June and to be held at Rochester, New York, has been postponed till October. It will be held then unless new cause for delay be invented.

GOLD from the spring clean-up at Fairbanks has begun to arrive at Seattle. A shipment of $305,000 was received June 18, and $1,000,000 in addition is known to be on the way.

ST. MICHAEL harbor is at last open, steamers having been able to land June 19. It is reported that ten ocean-going vessels and fifteen river steamers were waiting for the break-up of the ice.

STATEHOOD is at last to be the portion of Arizona and New Mexico, though under the act just signed we shall probably not be permitted immediately to extend the welcome mining men in particular have long had waiting. In the meantime, don't crowd, gentlemen. There can only be four Senators.

PUEBLO, Colorado, is making extensive preparations to entertain the National Irrigation Congress, September 26 to 30. Irrigation and mining, the peculiar interests of the Western States, have much in common, and it is significant of their close relations that the Irrigation Congress will assemble in the Mineral Palace.

SEISMOLOGICAL studies are not as yet to be taken up by the United States Government. Mr. Hale, the venerable senator from Maine, characterized the project as 'absurd and sentimental' and the appropriation was accordingly refused. The narrowly circumscribed outlook illustrated by the remark is perhaps one reason why Mr. Hale is serving his last term.

PROGRESS in ore treatment at Kalgoorlie has not been made except through expenditure of much good money and hard work, as is shown elsewhere in this issue by Mr. M. W. von Bernewitz, the accomplished metallurgist of the Associated Northern Blocks (W. A.), Ltd. The account is taken from an unusually good illustrated description of the gold mines of the State, edited by Mr. H. V. Courtayne of the *West Australian Mining, Building & Engineering Journal.*

THE SUMMER SCHOOL is a well recognized institution in America. The mining colleges have generally conducted their summer courses in the field. The Missouri School of Mines is, however, to try this year a summer course in assaying, metallurgy, and related subjects carried on in the labora-

tories at Rolla. It has often seemed to us that there was an especial field for summer courses devoted to coal mining since, in general, the coal mines are less active during that season and an opportunity would be afforded the more ambitious workmen to prepare themselves for advancement.

WET METHODS of assaying have never been successfully applied to gold ores. The portability of apparatus suitable for such a method has led to many attempts to develop one that would be reliable. In our issue of last week we publish a scheme recommended by Mr. Robert DeLuce, and this week we give the results of a series of careful tests of the method made by Mr. James W. Howson. Evidently, as Mr. Howson concludes, this particular method while imperfect warrants further investigation. We shall be glad to hear from others.

STEWART and the Portland Canal district of British Columbia have led to much speculation this year. There seems to be no doubt as to the presence of good veins and the probability of important production. All this may be conceded and yet a word of caution be in order. Shares in the three leading companies, the Red Cliff, Portland Canal, and Stewart, have reached prices indicating a popular estimate of the combined value of the properties amounting to over seven million dollars.

BOTH coal miners and coal operators in Illinois seem to have settled down for a long and bitter contest. A number of operators have broken away from the association and signed the new scale but on the whole these defections have been few; much fewer probably than were anticipated by both miners and operators. The United Mine Workers withdrew the pumpmen and emergency workers, and the operators retaliated by announcing that they would recognize a separate engineers' and pumpmens' union if formed, which was promptly undertaken. There has been little disturbance of the peace and, while feeling is bitter at many points, so far there has been no rioting. The men insist that the operators shall pay for the short-firers, which the companies maintain is impossible in view of the competition they must meet.

Inspection of Mines

Mine inspection and various other means of increasing safety in the mines are now, fortunately, attracting much attention. We are glad to note especially that the interest is not confined to the coal mines. The program of the Mine Inspectors Institute, which has been meeting at Chicago, included such subjects as 'Timbering in Metal Mines', discussed by Mr. F. Cushing Moore, State Mine Inspector of Idaho, and 'The Education of Mine Employees' by Mr. H. H. Stock, of the University of Illinois. The American Mining Congress has been attempting for some years to frame a model law which might be recommended to the various mining States. The committee having the matter in charge, consisting of W. R. Ingalls, J. Parke Channing, James Douglas, John Hays Hammond, and J. R. Finlay, have worked with unusual care and will probably be ready to report at Los Angeles this fall. The report is sure to be a notable one and ought to be productive of much good. In the meantime Mr. Finlay is showing what the companies themselves can do in advance of legislation. A department of inspection has been organized at the Goldfield Consolidated, with Mr. Heath Steele in charge. The men have been invited to make suggestions with regard to anything that may be done to make safer any machinery or equipment in any part of the property of the company. Many changes have been made already and more improvements in plant and methods are in view. Mr. Finlay feels that while the Goldfield mine is one in which work is less dangerous than usual rather than the reverse, that is no excuse against taking every reasonable precaution and the details given on another page indicate that the aim is at a practice as exceptional as is the production of the great mine that he manages.

Prospectors and Geologists

Idaho's senior Senator, Mr. W. D. Heyburn, is a forceful man with a cutting tongue. Under the rule of Senatorial courtesy, he makes, uncontradicted, a good many statements that in the expressive language of the mining camp are 'bunk'. In the course of a recent speech he said, for example, that "no geological expert ever discovered coal." This will be news to the officers of the Colorado Fuel & Iron Company, which for many years employed Mr. R. C. Hills as geologist for the express purpose of discovering coal, and which in some fashion as a result of his work found and acquired large tracts of ground containing a black material that burns and otherwise fulfills all the purposes of coal. Mr. Robert Forrester, who performed a similar service for the Utah Fuel Company, is proud of the title of geologist and is certainly expert. Mr. E. T. Dumble, so well known as State Geologist of Texas, did such excellent work for the Southern Pacific in the coalfields of Coahuila, that he and a whole corps of geologists are now employed by that corporation. It would probably be hard to convince Mr. Julius Kruttschnitt that Mr. Dumble never 'discovered' any coal.

It will not do to argue that these men and others of their like, merely examined and reported on discoveries already made by some 'poor prospector'. A case falling within the experience of Mr. Bailey Willis while employed by the Northern Pacific, more nearly illustrates the true relation. In the heavily timbered and drift-covered coalfields of Washington, outcrops of any sort are rare. Mr. Willis, finding coal on a certain Section 18 and determining from the dip of the rocks a synclinal structure should bring the same bed near the surface in Section 13, sent his foreman and drill crew to the centre of that section with instructions to drill. They found coal within a few feet and thereafter had a great respect for the knowledge of Mr. Willis since they knew he had never been on the land nor had probably any other white man. The prospector has much to his credit. His intelligence, optimism, and patience have worked wonders in the development of the West but in giving him full credit it is not necessary to deny alto-

gether the efficiency of other men's work. To do so argues the limitations of the speaker's mind or a deliberate desire to mislead by an appeal to the gallery.

Americans and Chinese Railways

Since the Brice syndicate died an unlamented death Chinese railways have not been favorably considered by American investors, and American participation in railway building has been even less favored by the Chinese. Our initial effort gave an unfortunate introduction. The Brice fiasco was the most ordinary of promotion enterprises. As little as possible was given and as much as might be was exacted, with a view to quick profits rather than sound railway building. Ultimately, it will be recalled, the Chinese bought back the concession for $6,750,000, borrowing the money from the British. The price covered 32 miles of road and 50 miles of earthwork, and $3,500,000 of the amount was figured as a compounding of future profits. The transaction was finally closed, to the great relief of all concerned, through the good offices of J. P. Morgan & Company. Since then Americans have been in disfavor at Pekin, so far as railway concessions were concerned, and, on this side, popular interest in Chinese railway building has languished. This condition is unfortunate, since in many ways American experience and practice in railway building is eminently suited to Chinese conditions. Much of the present unrest in China over foreign loans for railways has risen from the English and continental plan of making the initial outlay on the basis of a road to last all time and to be capable of handling at once all of its ultimate traffic. European engineers spend more than we do on permanent improvements and as a result start with a heavier initial capitalization. In America roads have been built on the basis of the least possible first expenditure and of making betterments from earnings. It was on this basis that the great system of American railways was built, and it is because of the flexibility of the plan that the system grew so rapidly. A not less important consequence is that the railways belong in the main to our own people. In a broad sense, despite being at the time a poor people, we paid for our roads as they were built.

The Chinese would do well to follow our example. So far as concerns capital available for railway building, they are, as we were, poor. They have greatly the advantage in that the potential earnings from their lines are larger and traffic will in most cases develop more quickly. Indeed, at many points it merely waits the coming of the rails. In the Pekin-Kalgan line they have shown their ability to build substantially at low cost, and in the Imperial Railways of North China, to operate with an unusually favorable ratio of net to gross earnings. They should not hesitate to borrow the amount necessary to build the needed lines, but they may well hold out for better terms than they have been generally granted, and particularly for full control over the property.

At present there are two lines under consideration, in which Americans are interested. The Hankow-Sze Chuan railway has been much discussed and it is again announced that negotiations for its building have been completed. English, German, French, and American bankers are to participate in a loan of $30,000,000 to finance it. The line is a most important one, extending from the great interior seaport of Hankow at the head of deep-water navigation, westward through a populous country and along a line where a rich trade already exists. Some of the construction work will be heavy owing to mountain grades. The second line, and in many particulars the more significant one, is that from Chinchow on the Imperial Railways of North China, to Aigun on the Amur river. The distance is about 750 miles and the situation corresponds roughly to a proposal to build from Chicago to Winnipeg, supposing no lines were in operation save the Northern Pacific from Duluth west through St. Paul, to which Tsitsihar, near which the new line will cross the Chinese Eastern, may be taken to correspond. The country is a broad valley or great open plain across which construction will be cheap and easy. It is only sparsely inhabited and constitutes, with Mongolia, the natural area into which the Chinese surplus population should flow. The soil is good and the climate favorable. Much of the territory is not greatly different from Iowa and southern Minnesota. It is corn land, and even as far north as the Amur river a deciduous palm is present. At Blagoveschenk, apposite Aigun, the summers are positively hot and the winters not colder than in the Mississippi Valley. It is China's most available unoccupied territory, and economic as well as strategic reasons demand that the road be built. American and British firms have undertaken to supply the capital, to the amount of $30,000,000, at a rate of 5 per cent interest, leaving full control of the line in Chinese hands. The requirement of foreign engineers and payment of commissions on purchases has been waived, and, in short, the terms are the most liberal that have been given to the Chinese. The proposal is backed by American banking firms abundantly able to carry the matter through without outside appeals, and is not therefore a promotion matter, but a sound business enterprise. Difficulties have been raised by both Russia and Japan, but essentially they rest on strategic grounds. In the long run economic conditions are bound to control, and the right of China to build roads where she pleases in her own territory can hardly be permanently contested. In the meantime the suggestion has been made that Japan and Russia join in the enterprise, and this is a sound suggestion, since everything which makes toward the neutralization of Chinese railways in their political aspects, makes toward peace. The more the Chinese can be led to develop their own resources, the less danger there is of conflict, and the further the world moves from the old 'spheres of influence' notion, the better. America has been the historic friend of China, and in the new phase of development of the ancient Empire America has everything to gain and nothing to lose by continuing that attitude. No special privileges are desired or desirable. From the Brice syndicate to the Chinchow-Aigun terms, marks progress in America as well as in China.

BY THE WAY

The relations between the work of the geologist and of the prospector have been discussed recently in a *Press Bulletin* circulated by the United States Geological Survey. From it the following is abstracted:

The question is often asked by those who have made only superficial observations of geological work on mineral or ore deposits: "Why does the prospector discover a greater number of valuable mineral deposits than the mining geologist?" The answer might be "Because there are more prospectors than geologists," but a better answer is that the geologist usually devotes his attention not to the discovery of individual deposits but to the determination of broad structural features and of the general relation of these features to the occurrence of the ores or minerals. He attempts to interpret the geologic history and structure of a region and to suggest where certain ores or minerals may or may not be found, but the details of the search for commercially valuable deposits are left for the man who is willing to spend time and labor in patient exploration at one spot.

Pioneer work on mineral deposits in a new field is as a rule done by the prospector. The geologist does not pose as a pioneer; he is not looking for bonanzas; he is in search of information that may be of wide general use and in the search he merely takes the larger ascertainable facts, studies their significance, and in his report groups them in an orderly way, so that even in his reconnaissance work he lays the foundation for thorough scientific study of the region he explores. For some of his purposes an old, abandoned mine without economic value may be of great service; it may show the manner in which valuable ores occur typically; it may show their mineral associations and mode of origin; it may indicate the kind of country rock that will probably contain deposits of a particular nature. On the other hand, his work may develop facts that seem to have no immediate practical application but that may in time—in a very short time perhaps—become of great economic importance.

An example of work of this class may be seen in some of the Geological Survey's explorations in Alaska. Most of the gold mining thus far done in that region has been confined to work in the placers. In the course of their explorations in this rough region the Government geologists have not only determined the geology of large areas and examined the streams or localities in which valuable placers are found or are likely to be found, but have endeavored to fix the place of origin of the placer gold. Many of the rocks from which the gold was derived will doubtless remain untouched until the placers have been exhausted, but when the placer deposits are gone the miner must necessarily turn to the original sources of the gold. Some lode mining has indeed already begun in Alaska and, in spite of the difficulty of access to the interior, there is no doubt that it can be carried on profitably. On the other hand, much of the geological work in Alaska has been of immediate practical value. The map work is of prime importance, and many of the geologists' judgments as to the probable location of rich placers have been borne out by subsequent mining.

The determination of the character of the rocks and of the geologic structure of a region may afford a means of indicating places or zones in which valuable orebodies occur—places that the ordinary prospector would not at first consider favorable. An example of this form of geologic inference is seen in a Government report on the Bisbee district of Arizona. In this district the explorations of the prospector confirmed at once the geologist's prediction that valuable ore would be found in a certain locality.

It must be acknowledged that the prospector of earlier days—the man of pick, shovel, and pan—had little help from the geologist, and that much prospecting in out-of-the-way corners of the earth must still be done in advance of geologic study. Yet the modern prospector fully appreciates the value of geologic work as enabling him to plan his search intelligently, to avoid wasting his efforts in unfavorable localities, and to begin his work where he has the best chance of success. Many a prospector who plods behind his laden burros over the desert carries a well-worn geologic map in his pocket. Much modern prospecting, moreover, is carried on by machinery and involves the expenditure of large sums with no certainty of return. It is in directing prospecting of this essentially modern character that the mining geologist has applied his knowledge with greatest success, for few such enterprises are now undertaken without his advice. It may be said, however, that chance will always remain a large factor in the search for some minerals and for some kinds of ore and this factor will always insure work for the prospector as well as for the geologist.

In his search the prospector naturally enough collects specimens of any odd-looking or uncommon mineral that he may be able to find and submits them to the geologist or mineralogist for examination. The miner, too, in his daily operations not only strikes new mineral deposits but discloses geologic facts and relations that were before unknown, and these the geologist gratefully notes and interprets. The geologist is not equipped with diamond-drill or steam-shovel, and in many regions he can observe only the natural exposures of the rocks; but the operations of the drill and shovel serve to increase his means of observation and to give his work greater value.

Notwithstanding the fact that prospecting is a distinct art, the special knowledge of the geologist and his habit of trained observation enable him at times to recognize the presence of valuable mineral deposits without going through the ordinary steps of prospecting. A geologist of the United States Geological Survey, for example, recently discovered and called attention to a valuable deposit of monazite in Idaho, which is now being exploited. Another discovered tin-bearing veins in Alaska. The Government geologist, of course, can reap no pecuniary benefit from such discoveries, for he is prohibited by law from acquiring any interest in mines or mineral deposits. During the last few years many geologists have left the Survey to accept positions with mining and exploring companies or firms at higher salaries than those paid by the Government.

Gold Deposits of Georgia

By E. K. Soper

Gold has long been known to exist in the Appalachian Mountains in a belt more or less continuous from Maine to Alabama, but only in the southern end of the belt, in Virginia, the Carolinas, Georgia, and Alabama have deposits of workable size been found. Probably the first important discovery of gold in the South was about 1799, when a nugget reported as weighing 17 pounds was discovered on the Reed plantation in Cabarrus county, North Caroline. Other large nuggets were found in the State about this time, and soon North Carolina became a regular producer, and for twenty-seven years yielded all the native gold coined in the United States. The total production up to 1827 was about $110,000.[1] In 1828 discoveries were reported from Georgia, and the year following South Carolina made its first shipment to the mint. Gold was first produced in Alabama in 1830. From this time on until late in the forties the output rapidly increased in all of these States, and they ranked as the greatest gold producers in the United States. The most active mining carried on in this region during these years was at Dahlonega in Lumpkin county, in the northeast corner of Georgia. By 1838 this district had attained such importance that the Government established a branch mint in the town of Dahlonega, and during the twenty-three years that elapsed between 1838 and 1861 (when the mint was closed) it coined gold to the value of $6,115,569. When the Civil War broke out mining in the South was generally abandoned, and since that period none of the districts have ever attained their former prosperity.

The principal gold deposits in Georgia occur in what is known as the Dahlonega gold belt, extending from the extreme northeastern corner of Georgia southwest to Haralson county in a fairly straight line. This belt varies between one and thirty miles in width and is about 150 miles long. That portion of the belt lying in Lumpkin and White counties, comprising the Dahlonega district, is the most important. The nearest railroad point is Gainsville, situated about twenty-one miles from Dahlonega on the main line of the Southern railroad. The topography of the district is typically that of the foothills on the eastern slopes of the southern Appalachians. Low rounded hills and broad gentle valleys are characteristic and the absence of sharp angles or ridges is striking. To the north, some fifteen miles, the Blue Ridge rises in striking contrast to the smooth and eroded hills below. The region is well watered and covered with a heavy growth of Georgia pine, chestnut, hickory, oak, and underbrush. The pines afford abundant and cheap timber for mining operations, while numerous streams or 'branches' furnish the power for the mines and mills. The Chestatee and Etowah rivers and their tributaries constitute the drainage system of the region.

The rocks of the Dahlonega region are Archean mica and hornblende gneisses and schists. The prevailing dip varies from 30 to 60°S.E., while the strike is about N.20 to 30°E. The gneisses and schists shade imperceptibly into each other, even in the same mass, and everywhere there is abundant evidence of intimate relationship between the two. The rocks are generally much contorted and banding in layers varying in width from 2 to 20 ft. is common. The formations are overlain by a mantle of saprolite derived from the weathering of the Archean crystallines themselves. This saprolite varies in thickness from 50 to 100 ft. and is of a red, yellow, or brown color, according to the degree of oxidation of the iron by which the color is imparted. While the saprolite usually retains the form and structure of its parent rocks as to contortion, banding, and folding, yet it is quite soft, and in places of cheese-like consistence. This fact has an important bearing on the original method of mining adopted throughout the district, as will be shown later. The gneisses and schists are rarely cut by granitic and dioritic intrusions, but very few granite dikes exist in the vicinity of Dahlonega. Pegmatite dikes occasionally occur. Northeast of Dahlonega, about one mile, is an outcrop of a quartzose foliated rock, different from the usual schists of the region and resembling more closely quartzose slate. The mica schists are sometimes garnetiferous and often enclose more or less well defined quartz veins. The various kinds of rock weather to different varieties of saprolite of characteristic colors. These are spoken of by the miners as the 'yellow' and 'black' belts. The yellow saprolite is probably derived from a pearl gray hydro-mica schist, and the black variety seems to be the weathering product of the dark hornblende schist and quartzose slate.

The gold deposits belong to a rather unusual type to which G. F. Becker[2] has given the name of 'stringer lead'. They consist of more or less parallel bands of gneisses and schists fissured and filled with gold-bearing quartz and sulphides. The small quartz bands are not true veins, but may be better described as an aggregate of numerous narrow and discontinuous quartz lenses and stringers, occuring in a zone, and which taken altogether form a 'vein'. The thickness of the veins varies from a few inches up to twenty feet. They pitch usually to the northeast. In addition to these belts of discontinuous quartz lenses, the schist within the zone of fissuring is often itself auriferous. Especially is this true toward the surface in the saprolite belt, where the silica has been removed to a large extent in solution, leaving the gold behind. Among the miners there is the general opinion, based on observations and experience in the district, that in the yellow saprolite, gold may be present throughout the mass; while in the 'black belt' the gold is confined to the unaltered quartz stringers that are found to have resisted the agencies of weathering and decomposition. While this is not to be taken as an invariable rule, there is certainly a strong tendency for a more uniform distribution of the gold throughout the 'yellow belt'. Concerning the age of the veins, there is con-

[1] 'Gold Deposits of Georgia.' Yeates, McCallie, and King. Geol. Surv. of Georgia, 1896.

[2] 'Gold Fields of the Southern Appalachians'. U. S. Geol. Surv. 16th Ann. Rep., part III, pp. 251-331, 1895.

siderable doubt. Various geologists have reckoned their origin as dating from pre-Cambrian to late Cretaceous time. Evidence would seem to point toward an ancient origin. The rocks in which the veins occur are Archean; the entire region has suffered a tremendous amount of erosion and denudation, and we have only the roots of the original veins remaining. The eroded material has gone largely to make up the rich and extensive deposits of auriferous gravels which furnished the bulk of the gold in the early days of the district. One thing is certain; fissuring occurred subsequent to the shearing of the schists. The chief evidence supporting this conclusion is the inclusion of fragments of the schist within the quartz. The opinion is sometimes expressed regarding these deposits, that they may be expected to increase in value with depth. This is a risky statement to make regarding any gold-quartz vein, but from the evidence at hand, it is altogether unlikely in the Dahlonega region.

The character of the ore varies greatly, not only among the various deposits in the district, but within the same vein. The filling consists essentially of quartz, pyrite, some chalcopyrite, and free gold. Little pyrite occurs above water-level. The quartz, where not stained from the oxidation of the pyrite, is usually milky white in color. In the saprolite zone the gold is often rusty, and much was lost on this account during the early days of hydraulic operations. It is almost impossible to state an average value of the ore on account of the pockety nature of the deposits. Perhaps $1 to $5 per ton would cover the larger deposits as they exist today. While the deposits have not the form and well defined walls of 'true fissure' veins, their origin has been similar. Mineralization is probably due to heated ascending solution through zones or belts of fissuring in the schists. The impregnations in the schists are due probably to even shattering of the homogeneous rock, and subsequent leaching out of the quartz, for no evidence of replacement has been observed.

The early methods of mining in Georgia, as well as in the neighboring States in the Southern Appalachians, consisted of panning and sluicing with the aid of the long-tom and rocker. Gradually, as the large deposits of decomposed saprolite ores became recognized, hydraulic methods were applied with great success, and this led to a mining and milling system peculiar to the region. The belts of yellow saprolite in the Dahlonega region were hydraulicked in the same manner that gravel banks are mined today in many localities, and the auriferous material was conducted through ground and wooden sluices to the mill, where it passed over coarse grates or screens into a bin with a perforated bottom. The holes in the bottom of the bin were from ½ to 1 in. diam. All of the material passing through these holes was run to waste into the neighboring stream which usually supplied the power to run the mill. It has been estimated that 50% of the gold was lost in this way. Of the remaining 50%, one-third was caught in the sluices. The material in the bin was fed by hand into the mortars, as it was found that mechanical feeding was not successful on account of the extensive variation in the hardness of the ore with its soft saprolite and chunks of solid quartz. The stamps were designed for coarse rapid crushing, and from this crude but profitable practice was evolved the so-called 'Dahlonega type', or 'Hall type' battery.

A large number of mills were in operation up to as late as 1895, and a considerable number are working today, although practically all of the saprolite ore is now exhausted. The Hall type battery consists of five 450-lb. stamps with a 9-in. drop, averaging 90 drops per minute. Round-punched screens are used with 120 holes per square inch. The height of discharge is 2 in. when the dies are new. The cost of a 10-stamp battery of this type complete and set up at the mine near Dahlonega has been given as $2350.[3] They give an extreme of rapid crushing, but with the gradual exhaustion of the soft saprolite ores, and the finding of hard quartz-pyrite ores at depth, the Hall type batteries are no longer so efficient, and many have shut down. With the passing in depth to a hard ore, there is also usually a marked decrease in grade, so that the situation that now confronts many properties is serious. In the days when hydraulic operations were at their height, saprolites running as low as 40c. per ton were worked at a profit.

The total average cost of mining and milling under favorable conditions by the Dahlonega method varies from 18 to 25c. per ton. As to the grade of pyritiferous quartz ore that can be worked at a profit by underground methods, it is hard to say, for much depends on factors that are variable in the district, such as labor, water-power, and location. The cost of underground mining at the Lockhart mine on Yahoola creek is given at $1.35 per ton, including milling. Conditions here are more favorable than at many of the properties. Underhand stoping is in use, and the roof supported by stulls 6 ft. apart. Labor is almost entirely white, but is nevertheless very inefficient. Wages range at many of the smaller mines from 90c. to $1.75 per shift, with perhaps an average of $1.25. While the best ore of the district is certainly worked out, and little unworked saprolite ground remains, there are doubtless properties that can be made to pay good profits with economical management and suitable methods of milling. However, none of the Georgia ores are high grade, and it is to the larger low-grade deposits that the region must look in the future.

Nitrate produced in the different Chilean Pampas is given by the Asociación Salitrera de Propaganda, in quintals, as follows, during the eight months ended February 28, 1909 and 1910:

Place of production.	1909.	1910.
Tarapacu	13,033,790	16,756,891
Tocopilla	2,104,400	4,167,020
Antofagasta	5,407,899	6,843,385
Aguas Blancas	2,568,805	2,595,640
Taltal	3,838,832	4,349,547
Total	26,953,726	34,712,483

LAKE VIEW GUSHER

The great oil well shown in the accompanying picture is situated in the Midway field of the McKittrick-Sunset district, in Kern county, California. It is the property of the Lake View Oil Co., of which the Union Oil Co. owns 51% of the stock. The flow of oil was found March 15 at a depth of 2265 ft., and for a long time the well resisted all attempts at control. It began flowing at a rate estimated at 47,000 bbl. per day and is thought to have attained a maximum of 90,000 bbl. at one time. Its present flow is conservatively estimated at 25,000 bbl., and, as one of the illustrations show, even this amount of oil resembles more the flow of water in an irrigating ditch than an ordinary stream of oil. While there has been some waste, most of the oil has been caught in open reservoirs or ponds and is being saved. The total flow so far is something over 3,000,000 bbl., and the well has surpassed all known records for output in the same time. The Lucas well at Beaumont, Texas, produced more oil in a single day, but the life of the well was short. The production of the State for May has been unofficially estimated at 7,000,000 bbl., which is the highest since production began. The yield has reached proportions which are far in excess of the facilities for moving the oil to the markets, and there is such congestion at the wells and at storage and transporting points that either the production must be diminished or a larger movement and storing capacity be obtained. These matters are now interesting the operators and producers, and it is safe to say that before the end of this year the facilities for storing, piping, and financing the oil will have been vastly increased, although it will probably take several years before they will care for the output at its present rate of expansion, which will be heavily swelled by the bringing in of numerous new wells, including many big gushers. In April 6,580,510 bbl. were produced. Stocks on hand March 31, 1910, were 19,569,085 bbl. Consumption in April was 6,445,243 barrels.

Progress in Ore Treatment at Kalgoorlie

By M. W. von Bernewitz

*The metallurgical practice at Kalgoorlie, though only extending over a period of sixteen years, has made great strides. In 1893, the only means of obtaining gold from the surface alluvium and quartz veins near Hannan's was by the aid of the 'shaker' and 'dolly pot'. Early in 1849 the MacClay brothers erected a unit mill at the Kalgurli mine, the tailing from which ore is said to have assayed £40 per ton. Then five stamps were erected at the Croesus mine. In 1895 the lode formations in which the prospectors had found 'mustard gold' on the Lake View Consols mine had been shown to be of sufficient value to warrant the erection of a plant. An Austral Otis ball-mill was put up, but, not proving a success, was replaced by 10 stamps, which were erected in the gully between the Lake View Consols and the Great Boulder Proprietary Co.'s mines. Although not actually the first mill here, it may be considered the starting point of the metallurgical practice at Kalgoorlie. The ore was hand-fed, amalgamated in the mortar and on copper plates, passed over blanket tables into pits, the slime overflowing and running into ponds, while the sand in the pits was dug out and wheeled away for future treatment. During this time good ore had been found in a number of other mines, and several 3 and 5-stamp batteries were erected, but with the same primitive arrangements.

The Huntington mill was introduced about this time, the Associated Gold Mines, Ltd., being the first, with three mills; then the Hannan's Oroya and Hannan's Proprietary built each a similar number. Over 100 tons per day was crushed by each plant of three mills. The sand and slime was stacked or run into ponds. The Oroya dump at present is being treated by a vacuum plant, while the treatment of that of the Proprietary is under consideration. A point worthy of note in the Huntington milling is the low percentage of gold in the slime, as compared with the sand. The high value of the tailing from the different mills was by this time worrying not only those who had plants at work, but also those who contemplated erecting them. The original dry-crushing plant was erected on the Brownhill, and an electro-amalgamation process, called the Hayeraft, was put up near the Hannan's Lake; but neither of these was a success. The Great Boulder Proprietary G. M., Ltd., erected 30 light slow-running stamps, the tailing after passing over copper plates being treated in grinding pans, which increased the extraction, but still left considerable gold in the sand and slime. These were stacked and subsequently treated. The Ivanhoe increased its battery to 60 head of 950-lb. stamps, gear-driven cam-shafts with clutch arrangement.

One of the directors of the Lake View Consols visited Broken Hill about this time, and saw the work at the Broken Hill Proprietary mine, and, recognizing the advantage of having a trained metallurgical chemist and assayer, persuaded the chief assayer of the Proprietary company to come to Kalgoorlie. Experiments of treatment of tailing by cyanide were begun, and by the end of 1896 the accumulated dumps on the Lake View mine were being treated. The slime difficulty next arose. The gold in this product was found to dissolve in the cyanide when agitated, but the trouble was to get the gold solution out of the slime. After numerous experiments, the adapted sugar press was found to be the best filtering medium. Early in 1897 the satisfactory working of the filter-press made great advance in the treatment of Kalgoorlie ore possible. The method of treating the slime by cyanide in the press was found to be too slow, and agitation and subsequent filter-pressing was adopted. The Brown Hill Co., Ltd., erected its second dry-crushing plant for the treatment of its oxidized ore. This consisted of a rock breaker, two revolving dryers, several No. 5 Krupp ball-mills, the crushed ore being separated into fine and coarse products by an air current, the sand being elevated to steel vats for percolation treatment by cyanide, and the slime being mixed with solution, agitated in small vats in sieves—one slightly below the other; and finally treated in filter-presses. This process was not the success that was anticipated, and the residue has since been re-treated. The oxidized ores in the mines cut out at a comparatively shallow depth, and the sulphides made their appearance at this point, so there was more trouble ahead for the millmen.

Soon after the sulphides appeared, telluride of gold was identified on Block 45 lease. It was also found in all of the other mines, and bonanzas of exceedingly rich ore were struck. This ore could not be treated locally at that time, so it was shipped to the smelters at Dapto, Wallaroo, and Fremantle, by the Lake View Consols, Associated, Golden Horseshoe, Kalgurli, Perseverance, and Associated Northern mines. The freight and smelting charges were high, fully five times the present cost of mining and treating a ton of ore. The Golden Horseshoe Estates, Ltd., erected a small blast-furnace at the mine, and the smelting of rich ore was continued for some time.

Some time during 1897, a seven-hearth roasting furnace was erected on the Great Boulder Main Reef, this furnace being similar to those used at the Mt. Morgan mine in Queensland. It was rabbled by hand, but costs were high and the roasting poor. It may be mentioned here that the ores of most of the mines are practically dry, and suitable for dry crushing. The ore at the Main Reef was crushed by a Gates breaker followed by Krupp No. 5 mills, and then went to the furnace. Later on, the Lake View Consols and South Kalgurli erected 'Brown straight-line' furnaces, followed by the Kalgurli and Associated with the Ropp type. At these mills the partly roasted ore—for these furnaces did very poor work—was cooled in various ways, and then damped down with strong cyanide solution. This ore was then elevated to vats to be treated with solution by the percolation method. This process was a great failure, and metallurgists were at a loss to understand why this was so for some time, until the chemical

*Abstracted from 'The Gold Mines of Western Australia'.

reactions during roasting and cyaniding became fully understood. In roasting, the lime and magnesia in the ore are converted into sulphates, and these, on being wetted by the solution in the vats, set hard, so that in several instances the half-treated ore was removed from the vats by picks and bars. The ore was under treatment for periods up to a month with low extraction and high consumption of cyanide. This clearly would not do, so grinding pans were installed on the Great Boulder Main Reef, the idea being to slime all the ore. The process was to dry-crush, roast, mix the ore with salt water, grind, and amalgamate in pans, force the slime into presses and filter out the water, the slime being then mixed with cyanide solution and pressed again. This was probably the first time the press was used on roasted ore. The Lake View Consols and Associated companies remodelled their plants on these lines, their system being to break the ore in Gates crushers and Rodgers rolls, crush in Krupp mills, roast in Brown and Ropp furnaces, mix with cyanide, agitate, and then treat in the presses. The Kalgurli had a Ropp, the roasted product being separated, the slime being air agitated and pressed, while the sand was treated in vats for some weeks with cyanide solution circulated by means of small air-lifts. At the Associated mill, and possibly some of the others, Wilfley tables were being worked to catch the unroasted pyrite that came from the furnaces, this in itself showing what sort of work the furnaces were doing. The Kalgurli had Halley percussion tables for the same purpose, the concentrate being afterward ground in a pan. The rabble carriages in the Associated roasters used to carry raw ore from the feed to the discharge end and drop it there to mix with the roasted ore. This went on for some time.

The Great Boulder Perseverance had in the meantime erected a large dry-crushing plant, using Griffin mills and the Holtoff-Wethey furnace. This type was also a poor roaster. The Koneman de-sulphurizing process was tried on the Great Boulder. Roughly, it consisted of roasting the ore in lump form in a furnace of three compartments, the ore falling into an increasing heat to be thoroughly oxidized. The roasted ore was to be crushed in a machine patented by Mr. Koneman. The process was not a success.

In the dry-crushing mills it was apparent that something must be done to improve the roasting and subsequent treatment. In the case of the Lake View Consols, the plant was shut down, and the treatment of the ore was continued in a stamp battery. About this time the Edwards—and later on the Merton—furnace from Victoria was introduced, and the seven hearth at the Main Reef, the Brown at the South Kalgurli, the Ropps on the Kalgurli and Associated were thrown out, and the newest types of mechanical furnaces were erected. The Great Boulder and the Perseverance later on converted the Holtoff-Wetheys into the Edward type. From this time onward the roasting was good. The roasting problem being settled, the treatment of the roasted ore was the next question, and with few differences the treatment on the Associated, Associated Northern, Great Boulder, Kalgurli, Main Reef, Perseverance, and South Kalgurli settled down to the following: (1) breaking the ore in Gates or Blake crushers; (2) milling in Krupp or Griffin mills; (3) roasting in Edwards or Merton furnaces; (4) cooling the roasted ore; (5) mixing with weak cyanide solution; (6) classication, the sand being ground in pans and the coarse gold amalgamated; (7) thickening the slime from all sources and running it into agitators; (8) treating with cyanide from 2 to 12 hours; (9) finally filter-pressing, the residue being disposed of in various ways.

Before adopting this scheme, the South Kalgurli installed the Reicken process. Its principle was as follows: The roasted ore from the Brown furnace was cooled, mixed with cyanide and agitated. It was then run into Reicken vats, which had sloping sides and a curved bottom, a horizontal shaft with arms attached keeping the pulp in motion. The sides of the vat were lined with copper plates, which served as the cathode, and iron bars suspended in the vat acted as the anode. An electric current of low voltage was used. A constant stream of mercury was made to flow over the copper plates, thus keeping them bright. The gold from the cyanide solution was precipitated on the plates as amalgam, as was also coarse free gold in the pulp. When it had been treated for 12 hours it was discharged into agitators and filter-pressed. This process was also used by the Great Boulder No. 1 company for a time, but it was a failure at both mills, its weak point being very prominent.

In the wet-crushing mills the necessity of close concentration, in order to separate the pyrite from the ore, was early apparent. All kinds of concentrators were tried, but the Wilfley table did the best work, and is installed in all the wet mills now. Canvas was also used to recover the fine material, but still some got away with the pulp. It was found that the Wilfley tables did better work if given a certain feed, so the plan of preliminary separation of the stamp pulp into grades was adopted. In treatment of the concentrate attempts were made to cyanide this product direct in vats, but with poor results. Then it was shipped to smelters, but this was too expensive. Lastly, the roasting of concentrate in Edwards or Merton furnaces, fine grinding and amalgamating in pans, agitation with cyanide and filter-pressing was tried, and this is the treatment to this day. The pulp from the Wilfley tables was at first pumped up to collecting vats. Here, the sand settled, and was given a short cyanide treatment, then dropped into other vats for a few days' more treatment. The slime overflowing from the collecting vats was thickened, agitated with cyanide, and filter-pressed. This process was greatly in advance of previous efforts, but extraction was still only fair. Something was wanting. Very fine concentrate and telluride escaped with the pulp. The finer grinding of the pulp from the tables was then tried at the Hannan's Star in a tube-mill, this being the first tube-mill used in the world in grinding gold-bearing ores. At the same time bromo-cyanide was tried. In this chemical, tellurides are soluble, though not in plain cyanide; and there is no doubt that the tellurides escaping were partly responsible for the low results in the earlier treatment with cyanide. At the Han-

nan's Star, where bromo-cyanide was first used in 1899-1900, the plant had ball-mills, the dry-crushed ore being mixed with water or solution previous to rough classification and fine grinding.

The Lake View Consols followed in 1901 in using bromo-cyanide in its mill, after all the pulp had been ground fine, the agitated slime being filter-pressed. About the same time the Brown Hill followed with the same treatment. These were the first instances of all-sliming in wet mills. Later on the Golden Horseshoe and the Ivanhoe adopted finer grinding. In the new mill of the former the process was all-sliming with tube-mills, and at the latter partly sliming in pans, and treatment of sand and slime still continues. At the Hainault also the latter system is in vogue. At present the Lake View Consols uses tube-mills alone, and the Oroya-Brownhill and Golden Horseshoe use pans and tube-mills in series with subsequent treatment of the slime with bromo-cyanide. The Ivanhoe uses bromo on its slime only.

Improvements in the filter-press were rapid until 1899, and the press used now is practically as it was in that year. These were hand-screwed, the hydraulic closing type being worked later at the Great Boulder, Ivanhoe, and Brown Hill. The first little press experimented with is still at the Lake View. It should be preserved, and so that it may be shown to interested mining men and visitors as the forerunner of the machine that has done so much for ore treatment. The presses were first charged by pressure tanks; but pumps were afterward tried, and are now universially used. The vacuum process of treating slime became fashionable in America some five years ago and was tried here experimentally. The only serious competitor of the press up to 1908 was the mechanical vacuum plant on the Great Boulder, but in 1908 and 1909 vacuum plants were erected on the Lake View Consols and Oroya-Brownhill to retreat the residue from those mines. The vacuum plant is cheaper in first cost than the filter-press plant, but its efficiency has not been proved superior. Experiments are now underway with the press, the idea being the discharge of the slime by sluicing without opening up. It will be interesting to note the improvements effected in these two types of filters, and the survival of the fittest.

The disposal of residue has been an interesting subject from the start of milling on a big scale. The various systems may be put down as, hand and horse trucking, electric locomotives, belt conveyors, elevators and swinging booms, and, lastly, the sluicing away to ponds. The difference in the cost of each method is not much, and in this windy place high dumps have been a curse to the engineers, workers, and inhabitants of the belt. Of course, where the residue needed re-treatment it had to be stacked near the mills.

In the recovery of the gold from the cyanide solutions there has been a certain amount of trouble at times, but on the whole the precipitation on zinc shavings has been good. In the clean-up the lead-lined press for filtering the sludge from the acid tank was first used here, as was also the tilting furnace for the smelting of the roasted sludge with the usual fluxes.

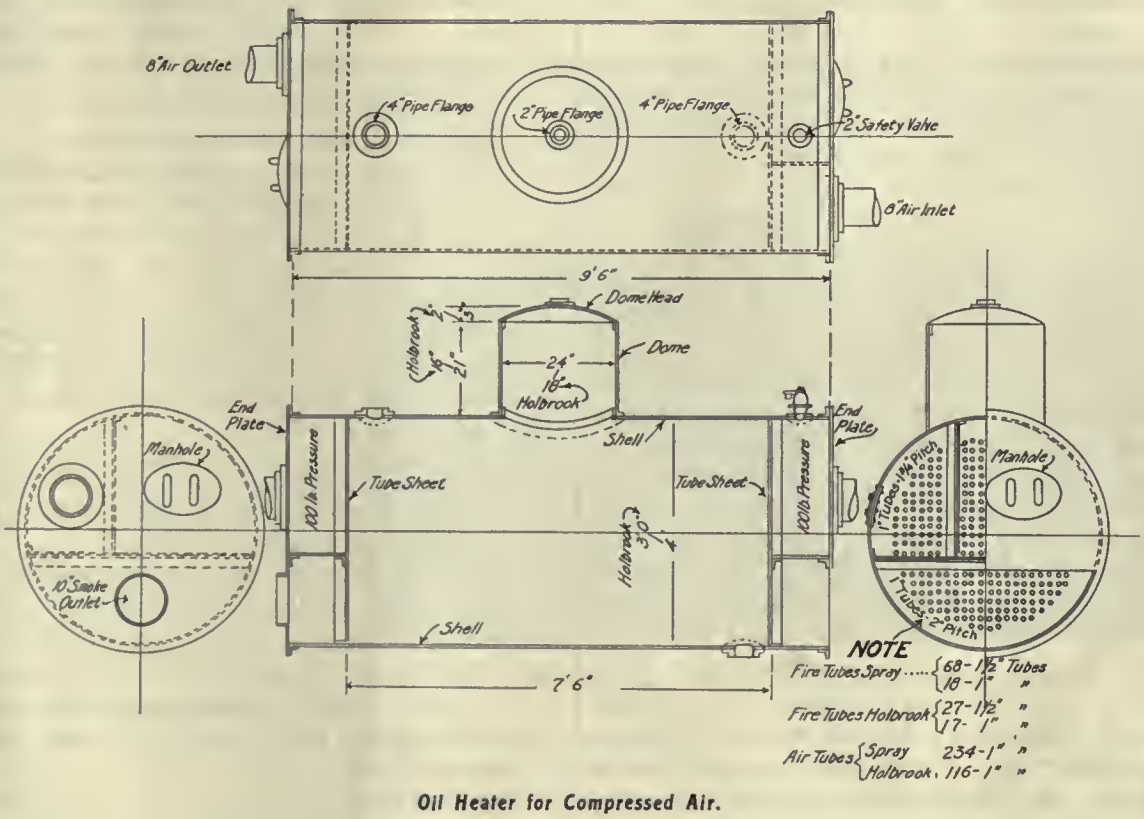
On thing not to be forgotten in this review is the water supply for the mills. Until 1903 the supply consisted of salt water procured from some of the mines. This was not good for general work, and it was very destructive to machinery. The Coolgardie Goldfields Water Scheme was completed in 1903, and since then an abundant supply has been available. There is no doubt that if the mines had to depend upon the salt and rain water conserved in ponds, mining and treatment would not be half as large. This is no place to go into details of cost of treatment, but it may be said that in the days of shipments of ore to smelters the cost was as high as £6 per ton, whereas the present cost, 10s. 6d. per ton, may be considered a fair average for wet and dry-crushing mills. It is probable that costs are on bedrock. Extraction varies, but may be averaged at 91% in both wet and dry mills. The following questions are still debatable on this field: breaking the ore in Gates or Blake crushers: milling in Krupp or Griffin mills; roasting in Edwards or Merton furnaces; fine grinding in pans or tube-mills; agitating in air, A. Z., or ordinary agitators: filtering the solutions from the pulp in presses or vacuum plants: disposal of residue by belts or sluicing; and, finally one that has lately been suggested, namely, the efficiency and economical working of the Krupp mill—wet crushing—as against the modern heavy stamp.

In the above review, necessarily somewhat incomplete, I had the assistance of C. M. Harris, manager of the Hannans Proprietary, Ltd., and local secretary of the Australasian Institute of Mining Engineers, who furnished the history of ore treatment from 1893 to 1897, and revised this article. My own observations and experience date from thence onward, especially in the latter part of 1899 and in 1900.

'Patents and Industrial Progress' was discussed trenchantly by William Macomber in the June number of *The North American Review*. He shows that there are two demands which our industrial and scientific interests make upon our patent system. These are: (1) The grant of a patent should afford substantial ground for assuming that the thing patented is novel and that the patent is valid. (2) The means for determining the novelty and validity of a patent —the final, judicial determination of these questions —should be certain, speedy and inexpensive. The remedies to meet the first demand are: (1) To allow the commissioner to use the surplus the Patent Office has earned to erect and equip a plant adequate to the needs of the business. (2) To co-operate with him in a revision of the fee schedule to materially increase the revenues without additional cost to the patentee. (3) To allow him to use the earnings of his department to make the work efficient. And the remedy for the second is the establishment of a Court of Patent Appeals, to which should be given final appellate jurisdiction. This court should be composed of five judges, all of them trained in the patent law. The method of appeal should be by case and exceptions; the record made by counsel and settled before the patent judge who heard the case, to the end that the present enormous cost of printing may be reduced and that the Appellate Court may not be burdened with a padded and cumbersome record.

OIL HEATER FOR COMPRESSED AIR

The efficiency obtained by re-heating compressed air is well understood. In re-heating, however, it is important to secure uniformity of temperature, and this is difficult to maintain when the heat is applied directly by passing the gases from the burning of fuel around coils or chambers through which the air circulates. The accompanying illustration shows a most efficient and economical heater, designed by Gerald Sherman, superintendent of the mining department of the Copper Queen Consolidated Co., at Bisbee, Arizona, and erected by him at the Holbrook shaft. In this heater a heavy oil is employed as a medium to transmit heat to the air-pipes, which latter pass through the oil-container. This oil is a residue from the partial distillation of the lighter compounds from crude petroleum, the residue having a gravity of about 12° Beaumé, and a flash-point of 700. The heater consists of a boiler 7 ft. 6 in. long by 4 ft. diam., provided with a dome which is open to the atmosphere. An 8-in. air-pipe admits the compressed air to a chamber at the rear lower side of the boiler, from which it is conducted through 1-in. tubes which make two turns within the boiler, causing the air to travel three times the length of the container in contact with the oil. One large flue, 10 in. diam., also passes through the lower part of the boiler for the heated gases. The boiler is set in brick-work in the ordinary way, the grate extending the full length from front to back. On this grate a coke fire is maintained, which raises the temperature of the oil to about 335°F., although it can be brought to 360°. Coke at Bisbee costs $10 per ton, and the amount consumed in re-heating the air does not exceed 400 lb. per day. The temperature of the air as delivered to the hoisting engine is usually about 315°F., and the temperature of the exhaust is from 32 to 40°. In a 27-minute test the consumption of free air per shaft horse-power was 24.4 cu. ft. Another test of 40 minutes' duration with air at a temperature of 355° showed a consumption of 28.7 cu. ft. of free air per shaft horse-power. The total work done in this test was 58,441,980 foot pounds, or a total shaft horse-power of 1771. Approximately 75 lb. of steam at the power-house equalled one shaft horse-power at the hoist. In this test the weight hoisted was weighed, and allowance was made for rope-friction and all losses. These re-heaters are being installed at the several subsidiary shafts of the Copper Queen, and hoisting by air will be used exclusively. It is found that the economy is greater than by transmitting electric current for this purpose.



Oil Heater for Compressed Air.

Land has been proclaimed by the President as available for settlement to the amount of 11,196 acres in the Gunnison forest, 5640 in the Cochetopa forest, and 45,489 in the Uncompahgre forest, in Colorado. The Secretary of the Interior has designated for homesteads 875,000 acres in Wyoming and nearly 4000 in Colorado. Thus land found available for settlement is being steadily taken out of the National Forests as fast as it is classified.

Chilean shipments of nitrate to the United States during 1909, according to the report of Alfred A. Winslow, United States Consul at Valparaiso, were valued at $18,769,236, against $14,765,250 in 1908, and $16,899,723 in 1907. The basic value of the importations of Chilean nitrate of soda into the United States last year, according to customs statistics, was about $31 per long ton, against $36.50 in 1908, and $40 in 1907.

The United States Government purchases annually from $6,500,000 to $7,000,000 worth of fuel. This sum includes the cost of delivery and stowage.

Atomic Weight of Chlorine

By F. H. Mason

Except in those few instances where the final weighing is made of the element itself, the accuracy of analytical chemistry depends upon the precise determination of the atomic weights of the elements, and, as the average analyst has neither the time nor the appliances to carry out these determinations himself, he must look to those savants who, from a pure love of science, and often aided by grants from governments and scientific societies, make these investigations for him. Each year a committee, consisting of eminent chemists from the principal commercial nations of the world, investigates researches that have been made during the year, and assign to each element the atomic weight that shall be used by analysts during the ensuing year, thus uniform results may be expected in all parts of the world. Notwithstanding this, should even a small error occur in the atomic weight of an expensive substance, it might cause an extensive loss to either the buyer or the seller.

In the October 1909 issue of *The Journal of the Chemical Society* there was an account of a most elaborate research, conducted by Robert Whytlaw Gray and Frank Playfair Burt, on the atomic weight of chlorine, and since the atomic weight of this element is the fundamental rock upon which the atomic weights of a large number of the other elements rest, it is highly important that it should be known with the greatest possible degree of precision. It was with this view that Gray and Burt, aided by a grant from the Royal Society, undertook the work. They attacked the problem from a physico-chemical standpoint that consisted of a detailed study of hydrogen chloride comprising: (1) A revision of the density of the gas. (2) Its volumetric analysis. (3) The determination of the form of the *pv* isothermal at 0 degree and between pressure limits of 780 and 150 mm. The hydrogen chloride used in the experiments was prepared by three methods: (1) From sulphuric acid and sodium chloride. (2) From sulphuric acid and ammonium chloride. (3) From silicon tetrachloride and water.

The following are the mean of the results obtained from determinations of density of the gas from three different sources:

Source of gas.	Weight of 1 litre of gas at 0 and 760 mm. in London corrected for compressibility of HCl.	Deviation from mean + or —
H_2SO_4 and NaCl	1.64016	0.00010
H_2SO_4 and NH_4Cl	1.64023	0.00008
$SiCl_4$ and H_2O	1.64016	0.00008

In the first series, four determinations were made, in the second, seven, and in the third, ten. The final mean calculated by the method of least squares is 1.64011 ± 0.00005, and the weight of a normal litre of gas is $\frac{1.64011}{1.000588} = 1.63915$ gram

where 1.000588 is the factor that expresses the difference in the value of *g* between London and Lat. 45 degrees.

In the tests based on determination of the volumetric analysis of hydrogen chloride, the mean result of eight experiments gave the figure 1.0079 with a probable error ± 0.000017.

If D(HCl) represents the weight of a litre of hydrogen chloride at 0 degree and 760 mm., Lat. 45 degrees, and D(H) represents the weight of a litre of hydrogen under the same conditions, and if the ratio of the volumes of hydrogen and hydrogen chloride, which at 0 degree and 760 mm. contain an equal number of molecules, is denoted by R, then the molecular weight of the gas in terms of O = 16 is given by the expression

$\left\{\frac{D(HCl)}{D(H)} \cdot \frac{2}{R}\right\}$ Atomic weight of hydrogen chloride.

Taking Morley's values for both standard litre of hydrogen and also for the atomic weight of that element the molecular weight of hydrogen chloride is

$$\frac{1.63915}{0.089873} \cdot \frac{2}{1.0079} \cdot 1.00762 = 36.467$$

and the atomic weight of chlorine 35.459.

In the method of determination of the form of the *pv* isothermal at 0 degree, and between the pressure limits 780 and 150 mm. it was found from a large number of experiments, in which every care was taken to eliminate errors and in which corrections were made that the limiting density of oxygen was 1.42762 and that of hydrogen chloride 1.62698, the molecular weight of hydrogen chloride, therefore, in terms of oxygen is:

$$\frac{\text{Limiting density HCl}}{\text{Limiting density O}} \cdot 32 = \frac{1.62698 \times 32}{1.42762} = 36.469$$

and the atomic weight of chlorine 36.469 − 1.0076 (atomic weight of hydrogen) = 35.461.

Gray and Burt finally take the figure 35.46, being the mean of the results they obtained by the two different methods, as the atomic weight of chlorine. The following are the results of recent researches on the atomic weight of chlorine, and the mean of them gives a figure that coincides with that obtained by Gray and Burt.

Dixon and Edgar	35.463
Edgar	35.461
Noyes and Weber	35.452
Richards	35.457
Guye and Ter-Gazarian	35.461
Guye and Fluss	35.466

Tennessee Copper Co. dividends are becoming more and more irregular. The current year is nearly half gone, and the stockholders have thus far received no income from their shares; neither is the management planning a disbursement in the near future. Last December the company paid $1.25 per share, which was the first distribution since September, 1908. The addition to the sulphuric acid plant is now about three-quarters completed at present. The company is producing sulphuric acid in the first unit of this plant at the rate of 75,000 tons per year; although its capacity is well over 100,000 tons. Last year there was derived a profit of $83,000 from acid sales. The mine is stated to have more ore in sight than at any previous time. The reserves at the end of its fiscal year were 4,172,311 tons. The yield of copper per ton, however, has not gained, but rather lost, the average being about 32 lb. as compared with 34 lb. in 1901; in 1903 the yield ran up to 37.61 lb., and dropped to 30.38 lb. in 1908.—*Boston News Bureau.*

Faulting in the Bullfrog District, Nevada

By W. H. Emmons and G. H. Garrey

*The displacement of strata on one side of a fissure with reference to those on the other side is called a fault. Most fault fissures are inclined and the vertical angle by which a fault-plane departs from a horizontal plane is called the dip. The direction of a horizontal line in the fault-plane is the 'strike' of the fault. When the hanging wall appears to have dropped with reference to the foot-wall the fault is a 'normal' fault, and when the foot-wall appears to have dropped with respect to the hanging wall the fault is 'reverse'. All the faults in the Bullfrog district, so far as known, may be classed as normal faults. Many faults are marked by slickensides, which are smooth polished surfaces resulting from movement along the fault-plane. The slickensided surfaces as a rule are scratched or striated by the grooving action of harder particles or projecting points as one wall moves upon the other. These striae show the direction of relative movement of the walls. A 'fault-zone' consists of two or more nearly parallel fault-fissures with thin sheets of country rock between them. In places intersecting fractures connect the main fissures and these cross-fractures may be so numerous that the rock in the fault-zone is much fractured or is crushed. As a rule the structure is expressed by vertical sections, taken where exposures are best and rarely at right angles to the strike of all the faults shown. Sections used in text-books to illustrate the elements of faulting are, as a rule, drawn at right angles to the strike of the fault-plane.

Fig. 1. Fault on South Side of Hill South of Sawtooth Mountain.

In the study of the structure of tilted beds that have been faulted three sets of planes are to be considered: (1) the top or base of a bed or some similar horizon; (2) the plane of the fault; and (3) the plane of the section under discussion. Where the bed is faulted by a straight fault-plane there are two lines of intersection formed by the fault-plane and the upper or lower surfaces of the separated portions of the bed. Ordinarily these two lines are approximately parallel. Unless the strike of the fault is the same as the strike of the beds the two lines of intersection between the upper or lower surface of the bed and the fault are inclined to a horizontal plane. Sections drawn across the strike of the fault cut these lines at two points which may be used as datum points from which the apparent horizontal, vertical, and inclined elements of a fault, as shown in the section, are calculated. The position of these two points with respect to each other is different in vertical sections drawn in different directions through the same fault. It is convenient to have terms that apply only to a given section under discussion, without reference to a plane at right angles to the fault-plane and without regard to the origin of the fault movement. This will be accomplished by prefixing the adjective 'apparent' to the names of various elements. Description of what may be called the geometry of faulting is thus kept distinct from inference as to the cause of the movements.

'Apparent vertical displacement' is used here to designate the vertical distance between or the difference in elevation of two points that are the intersections of the two separated portions of a bedding or similar datum plane with the fault and that are in the plane of a vertical section chosen at random. The term 'apparent horizontal displacement' is used to designate the horizontal distance between the intersections of two faulted parts of a bedding or similar plane with the fault-plane, in any vertical section. Similarly, the distance between the faulted edges of a datum plane, measured along the line common to the plane of the fault and the plane of a section under discussion, may be called the 'apparent throw' and will coincide with the real throw only when the section described makes a right angle with the fault-plane.

According to Spurr,[2] "offset may be used to designate the perpendicular distance between the intersection of corresponding planes in the two parts of any faulted body with a horizontal plane, such as the earth's surface may be considered to be, the planes being projected for the purpose of measurement if necessary." Where such a projection is necessary the parts of the planes are said to be offset with 'gap', and where a line representing the offset intersects a faulted stratum or other datum plane at two places without such projection of the bed the stratum is said to be offset with 'overlap'.

The original attitude of sedimentary rocks is hori-

*Abstract from Bull. 407, U. S. Geol. Surv.

[1]"Geology of Aspen Mining District, Calorado', Mon. U. S. Geol. Surv., vol. 31, 1898, p. 251.

[2]Op. cit., p. 162.

zontal or nearly so. If water-stratified rocks are laid down upon a steep slope the thickness of the bed will vary and the base may have a steep inclination, but the bedding planes will in most cases be approximately horizontal. Similarly, a molten lava flowing over a surface first fills the deepest places and consequently is thickest there. Most of the lava-flows here described are of nearly uniform thickness and hence flowed on a nearly level surface. Where a lava is highly viscous a considerable initial inclination of the upper surface of the flow may also result, and, consequently, this surface may dip steeply even when it has not been deformed by movement; but in that case the thickness of the flow usually varies greatly. Lava moves while it is cooling, and before it solidifies may become highly viscous and thus develop flow-lines which are steeply inclined when solidification takes place. Accordingly, flow-lines do not show the original attitude of the lava beds and cannot be depended on for measurement of dip and strike, but the dip and strike may be safely measured on the bedding planes of water-laid tuffs between the flows, or along contacts between basalts and rhyolites of comparatively uniform thickness or between rhyolites of different color or composition. The occurrence of the brown contact glass at the base of several of the rhyolites in the area here discussed is of great assistance in determining the attitude of the flows.

In many of the mountains of the Bullfrog district, especially when viewed from the south, the flows may be observed dipping below the surface at steep angles. Owing to the rugged character of the topography, the absence of vegetation, and the abundance of prospect pits in this district, exposures are unusually good and many of the faults may be traced without interruption for considerable distances. Where associated flows contrast strongly in color, as the basalt or the dark-glass flows with the light-colored rhyolites, faults may be recognized a mile or more away. The faults on the south side of the mountain south of Sawtooth mountain are among the most conspicuous features of the near landscape around Rhyolite (Fig. 1).

Nearly 100 faults have been recognized in the area mapped. Some extend almost across the area, and others are short. There are two fairly well defined fault systems, one striking nearly north and south and the other striking N.30° to 50°E. (Fig. 2.) A number of faults, however, do not fall into either system. All of the faults for which sufficient data for classification are at hand are normal, that is, the hanging wall appears in every case to have been depressed. The vertical displacement of the faults, measured in a plane at right angles to the strike, varies from two or three feet to more than a mile. The accompanying figure (Fig. 3) shows by diagram the apparent vertical displacement of the faults. The sum of the apparent vertical displacements of all west-dipping faults which this section crosses is 12,500 ft., and the sum of the apparent vertical displacements of the east-dipping faults is 1250 ft. The difference is 11,250 ft., and from inspection of this figure it appears that this amount of depression toward the west has resulted from faulting.

Fig. 2. Plan of the Principal Faults in the Bullfrog District.

Striations or grooves on slickensided surfaces along fault-planes are made by hard particles or hard projecting points of rock rubbing against softer rock. They show that one or the other wall has moved in one of two opposite directions. Where there has been more than one movement along a fault-plane the striae formed by the first are likely to be erased by the last, and so those remaining, as a rule, record only the latest movement. Where hard particles formerly projected from one of the walls these are likely to have been worn symmetrically, and the most worn side in this case should be the side representing the direction from which the opposite wall moved with respect to the wall in which the worn particle is embedded. The amount of crushing and slickensiding along a fissure is not always proportional to the amount of displacement which has occurred between the separated ends of a formation. It is not uncommon to find smooth, well defined slickensides and one or both of the walls greatly crushed where the displacement has been very slight. On the other hand, great movement may take place along a plane no thicker than a knife blade and the rocks be not greatly shattered.

The attitude of the flows and tuffs in nearly every block of the fault mosaic is known through the presence of basal contact facies or of thin layers that

contrast sharply with layers above or below them. The position and dip of the fault-planes between the individual blocks are known from exceptionally good exposures on the surface and underground. In Fig. 3 rhyolite No. 7 has been projected under later strata of known position and above older ones, its position being determined from the thickness of associated beds near by or from the average section. Most of the dips of flows as platted were observed near the plane of the section, but where the rocks are concealed by wash their dip was assumed. Fig. 3 represents a length of eight miles. Rhyolite No. 7 is represented in each fault-block as extended to the next fault west, and if necessary is projected upward with the dip observed or assumed at the surface. In the fifteen fault-blocks in which rhyolite No. 1 appears in this section the total downward depression due to tilting (the sum of the vertical legs of the right triangles shown in Fig. 3) is about 13,000 ft., the projection of the flow (the sum of the horizontal legs of the triangles) is 30,000 ft., and the extent of rhyolite No. 7 in the plane of the section (approximately the sum of the hypotenuses of the triangles) is 33,600 ft. The figure shows a slope to the east, due to tilting, that averages about 39 ft. in 100 along the flows and corresponds to an average dip of about 23°E. in the plane of the section. This, however, does not represent the actual dip of the flows, but only their apparent dip in the section of Fig. 3. Since the strikes of the flows are not exactly at right angles to the plane of the section, the actual dip is greater than the apparent dip. Sixteen field measurements of dip near the plane of the section average 27°, which may be taken as a very close approximation to the average actual dip of the flows. The sum of the apparent horizontal displacements of all faults as shown on this section is 12,240 ft., which, added to the projection of rhyolite No. 7 on a horizontal line, equals the total length of the section, or 42,240 ft. (8 miles).

There are nineteen faults in all represented in Fig. 3 and of these all but two dip west. According to the interpretation made, rhyolite No. 7 is displaced by fourteen of the faults, of which two have a downthrow to the west. Measurements of these blocks, as shown in the figure, give for the sum of the apparent vertical displacements of the faults 13,750 ft.; for the sum of the apparent vertical displacements of the faults which depress rhyolite No. 7 to the west, 12,500 ft.; for the sum of the apparent vertical displacements of the two faults which depress rhyolite No. 7 to the east, 1250 ft. Thus the apparent net depression of rhyolite No. 7 toward the west, resulting from all faults, is 11,250 ft. Tilting depresses this same rhyolite 13,000 ft. to the east. The total apparent depression eastward, due to tilting and to downthrow to the east by faulting, is about 14,250 ft. Thus this flow as projected is only 1870 ft. lower at the east end of the section than at the west, and the tilting and faulting are nearly compensatory.

(*To be Continued.*)

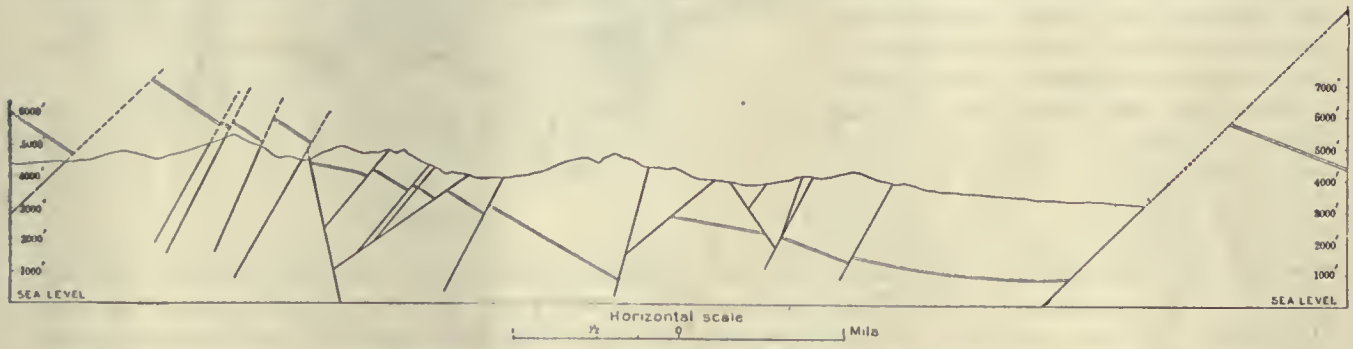


Fig. 3. Diagram Illustrating Displacement by Fault Lines at Bullfrog.

WESTERN AUSTRALIA GOLD INDUSTRY

According to figures published in 'The Gold Mines of Western Australia' the number of men engaged in gold mining in 1909 was 17,027; value of machinery, including 3900 head of stamps, £3,750,000; dividends paid in year, £1,359,115; dividends declared payable in January 1910, £112,719; total declared to January 31, 1910, £20,435,729. The following table shows the gold output, as reported to the Department of Mines for the year 1909, and also the totals for each goldfield since the records were begun in 1886:

Goldfield.	1909, fine oz.	1886-1909 inclusive, fine oz.
Kimberley	169	26,781
Pilbarra	5,529	229,008
West Pilbarra	1,396	22,007
Ashburton	228	5,569
Gascoyne	7	772
Peak Hill	7,322	204,561
East Murchison	148,238	1,058,202
Murchison	131,850	2,163,942
Yalgoo	627	54,577
Mt. Margaret	160,038	1,838,881
North Coolgardie	73,021	1,432,968
Broad Arrow	11,575	270,032
North-East Coolgardie	26,341	585,510
East Coolgardie	927,074	11,513,399
Coolgardie	36,663	1,275,869
Yilgarn	21,163	448,411
Dundas	35,895	411,831
Phillips River	7,631	41,625
Donnybrook	.....	840
State generally	502	22,183
Total	1,595,269	21,606,968
Value	£6.776.274	£91,780,565

The four best known and most promising copper-bearing regions of Alaska are the Kasaan peninsula of southeastern Alaska, the Prince William Sound district, the region included within the drainage area of Kotsina and Chitina rivers, and the region of upper Copper, Tanana, and White rivers.

The Long-Tom and Hydraulic Mining in California

By R. H. Campbell

On September 16, 1853, I arrived in Nevada City, California, with my parents, after a five-month trip across the plains with ox teams, a little alkalied but full of life and glad that I had come. Nevada City was at that time the greatest gold mining camp in the world, and while there were no real miners in the country, there were thousands of men engaged in gathering up the gold from the shallow creeks and river-bars, work that required little or no knowledge of mining. The pan, the rocker, and the long-tom constitute the only gold-saving devices used at that early date, the long-tom being used only in cases where the ground was from five to ten feet deep. Here the top soil, which contained too little gold to pay for washing in the long-tom, would be stripped by shoveling or by use of the wheelbarrow, and the rich bottom pay-gravel would be washed through the long-tom. Where the gravel bars were too deep to strip, the pay-gravel would be opened by drifts and wheeled out and washed in long-toms. That was nearly sixty years ago. I doubt if there are many living today that have ever seen a real long-tom such as was used in those days.

The long-tom such as was used by the early-day miner in California, was a shallow box about ten feet long and about twenty-six inches wide. The sides were about six inches high. At the lower or down-stream end, the sides were made to turn up like a sled runner, this portion being about three feet long. The bottom of this portion was of sheet-iron perforated with one-half inch holes. This sheet-iron portion of the long-tom was placed over what was called the riffle-box, a shallow box about five feet long with cross-riffles placed therein for saving the gold. The finer portion of the gravel, sand, and gold was discharged through holes in the sheet-iron into the riffle-box. The long-tom itself was set on a grade of perhaps twelve to fifteen inches, and the riffle-box set on a grade sufficient to carry the water and fine material that passed through the perforated sheet-iron. The water was generally conveyed to the upper end of the long-tom through a canvas hose.

Four men were required to operate the plant. Two men, one on each side, would shovel the gravel into the long-tom, the third would stand on a board laid across the riffle-box with a long-handled, square-pointed shovel, and as the material shoveled in was washed down to him, his business was to stir the mass until the fine material had passed through the holes with the water into the riffle-box. He would then shovel the coarser gravel out, while the fourth man stood in the tail-race below the riffle-box and shoveled away the sand.

This was before the days of sluicing. The stripping of the non-productive top dirt was the most expensive part of the work. The all important question among the miners was 'How much stripping do you have to do?' The Georgian said he had two 'ax handles' of dirt and one 'ax handle' of 'pay grit'. This might be considered an average depth and proportion. Soon the shallow ground became exhausted, and other and cheaper methods of handling the top waste materials than hand shoveling became necessary. Ground-sluicing during floods became the popular method of getting rid of the top dirt, or at least a good portion of it. To save moving the long-tom so often, handling the bottom pay-gravel, sluice-boxes began to be added at the upper end, and by putting riffles in the sluice-boxes, it was found that the gold could all be saved in these without the use of the long-tom. It was then that the long-tom disappeared as if by magic. Sluicing became the accepted method, and it was discovered that by leading the water about over the ground through canvas hose, even the little force the water had when discharging from the hose, could be made to help in washing the gravel. Then the idea of a pipe or nozzle on the end of the hose quickly followed, and hydraulic mining was born. From this simple practice the great hydraulic system was inaugurated, came into general use, and grew to enormous proportions. The evolution from the rocker and the long-tom to hydraulicking in its simplest form required about two years. It was not until some time in 1856 that iron pipe and giants were brought into use and began to displace the cotton hose and plain nozzle.

The Long-Tom.

I well remember while attending school in Nevada City in the winter of 1855-6 that Amos T. Lard, who at that time owned one of the deepest open-cut mines in the country, was operating a real hydraulic mine on Coyote hill, just outside the city limits. Previous to his turning it into a hydraulic mine he employed over one hundred men digging by hand. The seventy-five or eighty-foot bank was worked in benches. It was an interesting sight to see one hundred men working with picks and shovels breaking this high bank down into the sluice below; but a more interesting sight was to be seen in the spring of fifty-six when he brought the water in at perhaps an elevation of eighty or one hundred feet and had two lines of cotton hose about ten inches diameter, with nozzles at the lower end. Five or six men operated the entire plant and displaced the one hundred or more shovelers, at the same time producing far better results. So interested was I that the moment school was dismissed I would make a bee-line for the Lard hydraulic mine.

By this time the shallow creeks and river bars were becoming well worked out and were abandoned

to the Chinamen, while the attention of the mining men was turned to hydraulic mining in the deep ancient channels that exist so extensively in Nevada and adjacent counties. Quartz mining was little known, and aside from a few drift mines along the ancient channels, hydraulic mining absorbed almost the entire attention of the miners throughout the State. The power of water under pressure thrown against the bank through a hydraulic nozzle proved so effective that all the available water was soon appropriated and millions were expended in hydraulic mining enterprises. Immense dams, reservoirs, and hundreds of miles of ditches were constructed, requiring years to complete and at an enormous outlay of capital. Then it was that prosperity began to smile on California. The gold output, which, after the easy surface gold had been mainly gathered, had begun to diminish, began, with the introduction of the hydraulic system of mining, to rapidly increase.

The agricultural interests in the valleys below meanwhile had become extensive, and notwithstanding the enormous revenues that the farmers derived from the miners, they began war upon the hydraulic system of mining. At first the cry was little heeded, but it became stronger and stronger, and finally court proceedings were instituted against the hydraulic miners, who by this time had developed a most wonderful system of work. They were simply washing down the mountains and dumping the débris into the streams that flowed into the valleys, covering up the rich farm lands, forcing the abandonment of the latter. Not only were the farms destroyed, but the cities situated along the streams in the valleys were also threatened with destruction. The capital of the State, Sacramento, was in eminent danger of being destroyed. Hence the war against the hydraulic mining. Many of us well know of the bitter war which continued through every legislature of the State for over fifteen years. During all this time arrests and prosecutions of the miners for disobeying the court's injunctions were numerous. The miners in many cases would operate their mines, disregarding the court's injunctions. The farmers would send spies up into the mining districts to see that the miners were obeying the court's orders; the miners would often bribe the spies. In many cases lives were threatened, and one or two lives were lost in this bitter fight. It was not until the Federal Government stepped in and took a stand with the agriculturists in order to save the navigable streams of the State that the miners were forced to cease operations. The Government denied the State of California any further appropriations for her rivers and harbors until hydraulic mining ceased.

There is no law upon the statute books of California prohibiting hydraulic mining, but the Government has appointed a débris commission, and any one wishing to operate a hydraulic mine in the State of California must make application to that commission for a permit, and if upon examination, it is found possible to impound the débris and prevent it from entering the streams, a permit will be granted to operate under the hydraulic system. However, there are few places in the hydraulic district of California where large amount of débris can be impounded successfully, and this practically places a ban upon the system. It is unfortunate, for there still are in the western slope of the Sierra Nevada mountains, extensive deposits of gold-bearing gravel which would yield millions annually if it were possible to mine them with the hydraulic system.

Cost of surfacing roads with gravel by means of a traction engine outfit depends largely on the accessibility of the gravel. The greater part of the roads in the town of Glenville, New York, are surfaced with pit-gravel, the town doing the work. In the following cost data, covering a period of years, no account is made of the value of gravel. The outfit consists of a traction engine, four 5-cu. yd. cars, bin, and conveyors. It cost $3250. The average yearly repair bill has been $50, and the average cost of working per day without the bin has been $10. The average cost of working per day with the bin has been $16. When using the elevator and bins nearly double the yardage per day has been moved. The average cost per cubic yard of gravel placed on road (three-mile haul) has been 42c.; for a one-mile haul the cost has been 20c. per cubic yard, and in some cases the cost has been as low as 15c. The cost of surfacing one mile of road with 4 in. of gravel (three-mile haul) has been $350 to $400 per mile. The cost of surfacing one mile of road with 4 in. of gravel (one-mile haul) has been $225 to $300 per mile. The labor required is as follows:

	Per day.
One engineer	$3.00
One helper	1.75
Two laborers at $1.50	3.00
When using bin, one team	4.00

Low prices have resulted in closing a number of the Chilean nitrate factories, according to Rea Hanna, United States Consul at Iquique, who reports that the prices of nitrate March 17 was $1.59 per quintal (101.61 lb.) for the 95% product and $1.65 for the 96% product, with 1% salt, for immediate delivery free alongside ship. Of the 154 oficinas or nitrate manufactories in Chile, 55 were then not being worked, 36 being closed before July 1, 1909, on account of having worked out their nitrate grounds, or the cost of production from various causes having been too high. The oficinas in which the cost of production is low are reported as being worked to their limit, taking advantage of the cessation of restrictions regarding production, at the discontinuance of the nitrate combination. The opinions regarding the renewal of the combination are contradictory, and although strong efforts in its favor are being continually made by those whose cost of production is high, there does not appear to be any immediate prospect for a new combination.

A new type of steam-turbine electric locomotive, where a turbine of the impulse type is directly coupled to a direct-current variable-voltage dynamo has been completed and tested at the works of the North British Locomotive Co., Glasgow, Scotland. It is stated that these tests were very satisfactory and confirmed the theoretical claims made by its designers.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Skip Fillers.

The Editor:

Sir—I have been unable to find anything published on skip fillers for large shaft-bins, and as others may have been in a similar predicament, a discussion by those who have had experience should be of interest. Suppose that it be desired to hoist in a vertical shaft with a one-ton skip, loading with a skip filler that can be operated from the station. (1) Can it be made to work satisfactorily? (2) If so, what is the best arrangement? (3) Would chairs be necessary? (4) If it can be done, is it desirable, and what are the advantages and disadvantages as compared with the ordinary way of having a skip-tender at the chute while loading, and dispensing with a filler?

C. O. Moss.

Klau, California, June 3.

Wet Gold-Assay for Prospectors

The Editor:

Sir—In regard to Robert DeLuce's wet method for the assay of gold, I am sending results of some experiments made by me in testing the efficiency of the scheme. The individual operations proposed by Mr. DeLuce are all known to chemists, the solvency of gold in an iodine and potassium iodide solution, and its precipitation from the solution by shaking the latter with mercury being mentioned in Fresenius 'Qualitative Analysis.' It was to test the value of the method quantitatively, as well as the details of manipulation, that the following experiments were made. Ores of varying composition were selected. Several of these were very rich, it being manifestly easier to detect relative errors while working with a large amount of gold. The assay corresponds somewhat to the chlorination process for gold ores, the chief difference being in the method of precipitating the gold. The figures enclosed in parenthesis are the weights in milligrams of the gold actually obtained in the assay.

Experiment 1. Free-milling ore from Nevada; laboratory number of sample 5994. I ground one assay ton 10 minutes with the iodide solution and allowed it to stand over night; then filtered and washed a few times after the washings became colorless. The filtration was very slow. I shook with 3 gm. of mercury until colorless, and then a little longer; washed with distilled water by decantation in a porcelain dish, added 10 c.c. nitric acid and warmed. The gold, which was all in one button, was washed with distilled water by decantation, dried, and heated. The result was gold 1.30 oz., value $26.87. By fire assay, gold 1.30 oz., value $26.87; percentage extracted therefore was 100. The gold did not appear to be quite pure, and there was no doubt a counterbalancing of errors.

Experiment 2a. A slightly sulphide ore, laboratory sample No. 5890; a half assay ton was treated as in experiment 1. The filtration from the ore was quite rapid. In the reduction of the iodine solution with mercury the latter was broken up quite completely. Following the reduction of the iodine solution, a greenish mercury salt began to precipitate. Ordinarily in decanting from the mercury this precipitate, which settles slowly and goes over with the washings, carries with it gold in weighable quantities only with very rich ores. The mercury after treatment with nitric acid left the gold in a finely divided condition. Result, gold (18.64) 37.28 oz.; value $770.58; fire assay, gold 78.81 oz.; value $1629; percentage extracted 47.73. The gold at first was not pure, basic mercury nitrate, yellowish in color, separating out on diluting and washing with water. This dissolved on re-treating the gold with dilute nitric acid.

Experiment 2b. The residual ore from experiment 2a was re-treated with iodine and a small amount of gold, approximately $10 per ton, was recovered.

Experiment 2c. The reduced iodine of 2a was shaken occasionally for one day with mercury, and a minute amount of gold, less than $1 per ton was obtained. Subsequent experiments showed that ordinarily the loss due to incomplete precipitation of the gold from the iodine solution is practically nil.

Experiment 3a. Roasted 1/20 assay ton of No. 5890 at a low heat in a porcelain dish until no smell of sulphur could be observed; shook with iodine solution in a bottle occasionally for two days, and reduced with mercury as before, shaking from time to time throughout one day. The greenish precipitate noticed in 2a occurred as before, and indeed was quite general in all subsequent experiments, varying in color with the ore used. I washed the separated gold with dilute nitric acid to avoid precipitation of basic salts of mercury. Result, gold (2.81) 56.20 oz.; value $1161.65.

Experiment 3b. The residue from 3a was re-treated with iodine solution, shaking once in a while for two days, filtering and precipitating the gold as before. There was recovered gold (0.50) 10.00 oz.; value $206.70.

Experiment 3c. The reduced iodine solution from 3a was again shaken with mercury, but no gold was recovered. The total gold obtained from these experiments was 66.20 oz.; value $1368.35; percentage extracted 84.

Experiment 4. Sulphide (pyritic) ore; concentrate from Alaska: laboratory sample No. 6111. Treated as in the original method, grinding 1 assay ton for 10 minutes in a mortar with the iodine solution, etc., I obtained gold 1.84 oz.; value $38.03; fire-assay gave gold 3.23 oz.; value $66.76; percentage extracted, 56.9.

Experiment 5a. No. 6111. Roasted 1/5 assay-ton in a porcelain dish as in experiment 3a; shook with iodine solution occasionally for two days, and then with mercury for two days. The gold which weighed 0.46 mg. was evidently mixed with small particles of glass rubbed from the inside of the bottle during the shaking with mercury. On amalgamating the gold with a very small amount of mercury, the amalgam

was easily separated from the glass, and the gold extracted by treating with nitric acid as usual. Obtained gold (0.40) 2 oz.; value $41.34. This mixture of glass with the gold was frequently observed, and unless the gold was in one or two pieces amalgamation with mercury had to be resorted to.

Experiment 5b. The green precipitate resulting from shaking the iodine solution with mercury was treated for gold, but none was found.

Experiment 5c. The residue from 5a was extracted with iodine for two days and the dissolved gold separated as usual. Obtained gold (0.22) 1.10 oz.; value $22.74; total extraction from 5a, 5b, and 5c, gold 3.10 oz.; percentage extracted, 96.

Experiment 6. No. 6111. Treated ½ assay-ton with dilute nitric acid; filtered, burned the filter-paper, and shook the ash and residue for two days with iodine solution, and finished as usual, amalgamating the gold to free it from glass. Obtained gold (1.62) 3.24 oz.; value $66.97; percentage extracted, 100.3.

Experiment 7a. Rich telluride ore from Nevada, containing 2.08% copper, 2.42% tellurium, and 0.35% bismuth; laboratory sample No. 1520. Treated 1/20 assay-ton with nitric acid, boiled to within a few cubic centimetres of dryness, added hydrochloric acid and boiled to dryness. Shook the residue for two days with iodine solution and extracted the gold as usual. Obtained gold (25.50) 510 oz.; value $10,541.70; fire-assay, gold 584.62 oz.,; value $12,084.10.

Experiment 7b. Decanted again the washings from the mercury extraction of 7a in an endeavor to recover any gold carried over. Gold (0.04) 0.80 oz.; value $16.54. Evidently more gold escaped, but its relative value to the total amount of gold was small.

Experiment 7c. The residue from 7a was re-treated with iodine solution and an extraction obtained of gold (0.34) 6.80 oz.; value $140.56.

Experiment 7d. Reduced iodine solution from 7a, was re-shaken with mercury and gold obtained (0.27) 5.40 oz.; value $111.62. Total extraction in experiment 7; gold 523 oz.; value $10,810.41; percentage extracted 89.4.

From the few experiments made above, while not broad enough to be conclusive, it will be seen that the method has some merit. It probably is as good as, if not better than, any of the other wet methods devised for the assay of gold. Except with ores of extreme richness the precipitation of the iodine solution with mercury, the washing of the precipitate by decantation, the separation of the gold by washing the amalgam with nitric acid, followed by washing with dilute nitric acid, is practically quantitative. Where mixed with glass, a second amalgamation with mercury will allow the gold to be easily separated from the glass.

It is with the chemical and physical condition of the gold in the ore that the chief difficulty of the method lies. Where the gold was unalloyed, untarnished, and unconfined, as in experiment 1, its solution in iodine was quite rapid. With raw sulphide ores and concentrate the solution was incomplete. Where the latter were roasted an increased extraction resulted. No experiments were made with a dead roast. The treatment of the sulphide ore in experiment 6 with nitric acid, the only experiment made along this line, resulted in quantitative work. The single telluride ore experimented with gave incomplete extraction. In this experiment the residue boiled to dryness was probably heated to above 180°C., at which temperature the auric chloride ($AuCl_3$), soluble in water, would be changed to aurous chloride (AuCl), insoluble in water, and might have some effect on the result. It is hardly fair to test the method with such an unusual ore as this, where the gold in addition to being combined with tellurium, may also be alloyed in small amounts with other rare metals. Furthemore the relative errors seem to increase more rapidly with the wet assay than with the dry, as the richness of the ore increases. As regards the chemistry of the process the gold probably goes into solution with the iodine as auric iodide (AuI_3). From this the mercury precipitates it in the metallic state and then combines with the iodine to form greenish mercurous iodide, Hg_2I_2. This is blackened by light and should not be mistaken for the gold precipitate, which is much heavier. This mercurous iodide is partly soluble in the potassium iodide, and is easily removed by treatment with nitric acid, being soluble also in mercury nitrate. Dilution of the mercury nitrate solution, produced by the action of nitric acid on the mercury in freeing the gold, results in the formation of basic mercurous nitrate $xHg_2O.yN_2O_5.zH_2O$, a yellowish white precipitate insoluble in water but easily soluble in dilute nitric acid.

For practical purposes, I would suggest that all ores of unknown composition be first treated with nitric acid, or, where tellurides are suspected, with aqua regia. The residue should then be shaken in a glass bottle for as long a period as may be convenient, and filtered. Where filtration is slow, making up to a definite volume, and filtering through a dry filter, and taking an aliquot portion of the filtrate for shaking with mercury, will be in order. The bottles should have well fitted stoppers. With ordinary precautions to obtain the gold in a pure condition it can be worked up into a button where the limit of error should be within the error of estimating the amount of the gold with other buttons of known weight. By using aqua regia, as suggested, the chances of overlooking gold tellurides are slight.

James W. Howson.

San Francisco, June 4.

The China Copper Co., according to its report for May, has a tonnage of developed and partly developed ore aggregating 18,798,078 tons, of an average grade of 2.59%. This is an increase for the month of May of 849,512 tons, the grade being the same. The amount of ore per acre now averages 323,000 tons. The total aggregate ore is now given as 8,725,000 tons fully developed ore and 10,073,000 partly developed ore. The company is now planning to carry on drilling to a greater depth. The above amounts of ore have been developed by 208 holes, covering an area of 58 acres. The average thickness of the capping is 82 ft., and the average thickness of the ore 96 feet.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Potassium cyanide is manufactured at Kolin, near Prague, Bohemia, from a mixture of lye and a thick molasses which is itself a by-product from the manufacture of beet sugar.

Wire screens are subject to irregular wear, due largely to uneven feed distribution and to rust. In a general way, however, their life is proportional to the square of the thickness of the wire.

Churn-drill exploration on a mining claim, performed for the discovery or estimation of quantity and character of ore deposits, or for the benefit of a deposit held under a valid location, is accepted as annual assessment work.

The rating of air-compressors, when expressed in the number of rock-drills to which they are capable of supplying air, is usually based upon a consumption of a volume of air at 60 lb. per square inch pressure, equivalent to about 100 to 110 cu. ft. of free air per second.

The Central Eastern line of the Japanese railways has been burning crude oil on its locomotives since April 1. This line was chosen by the railway board on account of the many tunnels, passing through which the passengers have heretofore been greatly annoyed by the accumulations of coal smoke.

Kimberlite, the rock in which the South African diamonds occur, is found in Arkansas and eastern Kentucky. Nearly identical rocks occur in western Kentucky, southern Illinois, at Syracuse, New York, and in the highlands of the Hudson. Diamonds have only been found in the Arkansas occurrence.

Siphons should always be built with a valve at the outlet so that the pipe may be completely filled with water. At the crown of the arch another valve is necessary to permit the escape of air, or the introduction of water. Any convenient size is used. This may need to be opened for a few moments several times a day. Automatic relief valves are not recommended for such a situation.

Bench deposits at different levels from a foot to several hundred feet above the present streams are common in many of the larger drainage areas in the Yukon-Tanana region. In the Fortymile district they occur on the high benches of Fortymile creek and some of its tributaries to a level of at least 300 ft. above that of the present streams. In the Rampart region there are bench gravels 500 ft. above the valleys.

In the square-set system of timbering, the framing must be suited to the direction of pressure of the superincumbent mass as demonstrated by experience in each mine. Where there is a heavy downward pressure, such as is often observed where the ore-body stands nearly vertical, the timbers are so framed that the posts meet when placed in the set. In veins inclined flatter than 65°, where the heavy pressure is evidently on the hanging wall side, the caps may be so framed that their adjacent ends butt one on the other. Angle braces are often used to resist a diagonal thrust, but filling is far more successful when possible, and allows the use of much lighter timbers.

The Mancayan copper mines are near the town of Mancayan in the northern portion of the island of Luzon in the Philippines. The veins are wide and the outcrops have been traced for over seven miles. The Igorots, who are natives of this district, have mined both gold and copper from this belt as far back as the history of the tribe can be traced, and have supplied the other inhabitants of the island with copper spears, pots, and pipes. According to record, they exported 20 tons of copper per year from 1840 to 1855.

Fine revolving screens operating on wet pulp act differently from dry shaking screens such as are used in a laboratory. The time allowed for screening is shorter and the particles of ore are not given the same number of chances to pass through. Fine wet machine screening is very rapid and therefore sand grains just large enough to pass through the meshes will often bridge over the openings and not go through. The result is that the undersize will always be of greater fineness than the corresponding product obtained by dry screening in the laboratory.

Mica occurs in dikes of coarse granite. These dikes are mined in the same manner as veins, the rock being sorted either underground or on the surface, or both. The mica is found in groups of crystals called 'books', owing to the cleavage of the mica plates, which resembles the leaves of a book. These books are split up, the good mica sorted out and cut by machines into as large sizes as the shape of the leaves will admit. The sheets are bound together in packages and shipped to stove manufacturers and others. The waste is used largely for electric insulation, as a base of lubricating compounds, and in the manufacture of wall-paper.

Artesian wells are now used to water about 2,194,674 acres of grazing land in Australia, and the watering of a further area of 380,960 acres has been undertaken. In addition a number of private wells have been sunk so that approximately 3,000,000 acres will be permanently watered. Many of the rivers of New South Wales, according to the last annual report of the Department of Public Works of that State, are simply drainage channels running through flat country, flowing after heavy rains and dwindling to a chain of water holes during periods of severe drought. Cattle men in some instances excavated tanks to catch a rain-water supply for their stock, but this method of storage was not always successful. Dams also were built across some of the creeks, but owing to the friability of the soil the surplus water soon cut out other channels, and additional dams had to be made. The ground-water supply, according to the report, lies in some places 3000 to 4000 ft. below the surface.

Special Correspondence

LONDON

Mount Lyell Reports.—Chester Soon to Ship.—Zeehan-Montana Buys at North Dundas.—Great Fingall Consolidated.

Results of the work at Mount Lyell for the half-year ended March 31 have been received in London by cable. The feature of the period has been the commencement of the treatment of the large body of low-grade ore. The total amount of ore treated during the half-year was 190,396 tons, of which 122,816 tons came from the Mount Lyell mine and 67,580 from the North Mount Lyell. The average content was 2.61% copper, 1.89 oz. silver, and 0.78 dwt. gold per ton. The blister copper produced was 4164 tons, containing 4114 tons copper, 338,976 oz. silver, and 7627 oz. gold. The production of blister copper was 374 tons less than in the previous half-year, owing to the lower content of the ore treated. In addition to the ore smelted, 6143 tons of sulphide ore was used for the manufacture of acid. At the beginning of the half-year 1295 tons of copper was unsold; this has since been sold at an average price of £59 1s. Of the copper produced during the half-year 2755 tons was sold at an average price of £61 11s. per ton and the remaining 1359 tons carried forward. The profit for the half-year was £115,335, after allowing £6094 for taxes, £10,076 for depreciation, and £13,954 for exploratory work. The dividend distributed absorbs £105,000, being at the rate of 1s. 9d. per £1 share. The cost of producing the blister copper was 16s. 4d. per ton of ore, 11d. higher than during the previous half-year, owing to low-grade ore being taken from Mount Lyell, and partly to more coke being used in the charge. The coal strike also accounts for some parts of the rise in costs. The reserve of ore is given as follows: At Mount Lyell, available by open-cut, 539,042 tons averaging 0.6% copper, 1.93 oz. silver, and 0.86 dwt. gold per ton; available by underground mining, 2,433,977 tons averaging 0.52 copper, 1.97 oz. silver, and 0.5 dwt. gold per ton; at the North Lyell, 842,163 tons averaging 6% copper, 1.33 oz. silver, and 0.1 dwt. gold per ton. This is an increase in the reserve at North Lyell during the year of 75,000 tons, and it is the highest figure yet recorded. An important new orebody has been discovered on the 850-ft. level of the North Lyell, and developments on the 1000-ft. level have been excellent. On the 1100-ft. level the orebodies are of as good quality as any found hitherto, a fact which gives great hope for the future. As already mentioned, underground reserves at Mount Lyell are now being drawn on. As regards outside interests, the Chester mines will soon be producing regularly and small shipments have already been made to the acid works. Prospecting has been continued with encouraging results at the Frankland River properties on Norfolk range, and has been started at the Hazelton group. The coal strike interfered with the coke-ovens at Port Kembla, and operations were suspended for several months, but the smelter was not inconvenienced because a large reserve of coke was in hand. The production of fertilizers has been well maintained at Yarraville and Port Adelaide, though at the latter operations were impeded to a small extent by the strike. The new fertilizer works at Fremantle will be ready to commence production shortly.

The Zeehan-Montana silver-lead mine was floated in London in 1892 as a subsidiary of the Mount Zeehan (Tasmania) Silver-Lead Mines, which still holds a large share interest. The property is situated on the west side of Tasmania not far from the coast. The mine did well until two years ago, when the developments became disappointing. At the end of 1908, the reserve of ore was practically exhausted and the outlook was dark. The manager, John Craze, persevered, and has had his opinions backed during the year by the Government geologists who made a special examination of the Zeehan district with a view of determining the chance of further discoveries. The report of the company for 1909 shows that Mr. Craze has been rewarded by the discovery of several small bodies of ore, and of one body which promises to develop into a valuable reserve. During the year 3435 tons of first-class and 16,618 of concentrating ore has been raised. The shipments consisted of 2090 tons of ore and concentrate sent to Antwerp, assaying 67% lead and 84 oz. silver, and 1247 tons sold to the Tasmanian Smelting Co. averaging 60% lead and 51 oz. silver. The concentrating plant treated 9950 tons coming from No. 1 shaft assaying 9.4% lead and 11.4 oz. silver, and yielding 1079 tons of concentrate averaging 67% lead and 75 oz. silver, and 6515 tons coming from No. 2 shaft assaying 12.4% lead and 11.4 oz. silver, yielding 786 tons of concentrate averaging 65.8% lead and 55 oz. silver. The plant also treated a few hundred tons from No. 4 shaft and a small amount of tributers' ore. The concentration was efficient, as only 1% lead and 2½ oz. silver were left in the tailing. The cost of crushing and concentration was just under 3s. per ton. Though the prospects at the mine have improved during the year, the directors have considered it the safest policy to try other properties, and Mr. Craze has therefore investigated the new tin district of North Dundas, a few miles away. A property has been bought for the small sum of £1250; it contains three different outcrops, each about 40 ft. wide, and giving results 1% and upward. The development of this property will be watched with unusual interest. The company has also taken a small interest in a new silver-lead property at Dundas acquired by the Mount Zeehan company. As regards the financial position of the Zeehan-Montana, the report shows that the sale of produce brought an income of £40,081 and the expenses at the mine were £40,721, the London expenses £667, and depreciation £840. There are other items in the account, and the net result of the year's work is a loss of £1725.

The Great Fingall Consolidated, a gold mine situated at Day Dawn, Western Australia, and managed by Bewick,

Moreing & Co., is now approaching exhaustion. Milling commenced in 1900 with 20 stamps, and since then the plant has gradually been extended until it now consists of 100 stamps, concentrators, roasting furnaces, and cyanide plant. Unfortunately during the last two years the developments have been unsatisfactory, and toward the end of 1908 the average content of the ore sent to the mill was considerably reduced. No further bodies of ore have been discovered, and only 40 of the 100 stamps were at work during 1909. The policy of the managers is to attack the rich pillars left in the mine. This cannot be done without first filling the stopes with sand, and the latter work is now in hand. The company owns approximately a quarter of a million tons of accumulated slime that has been hitherto considered unprofitable. This is now to be treated by the new vacuum slime plant recently erected. During 1909, the 40 stamps in operation crushed 140,982 tons yielding by amalgamation 21,074 oz., 1877 tons of concentrate produced 6039 oz., 105,225 tons of sand 8042 oz., 19,339 tons of current slime 1333 oz., and 77,280 tons of accumulated slime 4781 oz., a total production of 41,269 oz. The income from the sale of gold was £175,716, and £2900 was received as interest. The cost of treatment was £156,300, the London expenses £3150, depreciation £9181, and taxes £9240, leaving a margin for the year of only £320. In addition £25,888 was spent on capital account for development and additional plant. The company commenced the year with a balance in hand of £24,339, out of which £21,875 has been distributed as dividend, being at the rate of 8¾%. Irrespective of the rich pillars, the available ore reserve on December 31 was 49,460 tons averaging 23s. 9d. per ton. Owing to the insecurity of the workings it is impossible to enter for the purpose of measuring the other ore or the pillars until the sand-filling is in place. The company has a reserve of £95,000 in cash, and steps are being taken to employ it in developing other mines. A property has been acquired in West Africa and has been floated as the Taquah Central Mines, Ltd. Of the capital £40,000 has been subscribed by the Great Fingall.

JOPLIN, MISSOURI

Zincite Developing.—Disseminated Region Opening Good Ore.—Duenweg Mines Active.—McGee Silicate Mine.

Greater activity is noticed in the old Zincite camp near Joplin than at any time for a number of years. On a lease of the Llewellyn tract a party of Joplin men has just drained the mine to a depth of 133 ft., and a rich face of ore is now in shape for working. Some of the ore is free, while some requires milling, and it has not been yet decided whether to build a plant on the lease or haul the ore to a custom mill. Hand-jigs are being used temporarily. The Victoria M. Co., operating in Cottonwood Hollow, a portion of Zincite, has recently entered one of the largest bodies of ore found for some time. The present shaft is down 112 ft., although the ground is worked at 88 ft. The ground is soft and requires timbering. Both high-grade galena and zinc blende are taken out, much of the galena being ready for market without further treatment. The mill dirt is treated on the 150-ton plant of the Clara Bell, near by. The Clara Bell itself is carrying on additional development, driving two drifts at 126 ft. A better grade of ore is being found than any hitherto reached. An old shaft is down 140 ft. and it is said that good ore exists in the bottom of this shaft. It will be reached by a drift. The dirt will run 9 to 10%, being mainly blende. Operations are also being resumed on the Wyssbrod land at Zincite, upon which is situated the old Daylight and Colgen mines. Eight shafts are in ore on this 75-acre tract, and two custom mills operate. The work will now be begun upon an extensive scale, and the Daylight mine will be re-opened. It was formerly one of the best producers in this camp. The ore-face is 24 ft. high in the open pit and the ore is mainly zinc blende.

Just west of Joplin the Kittie Mack company is building a new mill to replace the one burned. The lease is well developed, and when completed the mill will be a steady producer. It is situated in the disseminated-ore region opened up only a few years ago, but now containing some important mines. The mill will handle about 250 tons of ore, and is constructed of galvanized iron and is new throughout. The Hercules, another mill in the same region, is just completed and has the largest capacity of any plant in that field. It is rated as a 500-ton mill, equipped throughout with Foust jigs and every modern improvement. It has made the initial 'turn-in' and will be ready for steady operation, as the ground is well developed. Matthes Bros., owning a large acreage near Jackson Station, have just purchased the Claram mill south of Webb City and will remove it to their land at once. A long campaign of prospecting has shown a rich run of shallow ore and shafts have been sunk and the ground well opened in a promising deposit. The ore is free in character and runs from 5 to 8% zinc. The strike is not far from the H. H. Gregg land, where a number of shallow-lying orebodies have been found.

The Jack Hayward company southwest of Joplin is preparing to take up a 15-ft. stope, extending from the 175-ft. level. The work is to be done by placing a steam-hoist in the drift to operate a car on an inclined winze. This will save the work of sinking a new shaft or opening a large stope outward from the shaft. The company has put down several drill-holes on the eight lots and has discovered ore at a lower level in sheet-ground. The ore where the winze is being worked appears to be in the form of a chimney extending down to this sheet-ground level. There is a 150-ton mill on the lease. The old Pilot mine southwest of Joplin is being re-opened and the company re-organized. Recent prospecting in this vicinity has opened many shallow and deep deposits and a number of new shafts are being sunk. The shaft at the Pilot will be deepened to the 195-ft. level. Former operations were conducted at much shallower levels. A large mill is already on the property. To the north of this property George Noble and others are beginning the sinking of a shaft on a lease of Matthes Bros.' land, where several encouraging prospects have been found. A 24-ft. face of ore was drilled through in three holes. Aside from drilling, this property has never been developed. There is no abatement in the interest in the vicinity of Toms Station, where during the entire spring months and late winter steady prospecting has been going on. Many discoveries have been reported, and J. M. Short has been actively drilling. A rich discovery has been reported, widening the mineralized territory. The ore in the last hole was found from 153 to 186 ft. This makes the fifth hole down, all hitting the orebody. A few more holes will be sunk and then shafts will be started. A well defined and rich orebody of considerable extent has been blocked out. Some of the cuttings assay as high as 27%. Others assayed from 15 to 20%, and others below this grade. The many discoveries made by Mr. Short, Wells Bros., and others have stimulated much interest in prospecting in the vicinity and there is a great demand for leases. A short distance away on the Mexico-Joplin land, S. L. Bradley has taken a lease on 40 acres, where five drill-holes have been sunk. More drilling will be done by the new owners before further development is undertaken. The ore has been found from 120 to 150 ft. in depth, while in other holes the run did not appear above 160 ft. On an adjoining tract good ore was struck at 40 ft.

The Holy Moses mine at Four Corners made its initial turn-in recently, consisting of 70,000 lb. of blende cleaned on hand-jigs. A second shaft is being sunk to increase the output of the mine. A mill will be built if the dirt proves suitable. The ore is found at 70 ft., at which depth three drifts have been well opened, showing a 12-ft. face. The McGee silicate mine in the Duenweg camp, already famous as a long-lived producer and a rich property, has recently been extended by the opening of another rich run. A record run of the mine was made recently when in six shifts 126,000 lb. of ore was turned out, making over ten tons per single shift. Considerable difficulty has been met recently in keeping the boilers running steadily owing to the scarcity of coal. A silicate mine in this field is usually short lived, but this property has produced steadily for over two years, and while still the best silicate producer in the district has a large amount of ore in sight. The initial turn-in has been made from the new mill on the old White Rat lease at Duenweg. The mill is the former Myrick-

The newly developed ore in the White Rat is in sheet-ground, lying partly beneath the drifts on the former lease. Another producer has just been started up in the Porto Rico camp by the New York & Western Co. on a lease of the Knol land. The lease was formerly worked and was a steady producer of high-grade ores. A mill has been started by Henson and McDonald on the Troupe ground, where operations many years ago showed ore which was considered too thin to be operated at a profit. A later run was taken out averaging 10%, and a large tonnage of high-grade ore was produced. The plant has been recently erected and the land will become a steady producer. An important discovery has been made in the Neck City camp by Gardner and associates, where at a depth of 74 ft. the shaft passed through 9 ft. of almost pure galena with a small percentage of blende. This is the richest ore in this portion of the camp, though it is in the centre of the Neck City mining field. The company will erect a plant as soon as the shaft is completed.

MEXICO

Altar Placers.—Auto Stage.—Quenner Machines.—San Antonio Placers in Banauca District.—Boleo Copper.

It is believed there will be great activity in the dry placer regions of the Altar district of Sonora in the fall. A great area of placer has been denounced during the last several months, and titles to properties are now being awaited, the new mining law of Mexico providing against the working of claims until titles are secured. The towns of Nogales, Sonora, and Nogales, Arizona, recently arranged funds for an automobile road from Nogales to Altar, the centre of the district, a distance of 90 miles, and it is planned to have this road completed by July 15. H. J. and W. E. Karns, of the Sonora Auto Co., will establish a regular service on the new road, a car going to Altar one day and returning the next. The trip each way will be made in six hours. It is also proposed to operate a car between Altar and Boludo, where some placer work is now in progress, a distance of 36 miles, and later this service will be extended 20 miles to La Cienega, around which point there are many placer denouncements. After the close of the rainy season in the fall the automobile service may be extended from Altar through Caborca to Port Lobos, on the Gulf of California. Ten of the Quenner crushing machines, which are principally responsible for the present interest in the dry placers of the Altar district, are being built at the shops of Roy & Titcomb, in Nogales, for the American Ore Milling Co., the concern that was recently organized to take over a 70% interest in the Quenner patent and build and install the machines. D. A. Richardson, of Douglas, Arizona, is at the head of the enterprise in the southwest. This company is successfully operating a Quenner machine at a placer near Boludo. Jose Monteverde, who bought the placer lease and machine of Mitts Quenner, the inventor, and Charles H. Peck and J. E. Suits & Co., are also operating Quenner plants in the Boludo section. Lawton B. Garside is installing a Quenner machine at placers nine miles east of Llano, a station on the Sonora railway, and George D. Stonestreet, representing New York interests, is operating five miles west of that point.

Exploration work with Keystone drills is in progress at the old San Antonio placers in the Banauca district of Sonora. These placers are now held by New York men represented by Herman Wendler, a well-known mining engineer. The exploration work will be continued for three months, and if at the end of that time the results are as satisfactory as they have been up to this time, expensive dredging equipment will be installed. During colonial days several millions were taken out of the San Antonio placers. The gold is found along a former channel of the Yaqui river and in gulches leading into it from the mountains. The Spaniards worked down the gulches from the mountains until the underground flow of the river stopped them, getting gold in the lower sections of the gulches only above the water level. The town of San Antonio, founded early in the eighteenth century, is on gold-bearing ground, and the plans of the New Yorkers call for the building of a new town outside the placer-zone and the destruction of the old one. Mr. Wendler has made arrangements with the inhabitants—about 60 families, for the change. A close corporation is being organized to carry on the placer operations. In the mountains above the San Antonio placers the Yaqui Mines Co., an English concern, is working a gold property with good results. A 12-ft. ledge of $13 free-milling gold ore has been cut. This company is closely identified with the Hudson's Consolidated, which has extensive interests in that section of Sonora. Mr. Wendler is also in charge of the operations of the English concern.

It is authoratively stated that the profits of the Boleo Copper Co., the French concern operating in Lower California, have averaged more than a million francs a year since 1900. The company has a capital of 12,000,000 francs, divided into 120,000 shares of 100 francs each per value. Just at present the Boleo has several important plans, among them the installation of converters and the shipment of their product as blister copper instead of matte. Matte of about 63% is now being shipped. French steamers taking it to Dunkirk and Liverpool, via the Straits of Magellan. A shipment of pyrite is to be brought from Spain for experiments in ore combinations as at present the percentage of copper lost in the slag is high, and a better extraction is demanded. It is stated that if good results are obtained by the experiments the operation of the Inguaran mines in Michoacan, controlled by the same interests and where supplies of pyrite are available, may result. Extensive development has been done at the Inguaran properties, but the construction of a railroad to the Pacific Coast would be necessary to permit of the shipment of Inguaran ores to Santa Rosalia, the port of the Boleo Copper Co., where the Boleo smelter is located. The Boleo production is now averaging a little more than 1000 tons of copper monthly. The concern is controlled by the Paris branch of the Rothschilds.

GOLDFIELD, NEVADA

Mine Inspection.—Consolidated Improves Conditions.

The Goldfield Consolidated Mines Co. has recently organized a division of inspection and is making especial effort to increase the safety of its men and property. Within a few weeks the surface drainage and sewage systems have been improved, and with the work planned will provide for the disposal of all waste water and refuse in a sanitary manner. Antiseptics are used in all drains, pits, and places where gases are liable to arise. As fast as possible, the general appearance of the surface is being improved. Old buildings are being removed, scrap material is being hauled to an out of the way place, and provisions made to prevent such material from accumulating around the property. A high-pressure water system for fire-fighting purposes, has been planned and is now under construction. A reservoir, located on top of Columbia mountain has been started and pipe-line trenches through solid rock are now about completed down to the foot of the mountain. Material has been ordered to install this system, including pipe, high-pressure pumps, hydrants, hose, and a full equipment to insure complete protection against fire. The properties are divided into fire divisions, each of which will have a fire house, with its own equipment. Each division will have its own captain and fire organization which will be thoroughly drilled and ready at all times to respond to an alarm. Each of these divisions has been supplied with a 40-gallon Badger chemical engine. These, together with the hand extinguishers, will afford ample protection against small fires. Fire helmets for use underground in case of fire, have been ordered and upon arrival of these helmets men will be trained to use them so as to be able to protect both life and property underground. A regular inspection of hoists, cages, shafts, and ropes is now practiced. This, together with the co-operation of efficient engineers and cage tenders, will insure good protection to men from accident, while being lowered or hoisted from mines. A close watch is being kept on all ladderways and main passage ways, in all parts of the mine to insure perfect safety. All surface plants and machinery are being inspected and where

ever improvements can be made to guard against accidents they are being made. One line of work in particular that the inspection department intends to take up will be to investigate the causes of disease peculiar to underground workers, and, if possible, to take steps to eliminate the cause, if such is found in the mines of the Consolidated.

NEW YORK

Copper and the Merger.—British Columbia.—Mines Company of America Reorganized.—La Dura Purchased.

A strong tone of optimism is developing in the market and the expectation is general for increased activity at higher prices. The liquidation engendered by the action of the Federal Department of Justice in bringing the injunction suit against the Western railroads seems to have run its course. The natural optimism of the country is beginning to assert itself. The one weak spot in the market is the copper situation. The companies controlling the low-grade milling properties have command of the market, but in the case of Utah Copper practically all of the net proceeds from operation is being paid out in dividends. This company is producing on a basis of about 100,000,000 lb. per annum, and is paying $3 per annum in dividends, while earning about $3.13 per share on the present copper market. This leaves the dividends derived from Utah's half interest in Nevada, amounting to $1,425,000 in round numbers, to be carried to surplus account, but this is as broad as it is long, since Utah's interest in Nevada Con. was acquired by the exchange of stock. In a recent interview L. Vogelstein, of L. Vogelstein & Co., said in part: "It is production rather than the consumption which unsettles the market, especially as, taking a long distance view of the situation, the outlook is for more copper in 1910 than in 1909, and more in 1911 than in 1910. The total production for five months of 1910 was 590,047,362 lb., compared with 564,825,116 in 1909. Great hopes having been entertained that good business during the second half of the year would enable demand to keep pace with supply, discouragement is proportionately keen at the prospect that these expectations may be disappointed. If the market has been leaning on a broken reed in this respect there would seem to be nothing now, in the absence of a copper combination, except for the inexorable law of supply and demand to take its course until an equilibrium between supply and demand is established." There is a serious revival of talk of a copper merger. The combination is evidently to come. The real question involved is what coterie of financial interest is to dominate it. The Lake coppers with their Boston connections have always held aloof from the Western mining interests. Among the latter the three groups of leaders are evidently sparring for an opening. The Phelps-Dodge interests are believed to be preparing to land copper in New York by trans-shipment across the isthmus of Tehuantepec. The Cole-Ryan party is working with the Anaconda and making a strong bid for leadership, while the Guggenheims are at the moment in command of the low-grade porphyries. Any three-cornered battle between these groups would be so expensive that it may be safely said that the banking interests involved would interfere. Amalgamated's position is becoming more and more questionable. Its market level is so far out of proportion to its income that the shares must come down in price. The heaviest financial powers of the world are identified with copper, and they have learned the advantage of unification over competition. The copper merger is probably more nearly at hand now than it has ever been at any time heretofore. A daily copper production of 4,000,000 lb. makes some effective market protection necessary.

Operations at the British Columbia are about normal once more. Ores from the Wellington mines are being received. Shipments from the New Dominion begin this week. Two furnaces are in blast, while the third is being enlarged. When alterations are completed, which will be in the course of 60 days, the plant will have a daily capacity of 2700 tons. The action of the Granby directors in withholding the report of Vice-president Jay P. Graves is taken to mean unequivocally that the conditions exist as outlined in the Sussman report. The rejuvenation of the Granby is indefinitely postponed. The Butte and Ballaklava, at Butte, Montana, is proving to be a twin discovery for Tuolumne. Both properties are of comparatively small acreage and both are phenomenally rich. The Butte and Ballaklava has made some copper, which it is claimed was all profit, the precious metals paying all expenses. Tuolumne's million pounds of copper per month has been made from ore running from 10½ to 15% copper, and copper costs have been probably below 6c. The concentrate from the Miami mill, now in course of construction, are to go to Douglas, to the Copper Queen smelter. The management negotiated with the Old Dominion smelter at Globe, but in order to handle the concentrate additional reverberatory furnaces would have had to be provided at a cost of a quarter of a million or more, so that the Old Dominion company preferred not to undertake the contract.

It is some ten years or so since the Colorado Creston properties at Minas Prietas, Sonora, Mexico, were taken over as the Mines Company of America by a group of Western capitalists familiarly known as the 'Gates crowd'. Among the prominent figures were John J. Mitchell, president of the Illinois Trust & Savings Bank, of Chicago, who is supposed to be J. P. Morgan's right hand man in all of the latter's affairs centering in Chicago; Isaac L. Ellwood, who was one of the original patentees of the barbed wire fence, out of which the redoubtable John W. Gates made his first stake; John Lambert, president of the Illinois Steel Co., and others. These gentlemen acquired a large interest in the Mines Company of America on a basis of $1,300,000 for the property, this consideration including a one-sixth interest in the Dolores Mines Co., of Chihuahua, Mexico. Mines Company of America has paid $3,785,000 in dividends, besides distributing the Dolores shares as a dividend. Recently the company has been paying 3% quarterly. The larger insiders are supposed to have sold their shares at the higher prices prevailing when dividends were larger. Now a consolidation is to be effected. The capital stock of the Mines Company of America is to be increased to $9,000,000, par $10, as against its present $2,000,000, par $1. The additional capital so provided is to be used in acquiring a controlling interest in Dolores by an exchange of ten shares of Mines Company stock for one share of Dolores and seven shares of El Rayo. The Dolores is situated in Chihuahua and is controlled by the same interests that control the Mines Company of America. It has a capital of $2,000,000, par $5, and has paid in dividends about $1,000,000. The El Rayo is likewise situated in Chihuahua, it is a recently developed property and has paid but three or four dividends aggregating about $50,000. The quarterly report just issued shows a net profit of $66,698 derived from 13,700 tons of ore averaging in value $13.96 per ton. El Rayo is controlled by W. B. Thompson, who was prominent in Cumberland Ely, Nipissing, LaRose, Inspiration, and Mason Valley, and W. Hinckle Smith, of Philadelphia, who is one of the important factors in Nevada. Prior to the re-making of Mines Company of America into a holding company three members of the new merger each acquired a one-third interest in the LaDura properties on the Yaqui river in Sonora. George A. Schroter has occupied the position of consulting engineer for the companies mentioned and will continue to act as such for the consolidation. The real importance of the move here discussed is not particularly in the consolidation of the properties mentioned but in the creation of so large a holding company backed by such intrests. It is intended to make the Mines Company of America one of the most important proprietary and development companies operating in Mexico. The new company will have more than ample capital for its operations and may be expected to become an important factor in Mexican mining.

The dearth of news from Porcupine and the lack of endorsement by such competent engineers as have visited the camp indicates a failure for the new Goldfield. There does not appear to be any life in such reports as are made and the verdict now seems to be that Porcupine will prove a disappointment. California oil promotions are coming East in increasing numbers and the showings are such that Eastern capital and financial institutions here with London connections are beginning to take an added interest in the possibilities presented.

General Mining News

ARIZONA

COCHISE COUNTY

Two new orebodies have been opened in the Shattuck-Arizona mine at Bisbee within the past few weeks; the raises from the 600 to the 500-ft. level both having cut ore that assays 35% copper with considerable manganese. The company is shipping about 150 tons of high-grade ore per day but it is reported that the shipments are to be increased and the grade lowered by mixing the low-grade material that is now left in the mine.——The two electric pumps at the 500-ft. level of the Holbrook shaft of the Copper Queen have been lowered to the 600 and another large pump installed to handle the water during the wet season. The company is operating a diamond-drill on the Silverton claim at Courtland.——Sinking has been started in the Irish Mag shaft of the Calumet & Arizona at the 1250-ft. level, and will be continued 200 ft., stations being cut on the 1350 and 1450-ft. levels.——The C. O. D. company at Courtland shipped a carload of ore to the Douglas smelter that averaged about 20% copper.——The Bisbee-Sonora company has just completed 1000 ft. of development at Paradise, in which it has cut the orebody in several places. This company has been at work since opening its mine three years ago, and is now ready to install machinery.——The Whitetail mine which has been recently taken over by a new company, has opened a good body of lead-silver ore on the 120-ft. level and are now grading for the installation of a new power-plant.

GILA COUNTY

(Special Correspondence).—The drift following the stringer of ore on the 660-ft. level of the National Mining Exploration property has advanced westward 180 ft., the present breast showing the vein to be 30 in. wide. Beginning June 26, sinking of the shaft will be resumed at its present depth of 708 ft.——The McGaw shaft of the Superior & Boston Copper Co. has been sunk 163 ft. below the sixth level. The west winze put down from the fourth level of the Gardner workings is still sinking in ore on the Black Oxide vein averaging 8% copper.——Churn-drill hole No. 5, situated 1100 ft. west of the shaft on the property of the Live Oak Development Co., cut ore 320 ft. from the surface, and is still in schist with an average copper content of over 2%, at the depth of 425 ft. Hole No. 7 is being drilled 700 ft. south of the shaft, and is still in granite 65 ft. from the surface.——The output of the Old Dominion smelter for May was 2,150,000 lb. of copper, and it is estimated by the management that nearly the same amount of copper will be produced during June. Three blast-furnaces are being kept in operation.——The vein recently opened on the 650-ft. level of the Superior & Globe property, at a distance of 475 ft. north of the shaft, is 5 ft. wide. This vein contains much hematite, but few traces of copper. Along the foot-wall, some native silver was found. The company will soon have a diamond-drill at work prospecting. H. V. Snell is superintendent.

Globe, June 18.

MOHAVE COUNTY

Sinking is now under way at the Summit mine of the Needles Mining & Smelting Co. on the summit of the Cerbat range north of Stockton hill. The vein is one of the largest in that district, the cross-cuts having opened 16 ft. of ore that contains lead, gold, and silver, with about 40% iron which makes it ideal for the work at the smelter.——The station has been cut on the 200-ft. level of the C. O. D. mine and a cross-cut is being driven to the vein.——The Arizona Turquoise Co. has nearly completed the road into I X L basin and will commence the work of hauling in the machinery and cleaning out the old I X L mine early next month.——The Golconda mine in the Union Basin district paid another dividend several days ago of 1% per share, making the seventh of its kind in about as many months. In five months ended May 31, the mine shipped 4395 tons of ore netting about $87,000 above freight and smelter charges. ——In the new shaft of the Tennessee at Chloride three shifts are making 25 ft. per week. It is down 120 ft. and will be continued to 500 ft. before any stations are cut.——The ore opened in the Keystone last week is holding up both in size and value as driving progresses. Shipping of the high-grade ore has been started, and, pending the completion of a railroad spur, six tons per day are being hauled to Chloride and from there shipped to the Needles smelter.

PIMA COUNTY

The Gould Mining Co. is completing plans for the erection of a smelter at the Gould mine, 18 miles west of Tucson, and will commence work repairing the wagon-road so the machinery can be hauled in. The plant will be so situated that it can draw on a large area for custom ore and it is thought that the mines of the district will supply an ample tonnage without shipping in any ore from the outside.

YAVAPAI COUNTY

A triplex electric station pump has been ordered by the Arizona Central Copper Co. from the Arizona Mine Supply Co. for its mine in the Black hills near Dewey. Up to the present time the flow of water has been small, being handled entirely by the skip. A much stronger flow has now been opened and the new pump will be placed at the 900-ft. level while the shaft is being sunk to the 1000. J. B. Cleveland is manager for the company.——The Mount Elliot Consolidated Mines Co., which recently remodeled its mill, has completed the connection to the wires of the Arizona Power Co., and the camp is now supplied with electricity for light as well as power. The pole-line is now being constructed to several of the other camps in the district.

YUMA COUNTY

It is reported that the Lewisohn interests which took over the old Planet mine at Planet about a year ago are to replace the 30-ton furnace at the mine with a large and modern plant, and that work on a spur from the Arizona & California railroad to the town will be started this fall. A 600-ft. shaft has been sunk on the property and over 1000 ft. of drifts driven under the present management. The churn-drills now operating have been in ore for some time.

CALIFORNIA

CALAVERAS COUNTY

(Special Correspondence).—The Calaveras Copper Co. is pushing development on its properties in the Copperopolis district. The Union shaft is down 800 ft., and has opened a body of ore assaying 9 to 12% copper in the north drift which is being extended to open a 40-ft. body of ore that was intersected by a winze from the ninth level. The Keystone Discovery shaft is down 600 ft., is triple-compartment and will be the main working avenue. The North Keystone mine is being opened by a new shaft, down about 265 ft.——A new reverberatory furnace was recently installed at the Campo Seco smelter, and activities throughout the copper fields of the county are more pronounced at this time than for many years.

San Andreas, June 20.

New York interests have secured a three-year bond on the Ophir Consolidated mine in the San Andreas district and work has been started on an adit that will open the vein at a vertical depth of 300 ft. The property is near the Foot & Thompson mine where a $15,000 pocket was opened a short time ago.——The Sierra Nevada Water Co. is to resume work on its power-plant site on the Mokelumne river between West Point and Rail Road Flat.——There are 500 tons of milling ore stored at the Newman mine near West Point that will be run through the 10-stamp mill in a short time, and 80 tons of sulphide ore that will be shipped to the smelter for treatment.——George Porteous has hauled about 20 tons of ore to the Thompson mill and is to ship four or five tons to the Selby plant.——It is reported that the Blue Mountain mine, formerly known as the Heckendorn, is to be re-opened.——Brady & Cethel have completed retimbering their property at Murphys and expect to open milling ore at an early date.

INYO COUNTY

The old Union mine in the Russ district has been bonded to the Mortimer Mining Co., of Philadelphia, and preparations are being made to re-open the property. Six men are

now at work and the force will soon be doubled.——The Four Metals Mining & Smelting Co., operating near Keeler, have suspended work temporarily.——At the Loretta mine the shaft which is being sunk to the 750-ft. level is now down 475 ft. The vein is almost perpendicular and the shaft is being sunk parallel to it, cross-cuts being driven every 100 ft. The ore opened on the 400-ft. level averaged 5% copper.——The adit at the Maverick is in 450 ft. with some 300 ft. additional before the main vein is opened.——The new mill at the Buckeye has been started and is reported to be running smoothly.

LOS ANGELES COUNTY

The Sierra Madre Club, of Los Angeles, will be the host of the American Mining Congress from September 26 to October 1 of this year, when the annual convention will be in session.

NEVADA COUNTY

The shaft at the Cassidy is going down steadily in $35 ore. The company has installed a 50-hp. boiler to facilitate in pumping, as considerable water has been met lately.—— The Gaston Mining Co., which recently completed a long drainage adit to the old workings, is preparing to unwater the lower portion of the mine and will commence blocking out ore to keep the 40-stamp mill busy.——The North Star Mines Co., at Grass Valley, paid a 5% dividend of $125,000 on June 18, making a total this year of $200,000 as a 3% dividend was paid March 30.

PLACER COUNTY

A 245-ft. cross-cut to the old adit at the Kimball mine has been completed and the old workings are being cleaned out. ——Three shifts are at work in the adit at the Mayflower which will open a large amount of ground that has never been tested.——The blue lead has been cut in the Glenn mine on Duncan ridge.——Frank Bonham has finished the 250-ft. adit to the channel on his claim in Indian canyon and is now opening pay gravel.——The London & Placer County Development Co. has been organized to prospect the veins opened by the grading on the Southern Pacific railroad. The first ground to be taken over is that of Mrs. Gertrude D. Nicol, near Weimar.

SAN BERNARDINO COUNTY

There are about 25 men working at the Gold Mountain mine at Victorville and the 40-stamp mill is running night and day.

SHASTA COUNTY

A compromise has been effected by the Delta Consolidated Gold Mining Co., and the Inca Treasure Mining Co., operating near Delta, in the suits that have hampered the work on both properties for the past year and the cases have been dismissed by Judge J. E. Barber.——Nearly a quarter of a million shares of stock in the Sibyl Mining Co. was sold at auction at Redding to reimburse the holders of several notes of G. A. Von Kruse who had given the stock as security for the notes.

SIERRA COUNTY

The bond on the Red Star mine at Alleghany which is held by Colorado interests has been extended and work will be resumed on the property. An adit is now in over 3000 ft. cutting several veins that prospect well and work will be centered on this till it cuts the vein that is supposed to be the extension of the Tightner.——The company sinking the shaft at Poker Flat has installed a new ¾-in. cable and is continuing the work at a depth of 275 ft.——Machinery for the addition of 10 stamps to the Chipps mill is on the ground and construction will be started as soon as the lumber can be hauled to the mine.——Preparations have been completed for the resumption of active work at the Gibraltar early in July.——It is reported that a new vein has been opened in the hanging wall of the old Sierra Buttes east of Downieville, and that the No. 9 mill will be started.——Work for the season is soon to be started on the Phoenix mine above Sierra City.——Truax, Camp & Ish are figuring on erecting a 2-stamp mill on the Sargent property in Slate Castle ravine which they are opening under bond as a shoot of high-grade ore has been opened.——The air shaft at the Bunker Hill has been completed and work started in the long bedrock adit that is being driven to tap the gravel.——The Bullion mine west of Sierra City is being sampled and upon the results depend the action that will be taken on the property.——The drift at the Ramshorn group is opening a shoot that assays high in copper.——The drift at the Gladstone mine near Gibsonville has opened the vein showing 2 ft. of high-grade ore samples from which have assayed as high as $350 per ton. The company has been developing the property for some time and will erect a 10-stamp mill, and possibly a cyanide annex, in a short time. Charles Root is superintendent.

SISKIYOU COUNTY

Albert C. Aiken, W. A. Graham, and associates have purchased the Boggett placer claim two miles above Oak Bar and are planning to work the ground with a steam-shovel. ——Francis McCarthy opened a rich pocket in the Scott's Bar district a short time ago.——F. H. Osgood, of Seattle, purchased the claim in which the Fiddler Brothers were interested near Yreka for $5000.

TRINITY COUNTY

(Special Correspondence).—The 40-stamp cyanide mill under construction by the Trinity Gold Mining & Reduction Co., at its Headlight mine near Carrville, is now half finished and will be hastened to completion as rapidly as possible. It will include in its equipment two Oliver slime filters and four Dorr thickeners, but there will be no plates or concentrators as all ore is to be cyanided. The Merrill system of zinc precipitation will be employed. Seventy tons

Central Portion of Northern California.

of machinery have already been brought in. Power will be supplied by a 500-hp. hydro-electric plant that the company is to build on the west side of Trinity river just north of Carrville. The flume to bring the water from Coffee creek is now under construction. This will be ample for all purposes with some to spare for outside demands. A compressor will also be installed at the mine to operate 5 drills. It is the intention to have the entire plant in running order by November 1. David Goodale, assistant manager, is in charge of the work.——Reed & Chapman have installed an 8-ton cyanide plant on their Windy Camp claim in the Coffee Creek district. The vein carries 15 oz. gold per ton.

Carrville, June 13.

YUBA COUNTY

The California Mother Lode Mining Co., operating near Indian ranch, has ordered cyanide equipment to construct an annex to the mill that will treat 100 tons of ore per day, and expects to have the plant in operation by August 1. A Chilean mill has also been ordered that will re-grind the pulp from the stamps before it is sent to the cyanide tanks. Warren C. Wilkins is manager.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—A shipment of 800 lb. of ore from the Elephantine mine on Covode mountain was settled for at $180 per ton in gold. Drifting is in progress on a streak of mineral that is from 3 to 5 in. wide.——Stephens & Co., leasing in the upper workings of the Mendota mine from the Victoria adit level, have uncovered an 8-in. streak of galena that mills 175 oz. in silver with 45% in lead. The ground is being placed in condition preparatory to stoping.——Work has again been put under way in the carrying of the raise that is to connect the Scepter adit with the Sunburst workings.——The Marshall-Russell adit on Miller mountain, has been driven for 4500 ft. Driving has been started on the Neef vein cut 4200 ft. from the portal. ——The Silver Horn Mines Co. has been incorporated with a capitalization of $1,000,000, shares having a par value of $1 each. The Silver Horn group of seven patented claims is owned. The holdings are situated up Bard creek and in former years a heavy production was made. F. E. Wire is manager.——Cannady & Ford, operating under lease on the Katie Emmett, had down a 3-ton shipment of smelting ore last week that brought a settlement of $200 per ton.——The German mine up Virginia canyon has entered among the list of shippers. W. H. Bartow, operating under lease, had down four tons of ore last week that milled $190 per ton in gold and silver.

Idaho Springs, June 18.

GILPIN COUNTY

(Special Correspondence).—The Gilpin mill at Black Hawk is to be taken over by the owners of the Klein-German mine. The plant is to be remodeled throughout.——A 12-hp. gasoline engine has just been received at the Egyptian mine on Quartz hill. Heavy shipments of smelting ore are being made, the product being taken from the 150-ft. level.——It is reported that the Hughes mine on Bellevue mountain has been purchased by L. Hakeman, of London. The property is equipped with a modern plant of machinery while the shaft has been sunk to a depth of 300 ft.——The machinery at the Brooklyn mine is being overhauled, while the shaft-building is being remodeled. W. E. Scott, of Perigo, has been appoited manager.——The Daisy mill at Perigo has been started and the machinery is being fed upon ore from the Tip Top mine.——The Perigo mill is treating a heavy tonnage of ore from the War Eagle and Comstock mines in Independent district. The machinery at the New York mill at Black Hawk was brought into commission this week and will run on ore from the Pewabic mine in Russell district.

Central City, June 18.

LAKE COUNTY

Work is to be started in the old Monarch mine at Leadville as soon as the pump in the Cleveland shaft has unwatered the ground.——An electric power-plant and air-compressor is to be installed at the Clear Grit shaft, and it is reported that a similar plant is to be placed on the Ella Beeler ground adjoining and power-drills used underground.——Harry Mamlock has made considerable improvement in the surface plant at the Dorris mine, and has completed arrangements to resume work on the lower levels which have good production records.——Work has been put under way at the G. M. Favorite, one of the old-time producers of Iowa gulch, and operations will be in full blast in the course of the next few weeks.——The Dinero shaft has been tapped by a bore-hole from the Dinero adit on Sugar Loaf mountain and is now completely drained. No effort has been made by the management to cross-cut to the shaft as yet as all attention is directed to getting out shipping ore from the north drift.——The lessees of the La Plata shaft are shipping 25 tons of oxidized ore per day that averages $10 per ton.

TELLER COUNTY

The shoot which Ed. Cookerly opened a few weeks ago on Prince Albert ground in the Cripple Creek district continues to improve as the cut is advanced on the vein. A drift will be driven to determine the length of the shoot and a winze put down on the ore, which is 4 ft. wide in the cut and assays about $35 per ton.——The Furst Brothers, of Victor, who have a lease on the Dead Pine claim of the Ophir Mining & Milling Co., have opened a shoot of smelting ore at the eighth level that assays from $25 to $40 per ton, with screenings that run as high as $100 per ton.——The Pinnacle Leasing Co., operating the Mitchell mine on Bull hill, is erecting new ore-bins and will increase the shipments from the mine.——Leonard Worcester and associates, who have a sub-lease on the Conundrum mine on the western slope of Gold hill, opened a shoot on the seventh level that is from 10 to 12 ft. wide and are now stoping for shipment.——Sub-lessees, operating on the eighth level of the main shaft of the Hidden Treasure property, have cut a shoot that will assay from 3 to 5 oz. gold per ton and are saving the ore for shipment.

IDAHO

SHOSHONE COUNTY

The Federal Mining & Smelting Co. is negotiating for the purchase of the Star, a partly developed lead-silver property adjoining the Morning mine at Mullan, also the Flynn group of 30 claims, situated between the Frisco and Morning mines in the Coeur d'Alene district. The Star has developed a large orebody to a depth of 800 ft. which ranges from 15 to 18 ft. in width. The Flynn groups are west of the Star.——J. J. Stanford, of Wallace, engineer for the Silica Gold & Copper Co., reports that the first vein cut by the cross-cut is 16 ft. wide, with a pay-streak of 4 ft. that assays 4.3% copper. Ore in the upper portion of the vein assays up to $12 in gold.——The Snowstorm Mining Co. paid a dividend of $22,500, at the rate of 1½c. per share, on 1,500,000 shares on June 20.——C. L. Cowell, of Missoula, Montana, president of the Marsh Mining Co., announces that work with the new electric hoisting machinery has started on the property near Burke, three shifts being employed. The vein averages 4 ft. in width, 2 ft. of which is good shipping ore. It adjoins the old Tiger-Poorman and is soon to be equipped with a mill and additional machinery.

MISSOURI

JASPER COUNTY

Following a shut-down of several months, the Hallowe'en mine, on the McCown land at Spring City, is to resume operations. The mine has several drifts opened below the 150-ft. level, the ore being of high quality and occurring in rich blanket veins, this property showing one of the best marked blanket formations of that district. The mill is in good shape, and the only thing standing in the way of immediate operations is the need of pumping, the drifts having become flooded during the long shut-down.——The directors of the Tiwah Mining Co., operating on a tract at Galena, have decided to purchase from the Nowata company the Kenwood mill at Miami, which recently was taken over by the Nowata company, the intention at that time being to move the plant to the West Joplin tract, which is showing such good ore. The Tiwah company is to begin the moving of the mill to Galena soon. The plant is one of the complete ones in the Miami district, but has been idle for some time.

MONTANA

LEWIS AND CLARK COUNTY

Work is being rushed on the Hauser Lake dam and hydro-electric plant of the United Missouri River Power Co. near Helena, and it is thought that the machinery will be ready for operation by fall. A total of 91,000 hp. will be developed at the lake. Besides supplying mines, highways, and factories, the United company proposes to use electric power for the raising of water to the bench lands for irrigation along the Missouri river and in Prickly Pear valley. The plan is to hoist this water by pumps and then store it in reservoirs on the foothills, reclaiming about 100,000 acres of rich lands. When the company began to furnish power to the Butte mines, the transmission proved so successful that the original Canyon Ferry plant was enlarged from 4000 to 10,000 hp. and the lines extended to the Washoe smelter. The Canyon Ferry dam now produces a head of 38 ft., and its reservoir, known as Lake

Sewell, covers 6½ square miles. The first Hauser Lake dam was commenced in July 1905, and completed in January 1907. A year later this plant was developing 16,000 hp., which was increased by a fifth turbine to 20,000 hp. On April 14, 1908, a big rise in the Missouri destroyed the dam and caused immense damage. In July of the same year the company started to reconstruct, and the broken dam has now been replaced with a solid concrete foundation from bedrock. A large portion of it is 50 ft. below the natural level of the river. When finished, the dam will be 100 ft. high from the lowest foundation and will impound water 65 ft., while the reservoir produced will cover 9 square miles, extending 18 miles southward to Canyon Ferry dam and up Prickly Pear valley to within 8 miles of Helena. The power-house at Hauser Lake, which was not damaged much, has been repaired. Water from the reservoir is led into a canal and thence through girds, designed to keep out driftwood, into five turbines driving 4000-hp. generators. Transformers change the current from 2400 to 70,000 volts.

NEVADA

CLARK COUNTY

The Spokane-Searchlight in the Searchlight district is now driving east on the third level, having cut through the fault and picked up the vein beyond.——The Searchlight Mining & Milling Co. will complete the re-timbering and aligning of its shaft the early part of July and will erect a new steel head-frame. A station pump with a capacity of 500 gal. per minute and a 125-hp. gasoline engine will be installed.——Smith & Fessler ran a small lot of ore from their lease on the I. X. L. ground through the mill with good results.

ESMERALDA COUNTY

(Special Correspondence).—The Hydro-Electric Power Co. of Bodie, California, is arranging to run a transmission line to Rawhide to furnish light and power to the town and mines. It is expected to commence construction work shortly.——The Rawhide Queen Mining Co. has placed a force of men at work on the old Dromiac lease and is working from the 125-ft. level.——The St. Ives lease on Queen ground is developing a 4-ft. vein of rich ore on the 450-ft. level, obtaining assays from $40 to $250 per ton. A 25-hp. compressor has been installed and a 100-ton capacity ore-bin constructed.——The Truett-Rawhide lease recently shipped 500 tons of ore to the National mill, and is now delivering 500 tons to the Klinker plant. E. C. Klinker, manager of the Klinker mill, states that a cyanide plant will be shortly installed.——The Grutt-Balloon Hill lease on the Queen has opened 4 ft. of ore at a depth of 350 ft. Silver predominates and the ore will have to be held until some of the local plants install cyanide departments.——The Victor mill is running steadily on ore from the Proskey lease.——The Schmidt-Loufek lease is sending small consignments of $25 ore to the National mill.

Rawhide, June 17.

The three-compartment shaft of the Goldfield Annex lease on the Polverde claim of the Jumbo Extension, which is going down between 3 and 4 ft. per day, is now well past the 900-ft. mark. A station will be cut at the 1000-ft. level and the vein explored from that point to pick up the shoot that was opened on the 800.——At the Goldfield Consolidated mill 80 stamps are now dropping and it is stated that 700 tons per day is being crushed, while shipments of high-grade ore to the smelters from the Clermont keep up the regular output.——The Combination Fraction is again on the producing list, having started the 20 stamps in the leased mill. Considerable repair work was found necessary in the plant, but now it is in good running order and is expected to run smoothly. Underground the ore is being drawn from the stopes between the 280 and 380-ft. levels, and from the 500 and 750-ft. workings.——The shaft on the Victor claim of the C. O. D. Consolidated has been re-timbered to the 485-ft. level and the drifts on the 400 and 485 cleaned out. There is considerable milling ore opened and it is thought that the company will erect a plant to handle its ores.——Three sets of lessees are working on the Diamondfield Black Butte and the ore is being stored for shipment.

LANDER COUNTY

The three-compartment shaft of the Kimberly Consolidated Mines Co. has opened a number of stringers of copper sulphide and carbonate, with some gold and silver in the quartzite. The company is also preparing to sink a two-compartment shaft on the Golden Rule group, which is under its control.——The district has been granted a post office, and mail should now be addressed to Kimball.

LINCOLN COUNTY

R. W. Miller has succeeded in interesting Eastern capitalists in his property near Crescent, and the ore is now being tested to determine the best method for treatment to be installed in the contemplated plant. A large open-cut has been run on the vein, opening ore that assays between $12 and $15 per ton.——Fred Falkner, receiver for the defunct Bamber-Delamar Gold Mining Co. will sell the remaining machinery in the mill and the claims about the middle of July. The power-plant at Stine is being dismantled under the supervision of George M. Baker and will be shipped to Ogden by the Salt Lake & Ogden Railroad Co. which purchased it some time ago.——Jim Lee and Ed. Hing, who have a lease on the Zip Coon and Golden Eagle claims have over 100 tons of $40 ore on the dump and have opened several shoots of high-grade in the underground work.——Repairs on the main line of the Salt Lake route have been completed and regular trains are now running. On the Pioche branch the work is well under way and trains are expected to be in regular operation in a short time. This means much for this district, as a number of mines have been idle or confined operations to small amounts of development on account of high cost of supplies while the railroad was not in operation. In most of these considerable ore is blocked out and shipping will be resumed at once.

WHITE PINE COUNTY

The machinery for the new mill of the Nevada Amalgamated Mines Co. is now on the Willowpath mill-site near Black Horse, and the lumber is being hauled from Ely. It is anticipated that the mill will be completed this fall, when it will be prepared to operate on custom ore as well as that from the company's mines.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—A new filter-press is being installed at the Socorro mines which will increase the capacity of the plant to 150 tons of ore per day. The drift on the 600-ft. level and the raise from the 500 have both opened ore that assays from $39 to $50 per ton.——Last week the Ernestine Mining Co. treated 680 tons of ore, producing 60 sacks of concentrate. The mill is reported to be making an excellent saving, the tailing assaying from 65 to 95c. per ton.——The station on the 400-ft. level of the Deadwood mine is being enlarged to accommodate the new pump which the company is to install to handle the water during the wet season.

Mogollon, June 17.

SOUTH DAKOTA

CUSTER COUNTY

(Special Correspondence).—The Ideal mine is situated about 12 miles northeast from the town of Custer, on a high mountain, at the foot of which flows what is called Iron creek. On this mountain are two groups of mines, the Bessie and the Rushville, consisting of 60 claims owned by the Ideal Mining & Milling Co., whose officers mostly reside in Indianapolis. They are to be opened by an adit now in 700 ft., and with 500 ft. still to be run before striking the main vein. This, from all indications, is about 600 ft. in width and consists of a large belt of quartzite which conforms in strike with the old micacious slates which form the country rock. A granite dike of a coarsely crystallized character forms one wall of the main vein, and it, in common with the quartzite, is vertical. Assays have been obtained from the whole width of the quartzite running from a trace to $480 per ton in gold, and it is estimated

that this body of ore will mill about $6 per ton. Numerous drifts have been run from the adit both north and south, all of which are in ore, showing an average assay reported as $10 per ton in gold. The mine is equipped at present with a mill of 80 tons per day capacity, made by the Downie-Wright Co., of Rapid City. A 12-ft. slow-speed Chilean mill is used for crushing. It is expected that the mill will be ready to run about July 10. The ore is a sulphide, not free milling, and cyanide will be used in its reduction. Water will be obtained from Iron creek and there is plenty of timber on the ground. George Van Camp is the president. R. F. Conover, general manager, and his son, A. B. Conover, assistant.

Custer, June 17.

UTAH

BEAVER COUNTY

The raise on the orebody recently opened on the 500-ft. level of the Cedar Talisman is now up over 40 ft. in high-grade ore. This has been especially satisfactory to the management as the raise was started for an air-connection rather than to open the ore.——The drift on the 200-ft. level of the Michigan mine has opened a 12-in. stringer of ore that assays 50% lead with 70 oz. of silver per ton and a shipment will soon be forwarded to one of the smelters.

JUAB COUNTY

The output of Centennial-Eureka at Eureka, which is normally 40 or 50 carloads per week, has been curtailed recently while preparing for the installation of a new pumping plant.——The Gemini Mining Co.'s large electric pump which was broken some time ago and sent to the factory for repairs has been returned and is now being installed in the mine.——Work is to be resumed in the Crown Point early in July.——The head-frame at the Bradley in North Tintic has been completed and the new gasoline hoist installed. The property is now under the supervision of S. E. Ware.——Work at the Beck Tunnel property has been suspended as the return from the ore shipped has fallen considerably below the operating expenses of the mine. It is probable that an assessment will be levied on the stock and work resumed as soon as sufficient money is raised.

SUMMIT COUNTY

The Daly-Judge company at Park City has installed an air-lift at the 1500-ft. level of the mine and will attempt to unwater the ground to the 1600 where rich orebodies were reported before the miners were driven out by an excessive flow of water.——In a circular letter to the stockholders of the Silver King Consolidated it is stated that the mine is in excellent condition and that prospects for opening commercial ore are good. To raise $50,000 to carry on the development work the company is to issue several notes which are to be redeemable in stock of the company at par any time prior to their maturity.——Rapid progress is being made in the tunnel of the Snake Creek Mining & Tunneling Co., the face being now in about 375 ft.——An assessment has been levied on the Scottish Chief stock and work is to be resumed in the face of the adit which lacks about 100 ft. of cutting the contact on which the ore is thought to be developed.

SALT LAKE COUNTY

The directors of the Utah Copper Co. have voted an issue of $2,500,000 first-mortgage 6% bonds by the Bingham & Garfield Railway Company.

TOOELE COUNTY

The adit at the Boston Consolidated Mining Co.'s property on the east slope of Lion hill in the Ophir district is now in about 575 ft., and is expected to cut the ore in about 200 ft. The company is working under considerable difficulty as the ore is now hoisted to the adit-level 185 ft. with a windlass. The ore in the bottom of the winze is a decomposed lime-quartz with large bunches of high-grade chloride of silver.

UTAH COUNTY

The Bonneville Mining Co. has been incorporated at Provo and has commenced work on an adit on the Crandall property between Provo and Springville. The Knight interests are the controlling factors in the company and the work will be under the supervision of George A. Storrs.

WASHINGTON

FERRY COUNTY

James L. Harper, general manager of the Republic Mines Corporation, operating the Lone Pine-Pearl-Surprise group in Republic, announced at the annual meeting in Spokane on June 15 that the second dividend will be disbursed in July. He reported that the mines produced more than 4000 tons of ore since January, the net value of which is placed at approximately $101,482, exclusive of ore at the smelter and in transit, upon which the return has not been received. He estimates this will add $45,000 to the gross value of $139,573.

JEFFERSON COUNTY

Work is progressing satisfactorily on the Tubal Cain property at Iron Mountain. The adit is now in over 1300 ft., and the management expects to open a good body of ore in a short time.

MEXICO

JALISCO

The experimental mill erected at the Peginto mine in the western portion of the State is crushing from six to eight tons of ore per day. The pulp is run over the plates and treated with cyanide, a total extraction of 85% being obtained. There is a large tonnage of ore blocked out in the mine and it is probable that a larger mill will be erected by the owners, H. H. Cross and H. W. Young.

Amparo Mill, Jalisco.

PUEBLO

The Teziutlan Copper Co.'s new plant at Teziutlan which has been in operation for about two months is now running at good capacity and 2500 men are working. The plant has been under reconstruction for nearly two years and is said to be one of the best of its kind in the republic. There are two furnaces of 500 tons capacity each and a completely equipped converting plant to produce blister copper. All machinery is driven by electricity in both the mines and smelter, the current being generated at a hydro-electric station under a 1000-ft. head. The property has been shipping copper to New York for several weeks, and shipments will increase as the efficiency of the plant is raised. R. L. Lloyd, formerly superintendent at the Greene-Cananea plant, is superintendent and T. C. Saunders, formerly in charge of Los Ocotes mines belonging to the same company at Ejutla, Oaxaca will be in charge of the mines. These have a capacity of 12,000 to 15,000 tons per month. The company has its own railway from the mines to Teziutlan, a distance of ten miles.

SONORA

The Sonora Exploration Co. has been organized to take over the Antigua, Texas, Last Chance, and the claims operated by the Florida Copper Co., in the Tigre district south of Douglas. The company is composed largely of New York interests and will commence work on the claims at an early date.——The La Cobriza Mining Co. has commenced work on the smelting plant which is to be erected at the mine two miles west of Noria, and is having the machinery for the furnace built at El Paso. Fred C. Emery is manager. ——At the Santa Fe mine, nine miles south of Cananea, considerable work is being done, though operations are somewhat retarded on account of the experiments to determine the best method of treatment for the ore which is high-grade lead-silver-zinc.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. F. KEMP is at Lake George, New York.

F. W. BRADLEY was at Goldfield this week.

J. H. MCKENZIE has returned from Nicaragua.

J. MORGAN CLEMENTS has returned to New York.

NORMAN C. STINES has returned from Death Valley.

GEORGE B. STARR visited Goldfield, Nevada, this week.

C. W. MERRILL has returned from New York and the East.

CLARENCE B. OSBORNE has returned to Los Angeles from Cuba.

G. B. STREET has left San Francisco for Wilmington, Delaware.

J. P. KEENE is investigating oil lands at Matsqui, British Columbia.

T. LANE CARTER, of OSGOOD, CARTER & Co., is examining mines in Nevada.

C. C. O'LOUGHLIN is at the Bogardus Testing Laboratories, Seattle, Washington.

O. H. PACKER has gone to Minaret, Inyo county, for a month's stay examining properties.

R. B. BRINSMADE is in the Rainy Lake district of Ontario, making examinations for West Virginia investors.

W. M. CAHOONE, formerly with the Bunker Hill & Sullivan M. & C. Co., is now with the Tri-Metal Co., Benton, California.

S. H. BROCKUNIER, of Wheeling, West Virginia, has finished his examination of the Erie and Aucho mines near Graniteville, Nevada county, California, and has returned to his home.

J. B. STEWART, formerly of El Oro and Guanajuato, Mexico, has joined the CONSTANT HERZIG Co., and will be in charge of the metallurgical department, making a specialty of cyanide work.

FRANK O. JAMES, formerly with the Butters Copala mines, at Copala, Mexico, and lately with the Guanajuato Amalgamated Gold Mines Co., is now in charge of the cyanide department of the Yoquiro Development Co., in Chihuahua.

W. J. ADAMS, who died at San Francisco, June 10, was born at New York City in 1855. He was for many years identified with the mining industry of the West being especially well known through his useful little book, 'Hints on Amalgamation'.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

C. H. S., Chafey, Nevada: Vein quartz with actinolite.

L. L., Chihuahua, Mexico: The rock is sedimentary limestone.

C. F., Gaston, California: No. 1 and 2, two phases of granodiorite.

W. A., Reveille, Nevada: Fine grained decomposed silicious rock, probably the result of the decomposition of a rhyolite or chert.

H. O. J., Bowman, California: No. 13, fine grained silicious rock, too much altered for further classification. The yellow mineral is not an ore of uranium.

Dividends.

On Friday, June 3, 1910, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 153 of $98,100. This makes the amount of dividends paid since January 1, 1910, $451,200, and the total to date $11,737,200.
